EXAMPLES OF SILVERSMITHS' WORK

1. Silver-gilt cup designed by John Flaxman, 1812 and made by Paul Storr
2. Modern cocktail set of shaker, six glasses, tray and measure
3. Sterling silver Guild cup, English and continental adaption
4. Reproduction in sterling silver of an early American teapot, sugar bowl and cream pitcher
5. Silver service of modern design ornamented with ivory or lapis-lazuli balls
6. Hand chased tea service
7. Hot water jug and coffee pot of silver with chased decorations and fibre handles and knobs

CONTEMPORARY DESIGNS IN SILVER AND OTHER METALS

1. A pitcher and two cups by Georg Jensen
2. Teapot, candelabrum, ladle and jar, the work of Georg Jensen
3. Left: Brass biscuit box with silver-plated interior. Right: Biscuit box in gilding metal, with silver-plated interior. Centre: Copper fruit dish. Group designed and made by Gordon Russell, Broadway, Worcestershire
4. Silver vase with ornamental lid, designed by Prof. Kai Gottlob and made by Evald Neilsen, Copenhagen
5. Silver bonbonnières made by A. Michelsen (Danish)

BY COURTESY OF THE GORHAM MANUFACTURING COMPANY

PROCESSES IN WORKING SILVER AND GOLD

1. Heating and alloying the silver in an American plant. The silver is placed in a crucible, mixed with other metals in the proper proportions, and melted in the furnace
2. Shaping a sheet of sterling silver. The design to be worked into the silver tray is seen on the wall in the background
3. Skilled worker in silverware plant drawing the design on a teapot preparatory to working
4. Silver chaser using the snarling iron. A snarling iron has a long beak and is used in making raised work on silverware. The worker is holding one end of the snarling iron in a vise and striking the shank with a hammer. It makes its impression on the rebound from the inside

BY COURTESY OF THE GORHAM MANUFACTURING COMPANY

DIFFERENT PROCESSES OF SILVER WORK

1. Skilled workman engraving with a graver elaborate design on a silver tray. 2. Soldering the top on a silver candlestick. 3. Erik Magnussen, noted European designer now devoting himself to development of artcrafts in America, hand-chasing a sterling silver vase. A new and modern motif is expressed in his work. 4. Stamping the Hall Mark on a finished piece of silverware. The Hall Mark is used to identify the maker of the piece and the date, and to attest to the purity of the silver

SILVER-TREE (*Leucodendron argenteum*), a South African tree, the leaves of which are covered with fine silky hairs, and are used for painting on. The tree has been nearly exterminated. There are about 70 species of the genus *Leucodendron* (family Proteaceae) all South African.

SILVESTER I., pope, bishop of Rome from Jan. 314 to Dec. 335, succeeded Melchiades and was followed by Marcus. The story of his having baptized Constantine is pure fiction, as almost contemporary evidence shows the emperor to have received this rite near Nicomedia at the hands of Eusebius, bishop of that city. The so-called *Donation of Constantine* (*q.v.*) was long ago shown to be spurious, but the document is of very considerable antiquity. It was certainly known to Pope Adrian in 778, and was inserted in the false decretals towards the middle of the next century.

SILVESTER II. (Gerbert), pope from 999 till 1003, famous under his original name of Gerbert, first as a teacher and afterwards as archbishop successively of Reims and Ravenna, was an Aquitanian by birth, and was educated at the abbey of St. Gerold in Aurillac. Here he seems to have had Gerald for his abbot and Raymond for his instructor, both of whom were among the most trusted correspondents of his later life. He visited Rome about 971 in company with his two patrons Count Borel of Barcelona and Bishop Otho of Ausona. When brought before the emperor Otto I., Gerbert admitted his skill in all branches of the quadrivium, but lamented his comparative ignorance of logic. He went to continue his studies under Adalbero at Reims, where he seems to have studied and lectured for many years, having amongst his pupils Robert, afterwards king of France, and Richer. Gerbert's fame spread over Gaul, Germany and Italy, till it roused the envy of Otric of Saxony (Octricus of Magdeburg), who, suspecting that Gerbert erred in his classification of the sciences, sent one of his own pupils to Reims as a spy, and then accused Gerbert of his error before Otto II. The emperor commanded the two scholars to appear before him at Ravenna, about Christmas 980, and the disputation lasted, we are told, a whole day. Otto II. appears to have given Gerbert the abbey of Bobbio, but the abbot found difficulty in collecting his dues, and returned to Reims as secretary to Adalbero.

According to M. Olleris's arrangement of Gerbert's letters, he was at Mantua and Rome in 985. The archbishop died on Jan. 23, 989, having, according to his secretary's account, designated Gerbert his successor. But the influence of the empress Theophana, mother of Otto III., secured the appointment for Arnulf, a bastard son of Lothair. The new prelate took the oath of fealty to Hugh Capet and persuaded Gerbert to remain with him. When Charles of Lorraine, Arnulf's uncle, and the son of Louis IV. D'Outremer, surprised Reims in the autumn of the same year, Gerbert fell into his hands and for a time continued to serve Arnulf, who had gone over to his uncle's side. He had, however, returned to his allegiance to the house of Capet before the fall of Laon placed both Arnulf and Charles at the mercy of the French king (March 991). Then followed the council of St. Basle, near Reims, at which Arnulf confessed his treason and was degraded from his office (June 17, 991). In return for his services Gerbert was elected to succeed the deposed bishop.

The episcopate of the new metropolitan was marked by a vigour and activity that were felt as far as Tours, Orleans and Paris. Meanwhile the friends of Arnulf were active in his behalf, and he is said to have been reinstated after the accession of Gregory V. In any case Gerbert seems to have left France towards the end of 995, as he was present at Otto III.'s coronation at Rome on May 21, 996. Somewhat later he became Otto's instructor in arithmetic, and had been appointed archbishop of Ravenna before May 998. Early in the next year he was elected pope (April 999), and took the title of Silvester II. Gerbert is generally credited with having fostered the splendid vision of a restored empire that now began to fill Otto's imagination.

Nor did Silvester II. confine himself to plans on a large scale. He is also found confirming his old rival Arnulf in the see of Reims; summoning Adalbero or Azelmus of Laon to Rome to answer for his crimes; judging between the archbishop of Mainz and the bishop of Hildesheim; besieging the revolted town of Cesena; flinging the count of Angoulême into prison for an offence against a bishop; confirming the privileges of Fulda abbey; granting charters to bishoprics far away on the Spanish mark; and, on the eastern borders of the empire, erecting Prague as the seat of an archbishopric for the Slavs. The genuineness of the letter to St. Stephen, king of Hungary, to whom he sent a golden crown, and whose kingdom he accepted as a fief of the Holy See, is contested. Gerbert's dreams for the advancement of church and empire were cut short by the death of Otto III., on Feb. 4, 1002, followed a year later by the death of the pope himself, May 12, 1003. He was buried in the church of St. John Lateran.

Besides being the most distinguished statesman, Gerbert was also the most accomplished scholar of his age. His pupil Richer has left us a detailed account of his system of teaching at Reims. So far as the trivium is concerned, his text-books were Victorinus's translation of Porphyry's *Isagoge*, Aristotle's *Categories*, and Cicero's *Topics* with Manlius's *Commentaries*. From dialectics he urged his pupils to the study of rhetoric; but, recognizing the necessity of a large vocabulary, he accustomed them to read Virgil, Statius, Terence, Juvenal, Horace, Persius and Lucan. More remarkable still were his methods of teaching the quadrivium. To assist his lectures on astronomy he constructed elaborate globes of the terrestrial and celestial spheres, on which the course of the planets was marked; for facilitating arithmetical and perhaps geometrical processes he constructed an abacus with 27 divisions and a thousand counters of horn. A younger contemporary speaks of his having made a wonderful clock or sundial at Magdeburg; and we know from his letters that Gerbert was accustomed to exchange his globes for mss. of those classical authors that his own library did not contain. More extraordinary still was his knowledge of music—an accomplishment which seems to have been his earliest recommendation to Otto I. Gerbert's letters contain more than one allusion to organs which he seems to have constructed, and William of Malmesbury has preserved an account of a wonderful musical instrument still to be seen in his days at Reims. The same historian tells us that Gerbert borrowed from the Arabs (Saraceni) the abacus with ciphers. (*See* NUMERALS.) Perhaps Gerbert's chief claim to the remembrance of posterity is to be found in the care and expense with which he gathered together mss. of the classical writers. His love for literature was a passion. In the turmoil of his later life he looked back with regret to his student days, and "for all his troubles philosophy was his only cure." Everywhere—at Rome, at Treves, at Moutier-en-Der, at Gerona in Spain, at Barcelona—he had friends or agents to procure him copies of the great Latin writers for Bobbio or Reims. To the abbot of Tours he writes that he is "labouring assiduously to form a library," and "throughout Italy, Germany and Lorraine (Belgica) is spending vast sums of money in the acquisition of mss." It is noteworthy, however, that Gerbert never writes for a copy of one of the Christian fathers, his aim being, seemingly, to preserve the fragments of a fast-perishing secular Latin literature.

So remarkable a character as that of Gerbert left its mark on the age, and fables soon began to cluster round his name. *See* FAUST. Towards the end of the 11th century Cardinal Benno, the opponent of Hildebrand, is said to have made him the first of a long line of magician popes. William of Malmesbury adds a love adventure at Cordova, a compact with the devil, the story of a speaking statue that foretold Gerbert's death at Jerusalem—a prophecy fulfilled, somewhat as in the case of Henry IV. of England, by his dying in the Jerusalem church of Rome—and that imaginative story of the statue with the legend "Strike here," found its way into the *Gesta Romanorum*.

Gerbert's extant works may be divided into five classes. (*a*) A collection of letters, some 230 in number, contained for the most part in an 11th-century ms. at Leiden. Other important mss. are those of the Barberini Library at Rome (late 16th century), of Middlehill (17th century), and of St. Peter's abbey, Salzburg. With the letters may be grouped the papal decrees of Gerbert when Silvester II. (*b*) The *Acta concilii Remensis ad Sanctum Basolum*, a detailed account of the proceedings and discourses at the great council of St. Basle; a shorter account of his apologetic speeches at the councils of Mouzon and

Causey; and drafts of the decrees of two or three other councils or imperial constitutions promulgated when he was archbishop of Ravenna or pope. The important works on the three above-mentioned councils are to be found in the 11th-century Leiden ms. just alluded to. (*c*) Gerbert's theological works comprise a *Sermo de informatione episcoporum* and a treatise entitled *De corpore et sanguine Domini*, both of very doubtful authenticity. (*d*) Of his philosophical works we only have one, *Libellus de rationali et ratione uti*, written at the request of Otto III. and preserved in an 11th-century ms. at Paris. (*e*) His mathematical works consist of a *Regula de abaco computi*, of which a 12th-century ms. is to be found at the Vatican; and a *Libellus de numerorum divisione* (11th- and 12th-century mss. at Rome, Montpellier and Paris), dedicated to his friend and correspondent Constantine of Fleury. A long treatise on geometry, attributed to Gerbert, is of somewhat doubtful authenticity. To these may be added a very short disquisition on the same subject addressed to Adalbold, and a similar one, on one of his own spheres, addressed to Constantine, abbot of Micy. All the writings of Gerbert are collected in the edition of A. Olleris (Clermont, 1867).

SILVESTER III. When Boniface IX. was driven from Rome early in January 1044, John, bishop of Sabina, was elected in his stead and took the title of Silvester III. Within three months Boniface returned and expelled his rival. Nearly three years later (December 1046) the council of Sutri deprived him of his bishopric and priesthood. He was then sent to a monastery, where he seems to have died.

SILVESTRE DE SACY, ANTOINE ISAAC, Baron (1758–1838), French orientalist, was born in Paris on Sept. 21, 1758. In 1781 he entered the civil service, but he retired in 1792 and lived in seclusion till in 1795 he became professor of Arabic in the newly founded school of living Eastern languages. The interval was in part devoted to the study of the religion of the Druses, which was the subject of his last and unfinished work, the *Exposé de la religion des Druzes* (2 vols., 1838). Since the death of Johann Jakob Reiske, Arabic learning had been in a backward state. In the *Grammaire arabe* (2 vols., 1st ed. 1810, 2nd ed. 1831) and the *Chrestomathie arabe* (3 vols., 1806), together with its supplement, the *Anthologie grammaticale* (1829), De Sacy supplied admirable text-books. In 1806 he became Persian professor. In 1815 he became rector of the university of Paris, and after the second restoration he was active on the commission of public instruction. With Abel Rémusat he was joint founder of the *Société asiatique*, and was inspector of oriental types at the royal printing press. De Sacy, who had been created a peer of France in 1832, died on Feb. 21, 1838.

Among his other works are his edition of Harīrī (1822, 2nd edition by Reinaud, 1847, 1855), with a selected Arabic commentary, and of the *Alfiya* (1833), and his *Calila et Dimna* (1816),—the Arabic version of that famous collection of Buddhist animal tales which has been in various forms one of the most popular books of the world; a version of Abd-Allatif, *Relation arabe sur l'Egypte*, and essays on the history of the law of property in Egypt since the Arab conquest (1805–18). To biblical criticism he contributed a memoir on the Samaritan Arabic of the Pentateuch (*Mém. Acad. des Inscr.* vol. xlix.), and editions of the Arabic and Syriac New Testaments for the British and Foreign Bible Society. Of the brilliant teachers who went out from his lecture-room may be mentioned Professor Heinrich Leberecht Fleischer (1801–88), who contributed elaborate notes and corrections to the *Grammaire arabe* (*Kleinere Schriften*, vol. i., 1885).

SILVESTRINES or **SYLVESTRINES,** an order of monks under the Benedictine rule, founded 1231 by St. Silvester Gozzolini, who in 1231 built a monastery at Montefano. The rule was the Benedictine, but as regards poverty in external things, far stricter than the Benedictine. The order was approved in 1247 by Innocent IV., and at Silvester's death in 1267 there were eleven Silvestrine monasteries. At a later date there were 56, mostly in Umbria, Tuscany and the March of Ancona. In 1907 there were nine Silvestrine houses, one in Rome, and about 60 choir monks.

See Max Heimbucher, *Orden u. Kongregationen* (1907), i. § 30; Wetzer u. Welte, *Kirchenlexicon* (ed. 2); and the *Catholic Encyclopaedia*, art. "Sylvestrines."

SILVICULTURE is the technical branch of forestry (*q.v.*) which is concerned with the establishment and maintenance of the forest. *See* Arboriculture.

SIMALUR, the northernmost island of the chain off the west coast of Sumatra, Dutch East Indies. It is about 54 miles long, and is hilly, the coasts being rocky and reef-bound. Sinabang, on a bay in the south-east, is the capital, and port, where vessels of the Royal Packet Navigation company call, giving connection with Tapa Tuan, on the Sumatran mainland: there is also a cable between Simalur and Singkep, in Achin, Sumatra. Other small places on the coast are Sibigo and Sigule; they are connected by a road. The Banyak islands, nearly 70 in number, lie south-east of Simalur. They are prolific in coco-nut palms and form a port of call, for copra, for vessels of the Royal Packet Navigation company.

SIMANCAS, a town of Spain, in the province of Valladolid; 8 m. S.W. of Valladolid, on the road to Zamora and the right bank of the river Pisuerga. Pop. (1920) 1,032. Simancas is a town of great antiquity, the Roman Septimanca, with a citadel dating from the Moorish occupation in the 9th century. In 934 it was the scene of a battle between the Moors and Christians. The citadel is now the Archivo General del Reino, to which the national archives of Spain were removed by order of Philip II. in 1563. Their transference thither was first suggested to Charles V. by Cardinal Ximenes or Cisneros (d. 1517). The extensive alterations were made by three celebrated 16th-century architects, Juan de Herrera, Alonso Berruguete and Juan Gomez de Mora; the arrangement of the papers was entrusted to Diego de Ayala. They include important private as well as state papers. The archives of the Indies were transferred in 1784 to the Lonja of Seville.

SIMBIRSK: *see* Ulianovsk.

SIMCOE, JOHN GRAVES (1752–1806), British soldier and first lieutenant-governor of Upper Canada, was born at Cotterstock, Northumberland, on Feb. 25, 1752. He entered the army, and first saw active service at Boston in 1775, remaining in America during the greater part of the Revolutionary War. His military career in America ended with the surrender of Cornwallis at Yorktown (Oct. 19, 1781). In 1791 he was appointed lieutenant-governor of the new province of Upper Canada. He reached Kingston, Upper Canada, on July 1, 1792. There the first council was assembled, the government of the new province proclaimed, and the oaths of office taken. Simcoe's ideas of colonial government were dominated by military and aristocratic conceptions quite unsuited to the pioneer conditions of Upper Canada, and there was friction with the colonists and with Lord Dorchester, the governor-general. He left Canada in September 1796. After some service in England he had been designated commander-in-chief for India to succeed Lord Lake, when he died at Exeter on Oct. 26, 1806.

See D. C. Scott, *John Graves Simcoe* (1905).

SIMEON, in the Old Testament, the name of a tribe of Israel, named after the second son of Jacob by Leah (Gen. xxix. 33). According to Gen. xxxiv., the brothers Simeon and Levi massacred the males of Shechem to avenge the violation of their sister Dinah ("judgment") by Shechem the son of Hamor. Jacob disavowed the act, and on his deathbed solemnly cursed their ferocity, condemning the two to be divided in Jacob and scattered in Israel (xlix. 5–7). Subsequently the priestly Levites are found distributed throughout Israel without portion or inheritance (Deut. xviii. 1, Josh. xiii. 14).

On the other hand, Simeon is reckoned among the N. tribes in 2 Chron. xv. 9, xxxiv. 6, but is elsewhere assigned a district in S. Palestine, the cities of which are otherwise ascribed to Judah (*cf.* Josh. xix. 1–9 with xv. 26–32). An interpolation in 1 Chron. iv. 31 states that Judah was their seat in David's time, but there is no support for this in other records (*see* 1 Sam. xxvii., xxx.). In fact, Simeon is not mentioned in the "blessing of Moses" (Deut. xxxiii., *see* S. R. Driver, *Deut.* p. 397 *seq.*), or in the stories of the "judges"; and notwithstanding references to it in the chronicler's history of the monarchy, it is not named in the earlier books of Samuel and Kings. But is Gen. xxxiv. to be taken literally? Shechem is the famous holy city, Hamor a well-known native family, Jacob talks of himself as being "few in number," and the deeds of Simeon and Levi are those of communities, not of individuals. What historical facts are thus represented, and how they are to be brought into line with the early history of Israel, are problems which have defied solution (*see* J. Skinner, *Genesis*, p. 421 *seq.*).

It is conjectured that Dinah represents a clan or group (*cf.* DAN) which settled in Shechem and was exposed to danger (*e.g.*, oppression or absorption); the tribes Simeon and Levi intervened on its behalf, the ensuing massacre was avenged by the Canaanites, and the two were broken up. These events are supposed to belong to an early stage in the invasion of Palestine by the Israelites (15th–13th century B.C.), perhaps to a preliminary settlement by the "sons" of Leah (Reuben, Simeon, Levi and Judah), previous to the entrance of the "son" of Rachel, Joseph, the "father" of Ephraim and Manasseh.

In the New Testament, (1) the seer who recognized the infant Jesus as the Redeemer; (2) an alternate form of Simon.

SIMEON (or SYMEON) **OF DURHAM** (d. after 1129), English chronicler, embraced the monastic life before the year 1083 in the monastery of Jarrow; but only made his profession at a later date, after he had removed with the rest of his community to Durham. He composed his *Historia ecclesiae Dunelmensis,* extending to the year 1096, at some date between 1104 and 1108. The original manuscript is at Durham in the library of Bishop Cosin. There are two continuations, both anonymous. The first carries the history from 1096 to the death of Ranulf Flambard (1129); the second extends from 1133 to 1144. A Cambridge ms. contains a third continuation covering the years 1141–1154. About 1129 Simeon undertook to write a *Historia regum Anglorum et Dacorum.* This begins at the point where the *Ecclesiastical History of Bede* ends. The section dealing with the years 1119–1129 is, however, an independent and practically contemporaneous narrative.

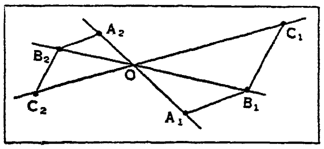
The most complete modern edition of his works is that of Thomas Arnold ("Rolls" series, 2 vols., 1882–1885). Simeon's works have been translated by J. Stevenson in his *Church Historians of England,* vol. iii. part ii. (1855).

SIMEON STYLITES, ST. (390–459), the first and most famous of the Pillar-hermits (Gr. στῦλος, pillar), was born in N. Syria. After having been expelled from a monastery for his excessive austerities, at thirty years of age he built a pillar six feet high on which he took up his abode. He made new pillars higher and higher, till after ten years he reached the height of sixty feet. On this pillar he lived for thirty years without ever descending. A railing ran round the capital of the pillar, and a ladder enabled his disciples to take him the necessaries of life. From his pillar he preached and exercised a great influence, converting numbers of heathen and taking part in ecclesiastical politics. The facts would seem incredible were they not vouched for by Theodoret, who knew him personally (*Historia religiosa,* c. 26). Moreover, Simeon had many imitators, well authenticated pillar-hermits being met with till the 16th century.

The standard work on the subject is *Les Stylites* (1895), by H. Delehaye, the Bollandist; for a summary *see* the article "Säulenheilige," in Herzog's *Realencyklopädie* (ed. 3). On Simeon *see* Th. Nöldeke's *Sketches from Eastern History* (1892), p. 210, the *Dictionary of Christian Biography* and *The Catholic Encyclopaedia.*

SIMFEROPOL, the administrative centre of the Crimean A.S.S.R., situated on the northern slopes of the Chatyr-dagh mountains in 44° 58′ N., 34° 3′ E. on the Salgar river. Simferopol grew rapidly after the railway linking it with the main Russian net was constructed. Pop. (1926) 80,719. The small fortress of Napoli erected by the ruler of Taurida about 100 B.C. existed near the town until the end of the 3rd century. Later it was a Tatar settlement Ak-mechet (Sultan Serai) the residence of the chief military commander of the khan. It was captured and burnt by the Russians in 1736. After the conquest of the Crimea by the Russians in 1784, it received its present name.

SIMILAR FIGURES. Geometric figures are said to be *similar* if they have the same shape but not necessarily the same size; *e.g.*, any two squares are similar; if they are of the same size, they are *congruent,* or *identically equal,* but they are still similar. Any two circles are similar, but not any two ellipses, for ellipses may have different shapes (*see* ELLIPSE). Solids may also be similar, as in the case of cubes or of spheres. Similarity of figures is the basis of trigonometry (*q.v.*) and of indirect measures in general. Speaking more precisely, two systems of points, $A_1, B_1, C_1, \cdots$ and $A_2, B_2, C_2, \cdots$ are said to be similar when they can be so placed that all lines A_1A_2, B_1B_2, $C_1C_2, \cdots$, joining corresponding points form a pencil whose vertex, O, divides each line into segments having a constant ratio r. In the figure here shown, the constant ratio is 2/3. Two figures are said to be similar when their systems of points are similar. The point O is called the *centre of similitude.* If $r=1$, the figures are said to be *symmetric with respect to the centre O* (*see* SYMMETRY).



SIMILAR FIGURES

SIMLA, a town and district in British India, in the Punjab. The town is the summer residence of the viceroy and staff of the supreme government, and also of the Punjab government. It is 58 m. by cart-road from the railway station of Kalka. A metre-gauge railway, 68 m. long, was opened from Kalka to Simla in 1903. The population in 1921 was 27,494, but that was only the winter population. The sanatorium of Simla occupies a spur of the lower Himalaya, running east and west for about 6 m. The ridge culminates at the east in the eminence of Jakko, in the vicinity of which bungalows are most numerous; the viceregal lodge stands on Observatory Hill. The east of the station is known as Chota Simla and the west as Boileauganj. The situation is one of great beauty; and the houses, built separately, lie at elevations between 6,600 and 8,000 ft. above sea-level. To the north, a beautiful wooded spur, branching from the main ridge, is known as Elysium. Three miles west is the cantonment of Jutogh. The minor sanatoria of Kasauli, Sabathu, Dagshai and Solon lie some distance to the south. The first European house at Simla was built in 1819, and the place was first visited by a governor-general in 1827. It has gradually become the permanent headquarters of many of the official establishments. The two chief medical institutions are the Ripon and Walker hospitals.

The DISTRICT OF SIMLA has an area of 101 sq.m., and had a population in 1921 of 45,327. The mountains of Simla and the surrounding states compose the southern outliers of the great central chain of the East Himalaya. Throughout all the hills forests of deodar abound, while rhododendrons clothe the slopes up to the limit of perpetual snow. The principal rivers are the Sutlej, Pabar, Giri, Gambhar and Sarsa.

The acquisition of the patches of territory forming the district dates from various times subsequent to the close of the Gurkha War in 1816. The Simla Hill States—which as now constituted number 27 in all—include Jubbal, Bashahr, Keonthal, Baghal and Hindur. The States of Sirmor (Nahan) and Bilaspur are under the direct control of the Government of India.

SIMMEL, GEORG (1858–1918), German philosopher and sociologist, was born in Berlin on March 1, 1858. Professor of philosophy first in Berlin (1901), then in Strasbourg (1914), Simmel was one of the first academic philosophers to apply philosophy to history and sociology. His philosophy centres round the conception of a spiritual life, various in its forms, and obedient to its own laws, whose external manifestations are to be seen in sociology and the arts. The ultimate theme of his works, which are written in a brilliant and very personal style, is nearly always the connection between life and the metaphysical general principles, revealed to the philosopher in concrete existence. He died in Strasbourg on Sept. 28, 1918.

Simmel's chief works are: *Über Sociale Differenzierung* (1890); *Einleitung in die Moralwissenschaft* (1892–93); *Philosophie des Geldes* (1900); *Kant* (1904); *Die Probleme der Geschichtsphilosophie,* 2nd ed. (1905); *Schopenhauer und Nietzsche* (1907); *Die Religion* (1907); *Philosophische Kultur* (1911); *Rembrandt* (1917); *Grundfragen der Soziologie* (1917); *Lebensanschauung* (1918). *See* W. Knevels, *Simmels Religionstheorie* (1920); N. J. Spykman, *The Social Theory of G. Simmel* (1925).

SIMMONS, EDWARD EMERSON (1852–), American artist, was born at Concord, Mass., on Oct. 27, 1852. He graduated from Harvard college in 1874, and was a pupil of Lefebvre and Boulanger in Paris, where he took a gold medal. He was awarded the prize by the Municipal Art Society of New York for a mural decorative scheme, which he carried out for the criminal courts building, later decorating the Waldorf-Astoria

hotel in New York, the library of Congress, Washington, and the capitol at St. Paul, Minn., and many other public and private buildings. He was elected to the National Institute of Arts and Letters and was one of the original members of the Ten American Painters.

SIMMS, WILLIAM GILMORE (1806–1870), American poet, novelist, dramatist and historian, was born at Charleston, S. C., April 17, 1806. His mother died in his infancy; his father, having failed in business, embarked on a series of wanderings on the border, fighting Indians and finally settling on a plantation in Mississippi. To the father's tales of wild adventure and the son's observation of frontier types on a visit to the West must be attributed some of the best features of Simms's border romances. In general, however, his life and work were shaped by the fact that he made his home in Charleston, where his grandmother had reared him. First an apprentice to a druggist, then a lawyer and an editor, largely self-educated, he received little recognition from the aristocrats of that city, in spite of his lifelong devotion to the literature of the South. He gave advice and financial help to the literary aspirants who besieged him; he contributed with little or no remuneration reams of material to the feeble southern papers and magazines, six of which he founded and conducted; but he was compelled to go to the North, where he sold the serial and book rights of most of his tales, to obtain the money and fame his own city denied him. He served in the South Carolina legislature, but lost by one vote the post of lieutenant governor. His later life was shadowed by poverty, by the burning of his home and library during the Civil War, by the defeat of the secessionist cause which he had supported and by the death of his second wife and several beloved children. Nevertheless, he remained a gallant figure, writing unceasingly until the break-down that came before his death at Charleston June 11, 1870.

Of his literary output Simms's novels are most important, ranking him next to Cooper in the depiction of frontier life. His novel of the Indians, *The Yemassee* (1835); his Revolutionary series, including *The Partisan* (1835), *Mellichampe* (1836), *Katherine Walton* (1851), *The Sword and the Distaff* (1852; published later as *Woodcraft*), *The Forayers* (1855), and *Eutaw* (1856); and his tale of the outlaws of the West, *Border Beagles* (1840), are particularly to be commended. *Beauchampe* (1842) and *Charlemont* (1856), both based on a famous Kentucky murder used by Poe and other writers, are also of interest.

As a novelist Simms's greatest weaknesses were his carelessness in technique, due to hasty composition, and his excessive use of the horrible; his chief sources of strength were his inventiveness, his vivid descriptive powers, and his bold characterization of eccentric border types. He prepared the materials for his historical romances with the care of an antiquarian and he realized the value of fiction for social history—a fact that is brought out in the best of his collections of short stories, *The Wigwam and the Cabin* (1845–46; published in Aberdeen as *Life in America*, 1858). His poems, largely of a sentimental, dreamy type, were published in two volumes in 1853, after being issued in various minor compilations. Simms's scholastic deficiencies, which he himself felt keenly, prevented his *Supplement to the Plays of William Shakespeare* (1848) from being of value save as a revelation of his tastes. His *History of South Carolina* (1840; many times republished, and still used in the public schools of the State), his other works devoted to South Carolina, and his edition of the *War Poetry of the South* (1867) reveal his loyalty to his section. Of his biographies the best probably are the lives of the Chevalier Bayard (1847) and Captain John Smith (1846), although the *Life of Francis Marion* (1844) appeared in the greatest number of editions. A revised edition of his more important works appeared in ten volumes in 1882.

W. P. Trent's *William Gilmore Simms* (1892) is an admirable biography. *See* also O. Wegelin's *List of the Separate Writings of William Gilmore Simms* (1906) and John Erskine's *Leading American Novelists* (1910).

SIMNEL, LAMBERT (fl. 1477–1534), English impostor, was probably the son of a tradesman at Oxford. He was about ten years old in 1487, and was described as a handsome youth of intelligence and good manners. In 1486, the year following the accession of Henry VII., rumours were spread by the Yorkists that the two sons of Edward IV., who had been murdered in the Tower of London, were still alive. A young Oxford priest, Richard Symonds by name, decided to put forward the boy Simnel as one of these princes. He provided him with a suitable education, but meanwhile a report having gained currency that the young earl of Warwick, son of Edward IV.'s brother George, duke of Clarence, had died in the Tower, Symonds decided that the impersonation of Warwick would be more effective. The Yorkists had many adherents in Ireland, and thither Lambert Simnel was taken by Symonds early in 1487. He gained the support of the earl of Kildare, the archbishop of Dublin, the lord chancellor and a powerful following, and was crowned as King Edward VI. in the cathedral in Dublin on May 24, 1487. Messages asking for help were sent to Margaret, duchess of Burgundy, sister of Edward IV., to Sir Thomas Broughton and other Yorkist leaders.

On Feb. 2, 1487 Henry VII. held a council at Sheen to concert measures for dealing with the conspiracy. Elizabeth Woodville, widow of Edward IV., was imprisoned in the convent of Bermondsey; and the real earl of Warwick was shown in public in the streets of London. John de la Pole, earl of Lincoln, himself a nephew of Edward IV., had probably connived at the Simnel impersonation. He now fled to Flanders, where he joined Lord Lovell, who had headed an unsuccessful Yorkist rising in 1486, and in May 1487 the two lords proceeded to Dublin, where they landed a few days before the coronation of Lambert Simnel. They were accompanied by 2,000 German soldiers under Martin Schwartz, procured by Margaret of Burgundy to support the enterprise, Margaret having recognized Simnel as her nephew. This force, together with some ill-armed Irish levies commanded by Sir Thomas Fitzgerald, landed in Lancashire on June 4. King Henry immediately marched to Nottingham, where his army was strengthened by the addition of 6,000 men. Making for the fortress of Newark, Lincoln and Sir Thomas Broughton, accompanied by Simnel, attacked the royal army near Stoke-on-Trent on June 16, 1487. After a fierce and stubborn struggle the Royalists were completely victorious, though they left 2,000 men on the field; Lincoln, Schwartz and Fitzgerald with 4,000 of their followers were killed, and Lovell and Broughton disappeared. The priest Symonds and Simnel were taken prisoners. Henry VII., recognizing that Lambert Simnel had been a tool in Yorkist hands, took him into his own service as a scullion. He was later promoted to be royal falconer, and is said to have afterwards become a servant in the household of Sir Thomas Lovell. He was still living in the year 1534.

See Bacon, *History of Henry VII.*, with notes by J. R. Lumby (1881); Bagwell, *Ireland under the Tudors* (3 vols., 1885–1890); James Gairdner, *Henry VII.* (London, 1889) and *Letters and Papers illustrative of the reigns of Richard III. and Henry VII.* ("Rolls" series, 2 vols., London, 1861–1863); *The Political History of England*, vol. v., by H. A. L. Fisher (London, 1906); and W. Busch, *England under the Tudors* (1895). For a contemporary account *see* Polydore Vergil, *Anglicae historiae*, to which all the later narratives are indebted.

SIMOCATTA[1], **THEOPHYLACT**, Byzantine historian, a native of Egypt, held an official position at Constantinople during the reign of Heraclius (610–640). He is best known as the author of a history, in eight books, of the reign of the emperor Maurice (582–602), for which period he is the best and oldest authority. The work describes the wars with the Persians, the Avars and Slavs, and the emperor's tragic end (ed. pr. by J. Pontanus, 1609; best edition by C. de Boor, 1887, with a valuable Index Graecitatis). "His want of judgment renders him diffuse in trifles and concise in the most interesting facts" (Gibbon), but his general trustworthiness is admitted. The history contains an introduction in the form of a dialogue between History and Philosophy.

Simocatta was also the author of *Physical Problems*, a work on natural history (ed. J. Ideler in *Physici et medici Graeci minores*, i. 1841); and of a collection of 85 essays in epistolatory form. The best edition is by R. Hercher in *Epistolographi Graeci* (1873). The letters were translated into Latin (1509) by Copernicus (reprinted 1873 by F. Hipler in *Spicilegium Copernicanum*).

See C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

SIMON, SIR JOHN (1816–1904), English surgeon and sanitary reformer, was born in London on Oct. 10, 1816. In the spring of 1844 he gained the first Astley Cooper prize by a physiological essay on the thymus gland, and the following year was elected F.R.S. Simon published many clinical surgical lectures of the greatest importance, and contributed an article on "In-

[1]Other forms of the name are Simocattos, Simocatos, Simocates.

flammation" to Holmes's *System of Surgery* which has become a classic of its kind. It was, however, on his appointment in 1848 as medical officer of health to the City of London, and afterwards to the Government, that his great abilities in sanitary science found full scope. Simon can claim priority over Cock in the operation of perineal puncture of the urethra in cases of retention from stricture. He died on July 23, 1904.

SIMON, SIR JOHN ALLSEBROOK (1873–), British politician and lawyer, the son of a Congregational minister, was born Feb. 28, 1873, at Bath, and educated at Fettes College, Edinburgh, and Wadham College, Oxford, where he was a scholar. He became president of the Union in 1896, and was subsequently elected fellow of All Souls. He went to the Bar, became Barstow Law scholar in 1898, and was called in 1899. His manifest abilities and the persuasiveness of his advocacy soon brought him to notice; he was chosen one of the counsel for the British Govt. in the arbitration on the Alaska Boundary in 1903; and he rapidly attained so considerable a practice that he was able to take silk in 1908. He had gone into politics, and was elected Liberal member for Walthamstow at the general election of 1906. At first, probably owing to his absorption in his legal work, he did not command nearly so much attention in Parliament as his Wadham contemporary and fellow-lawyer, F. E. Smith (afterwards Lord Birkenhead). But he gradually made his way, and was appointed by Asquith Solicitor-General in 1910, was knighted the same year, and became Attorney-General with a seat in the Cabinet in 1913.

On the outbreak of the war in 1914, his resignation, along with those of Lord Morley and Burns, was expected; but he finally decided to remain with his chief and the bulk of his colleagues. When the first war Coalition Government was formed, in May 1915, he was offered the lord chancellorship, but he declined the greatest prize of his profession as he preferred a political career in the Commons. Accordingly he accepted the home secretaryship, and gave up his legal practice. Early, however, in the following year, owing to his inability to accept the Government bill for compulsory military service, he resigned his office and led a fruitless opposition to the measure in the House; and then went out to the front in France as a major in the R.A.F. He subsequently resumed practice as a barrister, and immediately regained his position in the front rank of his profession. On the break between Asquith and Lloyd George in 1916, John Simon adhered to the former. He lost his seat in Parliament at the general election in Dec. 1918, but was returned for Spen Valley in 1922. On the occasion of the general strike in May 1926 John Simon argued in Parliament that the strike was not covered by the Trade Disputes Act. His speech created a deep impression. In January 1928, on appointment as chairman of the Indian Statutory Commission (*see* INDIA: *History*) Simon retired. He was made G.C.S.I. in the Birthday Honours, 1930.

SIMON, JULES FRANÇOIS (1814–1896), French statesman and philosopher, was born at Lorient on Dec. 27, 1814. His father was a linen-draper from Lorraine, who abjured Protestantism before his second marriage (of which Jules Simon was the son) with a Catholic Breton. The family name was Suisse, which Simon dropped in favour of his third prenomen. At the École Normale in Paris he came in contact with Victor Cousin, who sent him to Caen and then to Versailles to teach philosophy. He helped Cousin, without receiving any recognition, in his translations from Plato, and in 1839 became his deputy in the chair of philosophy at the Sorbonne, with the meagre salary of 83 francs per month. He also lectured on the history of philosophy at the École Normale. At this period he edited the works of Malebranche (2 vols., 1842), of Descartes (1842), Bossuet (1842) and of Arnauld (1843), and in 1844–1845 appeared the two volumes of his *Histoire de l'école d'Alexandrie.* He became a regular contributor to the *Revue des deux mondes,* and in 1847, with Amédée Jacques and Émile Saisset, founded the *Liberté de penser,* with the intention of throwing off the yoke of Cousin, but he retired when Jacques allowed the insertion of an article advocating the principles of collectivism. In 1848 he represented the Côtes-du-Nord in the National Assembly, and in 1849 entered the Council of State, but was retired on account of his republican opinions. After the *coup d'état,* which was followed by his dismissal from his professorship, he used his leisure in writing *Le Devoir* (1853), which was translated into modern Greek and Swedish, *La Religion naturelle* (1856, Eng. trans., 1887), *La Liberté de conscience* (1857), *La Liberté politique* (1859), *La Liberté civile* (1859), *L'Ouvrière* (1861), *L'École* (1864), *Le Travail* (1866), *L'Ouvrier de huit ans* (1867) and others. In 1863 he was returned to the Corps Législatif for the 8th *circonscription* of the Seine, and supported "les Cinq" in their opposition to the government.

He became minister of instruction in the government of National Defence on Sept. 5, 1870. After the capitulation of Paris in January 1871 he was sent down to Bordeaux to prevent the resistance of Gambetta to the peace. But at Bordeaux Gambetta, who had issued a proclamation excluding from the elections officials under the Empire, was all powerful. He affected to dispute Jules Simon's credentials, and issued orders for his arrest. Meanwhile Simon had found means of communication with Paris, and on Feb. 6, was reinforced by Eugène Pelletan, E. Arago and Garnier-Pagès. Gambetta resigned, and the ministry of the Interior, though nominally given to Arago to avoid the appearance of a personal issue, was really in Simon's hands. Defeated in the department of the Seine, he sat for the Marne in the National Assembly, and resumed the portfolio of education in the first cabinet of M. Thiers's presidency. He retained office until a week before the fall of Thiers in 1873.

Simon was regarded by the monarchical Right as one of the most dangerous obstacles in the way of a restoration, which he did as much as any man (except perhaps the comte de Chambord himself) to prevent, but by the extreme Left he was distrusted for his moderate views, and Gambetta never forgave his victory at Bordeaux. In 1875 he became a member of the French Academy and a life senator, and in 1876, on the resignation of M. Dufaure, was summoned to form a cabinet. He replaced antirepublican functionaries in the civil service by republicans, and held his own until May 3, 1877, when he adopted a motion carried by a large majority in the Chamber inviting the cabinet to use all means for the repression of clerical agitation. Marshal MacMahon then practically demanded his resignation. This act of the president, known as the "Seize Mai," drove him finally from office. He justified his action in submitting instead of appealing to the Chamber by his fear of providing an opportunity for a *coup d'état* on the part of the marshal.

The rejection (1880) of article 7 of Ferry's Education Act, by which the profession of teaching would have been forbidden to members of non-authorized congregations, was due to Simon's intervention. He was in fact the chief of the Left Centre opposed to the radicalism of Jules Grévy and Gambetta. He was director of the *Gaulois* from 1879 to 1881, and his influence in the country among moderate republicans was retained by his articles in the *Matin* from 1882 onwards, in the *Journal des Débats,* which he joined in 1886, and in the *Temps* from 1890.

He left accounts of some of the events in which he had participated in *Souvenirs du 4 septembre* (1874), *Le Gouvernement de M. Thiers* (2 vols., 1878), in *Mémoires des autres* (1889), *Nouveaux mémoires des autres* (1891) and *Les Derniers mémoires des autres* (1897), while his sketch of *Victor Cousin* (1887) was a further contribution to contemporary history. For his personal history the *Premiers mémoires* (1900) and *Le Soir de ma journée* (1902), edited by his son Gustave Simon, may be supplemented by Léon Séché's *Figures bretonnes, Jules Simon, sa vie, son oeuvre* (new ed., 1898), and G. Picot, *Jules Simon: notice historique* . . . (1897); also by many references to periodical literature and collected essays in Hugo P. Thieme's *Guide bibliographique de la litt. franç. de 1800 à 1906* (1907).

SIMON, RICHARD (1638–1712), French biblical critic, born at Dieppe on May 13, 1638, was educated by the Fathers of the Oratory at Dieppe and at the university of Paris. Simon entered the priesthood in 1670, and the same year wrote a pamphlet in defence of the Jews of Metz, who had been accused of having murdered a Christian child. About this time began his controversies with the Port Royalists and with the Benedictines, and his enemies sought to drive him from Paris. He was engaged at the time in superintending the printing of his *Histoire critique du Vieux Testament,* which was to be dedicated to Louis XIV.

The proof sheets were held up pending the return of the king from Flanders, and fell into the hands of the Port Royalists, who had in hand a translation into French of the Prolegomena to *Walton's Polyglott*. Simon now announced his intention of publishing an annotated edition of the Prolegomena, and actually added to the *Critical History* a translation of the last four chapters of that work, which had formed no part of his original plan. Simon's announcement prevented the appearance of the projected translation, but his enemies found the desired opportunity in the alleged heterodoxy of some of the views expressed by Simon. A decree of the council of state was obtained, and the whole impression, consisting of 1,300 copies, was seized by the police and destroyed. Simon was expelled by the Oratorians from their fellowship, and retired in 1679 to his curacy of Bolleville, Normandy. Finally the *Critical History* appeared, with Simon's name on the title page, in the year 1685, from the press of Reenier Leers in Rotterdam. Simon died at Dieppe on April 11, 1712.

The remaining works of Simon were: *Histoire critique du texte du Nouveau Testament* (1689), *Histoire critique des versions du Nouveau Testament* (1690); *Histoire critique des principaux commentateurs du Nouveau Testament* (1693), and his *Nouvelles Observations sur le texte et les versions du Nouveau Testament* (1695).

The principal authorities for the life of Simon are the life or "éloge" by his grand-nephew De la Martinière in vol. i. of the *Lettres choisies* (4 vols., 1730); *Richard Simon et son Vieux Testament*, by A. Bernus (Lausanne,, 1869); H. Margival, *Essai sur Richard Simon et la critique biblique au XVIIe siècle* (1900). For the bibliography, *see*, in addition to the various editions of Simon's works, A. Bernus, *Notice bibliographique sur Richard Simon* (Basel, 1882).

SIMON, THOMAS (*c.* 1623–1665), English medallist, was born, according to Vertue, in Yorkshire about 1623. He studied engraving under Nicholas Briot, and about 1635 received a post in connection with the mint. In 1645 he was appointed by the parliament joint chief engraver along with Edward Wade, and, having executed the great seal of the Commonwealth and dies for the coinage, he was promoted to be chief engraver to the mint and seals. He produced several fine portrait medals of Cromwell, one of which is copied from a miniature by Cooper. After the Restoration he was appointed engraver of the king's seals. On the occasion of his contest with the brothers Roettiers, who were employed by the mint in 1662, Simon produced his celebrated crown of Charles II., on the margin of which he engraved a petition to the king. This is usually considered his masterpiece. He is believed to have died of the plague in London in 1665.

A volume of *The Medals, Coins, Great Seals and other Works of Thomas Simon, engraved and described by George Vertue*, was published in 1753.

SIMON BEN YOHAI (2nd century A.D.), a Galilean Rabbi, one of the most eminent disciples of Aqiba (*q.v.*). His master was executed by Hadrian, and Simon's anti-Roman sentiments led to his own condemnation by Varus *c.* A.D. 161 (according to Graetz). He escaped this doom and dwelt for some years in a cavern. Emerging from concealment, Simon settled in Tiberias and in other Galilean cities. He acquired a reputation as a worker of miracles, and on this ground was sent to Rome as an envoy. To Simon were attributed the important legal homilies called *Sifre* and *Mekhilta* (*see* MIDRASH), and above all the *Zohar*, the Bible of the Kabbalah (*q.v.*). This latter ascription is altogether unfounded, the real author being Leon, Moses de (*q.v.*).

The fullest account of Simon's teachings is to be found in W. Bacher's *Agada der Tannaiten*, ii. pp. 70–149.

SIMONDS, FRANK HERBERT (1878–), American writer, was born in Concord, Massachusetts, April 5 1878. He graduated from Harvard University in 1900, after having seen active service in the war with Spain. He became a reporter on the New York *Tribune* in 1901, and was with the Washington bureau of that paper in 1903, and its Albany correspondent in 1904–05. He was Albany correspondent for the New York *Evening Post* in 1906–08, became an editorial writer for the *Sun* in 1908, was editor of the New York *Evening Sun* in 1913–14, and from 1915 to 1918 was associate editor of the New York *Tribune*. During the World War his brilliant articles in the American *Review of Reviews*, analysing the military and political situation from month to month, brought him a wide reputation. After the Armistice he continued to contribute articles on international politics to this review (of which he became foreign editor in 1914), to other periodicals, and to a newspaper syndicate. His books include *They Shall Not Pass* (1916), an account of Verdun; *History of the World War* (1917–20); and *How Europe Made Peace without America* (1927).

SIMONIDES (or SEMONIDES) **OF AMORGOS,** Greek iambic poet, flourished in the middle of the 7th century B.C. He was a native of Samos, and derived his surname from having founded a colony in the neighbouring island of Amorgos. According to Suïdas, besides two books of iambics, he wrote elegies, one of them a poem on the early history of the Samians. The elegy included in the fragments (85) of Simonides of Ceos is more probably by Simonides of Amorgos. We possess about thirty fragments of his iambic poems, written in clear and vigorous Ionic, satiric in type, but less personal than Archilochus. His largest fragment is an elaborate comparison of various types of women with various animals.

See Fragments in T. Bergk, *Poëtae lyrici Graeci;* separate editions by F. T. Welcker (1835), and especially by P. Malusa (1900), with exhaustive introduction, bibliography and commentary.

SIMONIDES OF CEOS (*c.* 556–469 B.C.), Greek lyric poet, was born at Iulis in the island of Ceos. During his youth he taught poetry and music in his native island, and composed paeans for the festivals of Apollo. Later he went to live at Athens, at the court of Hipparchus, the patron of literature. After the murder of Hipparchus (514), Simonides withdrew to Thessaly, where he enjoyed the patronage of the Scopadae and Aleuadae (two celebrated Thessalian families). Apparently some disaster overtook the Scopadae, which resulted in the extinction of the family. After the battle of Marathon Simonides returned to Athens, but soon left for Sicily at the invitation of Hieron, at whose court he spent the rest of his life.

His reputation as a man of learning is shown by the tradition that he introduced the distinction between the long and short vowels (ε, η, ο, ω), afterwards adopted in the Ionic alphabet which came into general use during the archonship of Eucleides (403). He was also the inventor of a system of mnemonics (Quintilian xi. 2, 11). So unbounded was his popularity that he was a power even in the political world; we are told that he reconciled Theron and Hieron on the eve of a battle between their opposing armies. He was the intimate friend of Themistocles and Pausanias the Spartan, and his poems on the war of liberation against Persia no doubt gave a powerful impulse to the national patriotism. For his poems he could command almost any price: later writers, from Aristophanes onwards, accuse him of avarice, probably not without some reason.

Of his poetry we possess two or three short elegies (Fr. 85 seems from its style and versification to belong to Simonides of Amorgos, or at least not to be the work of our poet), several epigrams and about ninety fragments of lyric poetry. The epigrams written in the usual dialect of elegy, Ionic with an epic colouring, were intended partly for public and partly for private monuments. There is strength and sublimity in the former, with a simplicity that is almost statuesque, and a complete mastery over the rhythm and forms of elegiac expression. Those on the heroes of Marathon and Thermopylae are the most celebrated. In the private epigrams there is more warmth of colour and feeling, but few of them rest on any better authority than that of the Palatine anthology. One interesting and undoubtedly genuine epigram of this class is upon Archedice, the daughter of Hippias the Peisistratid, who, "albeit her father and husband and brother and children were all princes, was not lifted up in soul to pride." The lyric fragments vary much in character and length: one is from a poem on Artemisium, celebrating those who fell at Thermopylae, with which he gained the victory over Aeschylus; another is an ode in honour of Scopas (commented on in Plato, *Protagoras*, 339 b); the rest are from odes on victors in the games, hyporchemes, dirges, hymns to the gods and other varieties. The poem on Thermopylae breathes a lofty national pride; the others are full of pathos and feeling, combined with a genial

worldliness. "It is hard," he says (Fr. 5), "to become a truly good man, perfect as a square in hands and feet and mind, fashioned without blame. Whosoever is bad, and not too wicked, knowing justice, the benefactor of cities, is a sound man. I for one will find no fault with him, for the race of fools is infinite." His most celebrated fragment is a dirge, in which Danaë, adrift with the infant Perseus on the sea in a dark and stormy night, takes comfort from the peaceful slumber of her babe. Simonides here illustrates his own saying that "poetry is vocal painting, as painting is silent poetry."

Of the many English translations of this poem, one of the best is that by J. A. Symonds in *Studies on the Greek Poets.* Fragments in T. Bergk, *Poëtae lyrici Graeci;* standard edition by F. G. Schneidewin (1835) and of the *Danaë* alone by H. L. Ahrens (1853). Other authorities are given in the exhaustive treatise of E. Cesati, *Simonide di Ceo* (1882); *see* also W. Schröter, *De Simonidis Cei melici sermone* (1906).

SIMON MAGUS. One of the most ancient and interesting rivals of early Gentile Christianity was the sect of the Simonians. Its founder was a skilful magician who had established himself in the city of Samaria just prior to its evangelization and had captivated the populace by his sorcery, so that he was generally known as "the power of God which is called great." His ascendancy was broken by the arrival in Samaria of Philip (Acts 8.5; the interpretation of this story depends somewhat on the view taken of the sources of Acts), whose novel cures and teaching attracted many converts to Christianity and ultimately won over Simon himself who was baptized with the rest. It is probable that Simon's conversion was due less to a change of heart than to a misunderstanding that baptism and the apostle's cures were evidence of a magic superior to his own, the art of which he might hope to acquire as Philip's disciple. Proof that he had carried over the mentality of his old profession into his new religion was not slow in forthcoming. When Philip was reinforced by Peter and John who supplemented baptism by the gift of the Spirit through the laying on of hands, Simon asked that he might be taught to perform this rite and to obtain power to dispense the Holy Spirit and he offered the Apostles a fee for their instruction. Peter, perceiving how slight an impression Christianity had made upon the magician's mind, rebuked him severely and pointed out that, as he had no right understanding of Christianity, he could not share in its benefits. Simon accepted the reproof and begged Peter to pray for his forgiveness.

We hear no more of Simon in Acts and might have assumed that his repentance was enduring and that he had been absorbed into the mass of Samarian Christians, if we did not have later references to him and fragments of a sectarian literature in which he figures as a god and which show that he must have withdrawn from Christianity and initiated a movement of his own in which Christian and Pagan elements were freely and curiously combined. From these later sources (Justin Martyr, Irenaeus, Epiphanius and Hippolytus), it appears that Simon's birthplace was Gitta, that he journeyed to Rome where he had some success in gaining followers under Claudius, that he was generally accompanied by a Phoenician woman named Helen, who had formerly been a prostitute but whom he associated with his own claims for divine honours, that he had a number of disciples of whom the most important were Menander and Saturninus and that he met his end through a foolish attempt to reproduce the resurrection of Jesus by allowing himself to be buried alive in the mistaken supposition that he would be able to rise again on the third day. Justin has a story that a statue was set up in Simon's honour on the Tiber with the inscription, *Simoni Deo Sancto,* but this is probably an error, as a statue answering to Justin's description and inscribed, *Semoni Sancto Deo Fidio Sacrum Sex Pompeius, S.P. F. Col. Mussianus Quinqennalis Decur Bidentalis Donum Dedit,* was unearthed on the Tiber in modern times. Semo was a local, perhaps Sabine, deity and had nothing to do with Simon, but the mistake was not an impossible one for Justin or his source to have made.

On the development of Simonian theology we are better informed than on the external history of the sect. Just what was implied in the view, current in Samaria in Simon's pre-Christian days, that he was "the power of God which is called great" is obscure and it is only a possibility that the god whose power he was thought to be was Jehovah. Evidence that he was influenced by Judaism apart from Christianity is wholly lacking. The recurrence of the phrase, "power of God," or its equivalent, in all the later accounts suggests a certain continuity and it seems probable that, even before his conversion, he advanced a theology similar to that described by Irenaeus (*Adv. haer.* 1.16.1 Harvey) but lacking the elements borrowed later from Christianity and that after his withdrawal from the church he revised this system into a parallel and rival of Christianity.

Apart from Justin's meagre statement that Simon was worshipped as the supreme God and Helen regarded as the "primary notion" emanating from him, our first satisfactory account of Simonian theology is given by Irenaeus, whose assumption that he is describing Simon's own teaching is erroneous, for he is evidently drawing from a later source in which reflections from contemporary christological speculation are unmistakable. In this system Simon is identified with the supreme God, the Father and most exalted Power from whom, before the creation of the world, a female principle emanated. This principle was his first notion through whom it occurred to him to create angels and archangels. Knowing the Father's mind, she issued from him to execute his will and made the angels and powers who, in turn, fashioned the visible world. These inferior beings were ignorant of the Father's existence but were jealous of their mother and, unwilling to be thought the offspring of another, detained her on the earth and forced her through a series of degrading incarnations. She appears in history as Helen of Troy and later as Simon's companion, Helen of Tyre, whom he came to save and who, in Simonian exegesis, is identical with the lost sheep of the parable. To rescue her and to bring salvation to men the supreme Power became incarnate and descended to earth where the angels were quarrelling for ascendancy. He came in human form, though in fact he was no man, and played the Passion in Judaea, though his sufferings were only apparent. He appears among the Jews as the Son, but also descended in Samaria as the Father and among the Gentiles as the Holy Spirit. The advent of this hitherto unknown god abrogated the precepts of the Prophets whose utterances had been inspired by the angels and designed to enslave man and obscure the truth that salvation comes not through good works but through the grace of Simon and hope in Helen and him.

The interesting features in this otherwise rather commonplace myth are the curiously Sabellian-like Trinitarian doctrine, the Iocetic theory of incarnation, and the doctrine of justification by faith or rather by hope—all of which appear to have been transferred bodily from Christianity and adapted to Simon's theology. The meaning of the Father's appearance in Samaria is obscure, but may refer to the Samaritan temple at Gerizim. It is also impossible to make out the relative importance of Jesus and Simon in the system. The Simonians evidently believed that the same divine principle was incarnate in both, but the reference to the Passion shows that they could not have confused the two historical figures. Further clarity cannot be expected as Irenaeus was not sufficiently interested or well informed to describe the doctrine of salvation in detail.

More remote from the original stock is a system preserved in a document quoted at length by Hippolytus and entitled "the Great Pronouncement" (apophasis megale). Here fragmentary survivals of the original Simonian myth serve only to cloak a philosophic system allied to Stoicism. Elaborate metaphor and fanciful exegesis do much to obscure the meaning and the affinities with other known Simonian systems are very slight. The substitution of an innate saving principle in human nature for a personal saviour is reminiscent of Saturninus, but the underlying ideas are more philosophical and myth serves only as a symbol, not as a naïve statement of fact. Still more tenuous is the connection between Irenaeus' account and a system of theology attributed to Simon in the Clementines, but this problem can be satisfactorily treated only after further research on the text and sources of that literature have been made.

Both Irenaeus and Hippolytus inform us of the liturgical practices of the Simonians. Apart from magic of various kinds, wor-

ship was paid to Simon and Helen before statues of Zeus and Athena. It was, however, customary not to mention their names but to use the titles "Lord" and "Mistress" (kyrios, kyria). Any-one violating this convention was detected as an outsider and expelled from the mysteries. (R. P. C.)

SIMON OF ST. QUENTIN (*fl.* 1247), Dominican mission-traveller and diplomatist, accompanied, and wrote the history of the Dominican embassy under Friar Ascelin or Anselm, which Pope Innocent IV. sent in 1247 to the Mongols of Armenia and Persia. Large sections of Simon's history have been preserved in Vincent of Beauvais's *Speculum historiale,* where 19 chapters are expressly said to be *ex libello fratris Simonis,* or entitled *frater Simon.* The embassy proceeded to the camp of Baiju or Bachu *Noyan* (*i.e.,* "General" Baiju, *Noyan* signifying a commander of 10,000) at *Sitiens* in Armenia, lying between the Aras river and Lake Gokcha, 59 days' journey from Acre. The papal letters were translated into Persian, and thence into Mongol, and so presented to Baiju; but the Tatars were irritated by the haughtiness of the Dominicans. The Frankish visitors were treated with contempt: for nine weeks all answer to their letters was refused. Thrice Baiju even ordered their death. At last, on July 25, 1247, they were dismissed with the *Noyan's* reply, dated July 20, which complained of the high words of the Latin envoys, and commanded the pope to come in person and submit to the Master of all the Earth (the Mongol emperor). The mission thus ended in complete failure.

See Vincent of Beauvais, *Speculum historiale,* book xxxii. (sometimes quoted as xxxi.), chaps. 26–29, 32, 34, 40–52 (*cf.* pp. 453 A-454 B in the Venice edition of 1591); besides these, several other chapters of the *Spec. hist.* probably contain material derived from Simon, *e.g.,* bk. xxxi. (otherwise xxx.), chaps. 3, 4, 7, 8, 13, 32; and bk. xxx. (otherwise xxix.), chaps. 69, 71, 74–75, 78, 80. *See* also d'Ohsson, *Histoire des Mongols,* ii. 200–201, 221–233; iii. 79 (edition of 1852); Fontana, *Monumenta Dominicana,* p. 52 (Rome, 1675); Luke Wadding, *Annales Minorum,* iii, 116–118; E. Bretschneider, *Mediaeval Researches from Eastern Asiatic Sources,* vol. i., notes 455, 494 (London, 1888); M. A. P. d'Avezac's Introduction to Carpini, pp. 404–405, 433–434, 464–465, of vol. iv. of the Paris Geog. Soc.'s *Recueil de Voyages,* etc. (Paris, 1839); W. W. Rockhill, *Rubruck,* pp. xxiv.–xxv. (London, Hakluyt Soc., 1900); C. R. Beazley, *Dawn of Modern Geography,* ii. 277, and *Carpini and Rubruquis,* 269–270.

SIMONSTOWN, a town and naval station of the British navy in South Africa on False bay, and 22½ m. by rail from Cape Town. In 1910 works were completed, which provide a tidal basin of 26 ac., with a depth of 30 ft. at L.W.O.S.T. South of this basin is a large, reclaimed area, the site of the new dockyards. The hill behind the town is fortified. Simonstown dates from the close of the 17th century, and is named after Simon van der Stel, governor of the Cape, 1679–99. Pop. (1926) 5,000, of whom 2,660 were whites. On the southern side it is developing as a seaside resort.

SIMONY, an offence, defined below, against the law of the church. The name is taken from Simon Magus (*q.v.*). In the canon law the word bears a more extended meaning than in English law. "Simony according to the canonists," says Ayliffe in his *Parergon,* "is defined to be a deliberate act or a premeditated will and desire of selling such things as are spiritual, or of anything annexed unto spirituals, by giving something of a temporal nature for the purchase thereof; or in other terms it is defined to be a commutation of a thing spiritual or annexed unto spirituals by giving something that is temporal." In the *Corpus juris canonici* the Decretum (pt. ii. cause i. quest. 3) and the Decretals (bk. v. tit. 3) deal with the subject. The offender whether *simoniacus* (one who had bought his orders) or *simoniace promotus* (one who had bought his promotion), was liable to deprivation of his benefice and deposition from orders if a secular priest,—to confinement in a stricter monastery if a regular. No distinction seems to have been drawn between the sale of an immediate and of a reversionary interest. The innocent *simoniace promotus* was, apart from dispensation, liable to the same penalties as though he were guilty. Certain matters were simoniacal by the canon law which would not be so regarded in English law, *e.g.,* the sale of tithes, the taking of a fee for confession, absolution, marriage or burial, the concealment of one in mortal sin or the reconcilement of an impenitent for the sake of gain, and the doing homage for spiritualities. So grave was the crime of simony considered that even infamous persons could accuse of it. English provincial and legatine constitutions continually assailed simony.

For the purposes of English law simony is defined by Blackstone as the corrupt presentation of any person to an ecclesiastical benefice for money, gift or reward. The offence is one of purely ecclesiastical cognizance, and not punishable by the criminal law. The penalty is forfeiture by the offender of any advantage from the simoniacal transaction, of his patronage by the patron, of his benefice by the presentee; and now by the Benefices Act 1892, a person guilty of simony is guilty of an offence for which he may be proceeded against under the Clergy Discipline Act 1892. An innocent clerk is under no disability, as he might be by the canon law. Simony may be committed in three ways—in promotion to orders, in presentation to a benefice, and in resignation of a benefice. The common law (with which the canon law is incorporated, as far as it is not contrary to the common or statute law or the prerogative of the Crown) has been considerably modified by statute. Where no statute applies to the case, the doctrines of the canon law may still be of authority. Both Edward VI. and Elizabeth promulgated statutes against simony.

The general result of the law before the Benefices Act 1898, as gathered from statutes and decisions, may be stated as follows: (1) it was not simony for a layman or spiritual person not purchasing for himself to purchase, while the church was full, an advowson or next presentation, however immediate the prospect of a vacancy; (2) it was not simony for a spiritual person to purchase for himself a life or any greater estate in an advowson, and to present himself thereto; (3) it was not simony to exchange benefices under an agreement that no payment was to be made for dilapidations on either side; (4) it was not simony to make certain assignments of patronage under the Church Building and New Parishes Acts; (5) it was simony for any person to purchase the next presentation while the church was vacant; (6) it was simony for a spiritual person to purchase for himself the next presentation, though the church be full; (7) it was simony for any person to purchase the next presentation, or in the case of purchase of an advowson the next presentation by the purchaser would be simoniacal if there was any arrangement for causing a vacancy to be made; (8) it was simony for the purchaser of an advowson while the church was vacant to present on the next presentation; (9) it was simony to exchange otherwise than *simpliciter;* no compensation in money might be made to the person receiving the less valuable benefice. The law on the subject of simony was long regarded as unsatisfactory by the authorities of the church. In 1879 a royal commission reported on the law and existing practice as to the sale, exchange and resignation of benefices. Many endeavours were made in parliament to give effect to the recommendations of the commission, but it was not until 1898 that any important change was made in the law. The Benefices Act of that year absolutely invalidated any transfer of a right of patronage unless (*a*) it is registered in the diocesan registry, (*b*) unless more than 12 months have elapsed since the last institution or admission to the benefice, and (*c*) unless "it transfers the whole interest of the transferor in the right" with certain reservations; in other words, the Act abolished the sale of next presentations, but it expressly reserved from its operation (*a*) a transmission on marriage, death or bankruptcy or otherwise by operation of law, or (*b*) a transfer on the appointment of a new trustee where no beneficial interest passes. It also substituted another form of declaration for that required under the Clerical Subscription Act 1865, and this form has been again amended by the measure of 1923 (*infra*). It abolished the sale by auction of an advowson in gross, and empowered a bishop to refuse to institute or admit a presentee to a benefice on a number of specified grounds: among others, on the ground of possible corrupt presentation through a year not having elapsed since the last transfer of the right of patronage, and constituted a new court to hear appeals against a bishop's refusal to institute. This court consists of a judge of the Supreme Court, who shall decide all questions of law and of fact,

and of the archbishop, who gives judgment. The Benefices Act 1892 has now been amended in many details by the Benefices Act 1898 Amendment Measure 1923 and the Benefices Rules 1926.

In Scotland simony is an offence both by civil and ecclesiastical law. The rules are generally those of the canon law. There are few decisions of Scottish courts on the subject. By the Act of 1584, c. 5, ministers, readers and others guilty of simony provided to benefices were to be deprived. An Act of Assembly of 1753 declares pactions simoniacal whereby a minister or probationer before presentation and as a means of obtaining it bargains not to raise a process of augmentation of stipend or demand reparation or enlargement of his manse or glebe after induction.

In the United States, there is no recognition of simony in the courts.

SIMOOM, the name usually given in the Sahara and Arabian deserts to hot, dry whirlwinds experienced in spring and summer.

SIMPLICIUS, pope from 468 to 483. During his pontificate the Western Empire was overthrown, and Italy passed into the hands of the barbarian king Odoacer. In the East, the usurpation of Basiliscus (475–476), who supported the monophysites, gave rise to many ecclesiastical troubles, which were a source of grave anxiety to the pope. The emperor Zeno, who had procured the banishment of Basiliscus, endeavoured to compound with the monophysite party; and the bishop of Constantinople, who had previously fought on the pope's side for the council of Chalcedon, abandoned Simplicius and subscribed to the *henoticon,* the conciliatory document promulgated in 482 by the emperor. Simplicius died on March 2, 483, but without settling the monophysite question.

SIMPLICIUS, a native of Cilicia, a disciple of Ammonius and of Damascius, was one of the last of the Neoplatonists. When, in A.D. 529, the school of philosophy at Athens was disendowed and the teaching of philosophy forbidden, the scholars Damascius, Simplicius, Priscianus and four others resolved in 531 or 532 to seek the protection of Chosroes, king of Persia, but within two years they returned to Greece. After his return from Persia Simplicius wrote commentaries upon Aristotle's *De coelo, Physica, De anima* and *Categoriae,* which, with a commentary upon the *Enchiridion* of Epictetus, have survived. To the student of Greek philosophy his commentaries are invaluable, as they contain many fragments of the older philosophers as well as of his immediate predecessors.

SIMPLON PASS, a pass over the Alps. Not known early save as a purely local route, the Simplon Pass rose into importance when Napoleon caused the carriage road to be built across it between 1800 and 1807. The Simplon tunnel was opened in 1906. The pass proper starts from Brig in the upper Rhône valley, 90½ m. by rail from Lausanne. From Brig it is about 14 m. to the pass (6,592 ft.), close to which is the hospice (first mentioned in 1235) in charge of Austin Canons from the Great St. Bernard. The road descends past the Swiss village of Simplon, and passes through the wonderful rock defile of Gondo before entering Italy above Iselle (28 m. from Brig). Here the road joins the railway line through the tunnel, which is 12¼ m. in length, and 2,313 ft. high, being thus both the longest and the lowest tunnel through the Alps. From Iselle it is about 11 m. by rail to Domo d'Ossola, whence the Toce or Tosa valley is followed to the Lago Maggiore (23 m.).

SIMPSON, SIR JOHN (WILLIAM) (1858–), British architect, was born on Aug. 9, 1858, educated privately, and studied at the Royal Academy. He became a fellow of the Royal Institute of British architects in 1900, and was vice-president on two occasions, and president from 1919 to 1921. His works include the school buildings of Roedean, Brighton, extensions of Haileybury, Winchester, and Lancing colleges. He has also designed a number of memorials and many private houses. He was joint architect of the National Hospital for the Paralysed and Epileptic, London, and designed the Grafton Street hospital, Liverpool.

SIMPSON, MATTHEW (1811–1884), American bishop of the Methodist Episcopal Church, was born in Cadiz (O.) on June 21, 1811. Largely self-educated, he began to practise medicine in 1833, but the same year was licensed as a preacher of the Methodist Episcopal Church. After a couple of western pastorates, in 1837 he was appointed professor of natural science in Allegheny college, Meadville; and was from 1839 until 1848 president of the newly established Indiana Asbury (now De Pauw) university, Greencastle (Ind.). He was editor of the *Western Christian Advocate,* which he made a strong temperance and anti-slavery organ, from 1848 to 1852. He was elected a bishop in May, 1852. He died on June 18, 1884, in Philadelphia. He published *A Hundred Years of Methodism* (1876) and *Lectures on Preaching* (1879), and edited a *Cyclopedia of Methodism* (1878). A volume of his *Sermons* (1885) was edited by G. R. Crooks.

See his *Life* by G. R. Crooks (1890) and E. M. Wood, *The Peerless Orator* (1909).

SIMROCK, KARL JOSEPH (1802–1876), German poet and man of letters, was born on Aug. 28, 1802, at Bonn, where his father was a music publisher. He studied law at Bonn and Berlin, and in 1823 entered the Prussian civil service, from which he was expelled in 1830 for writing a poem in praise of the French July revolution. He became lecturer and eventually (1850) professor at Bonn, where he died on July 18, 1876. Simrock established his reputation by his excellent modern rendering of the *Nibelungenlied* (1827), of the poems of Walther von der Vogelweide (1833), and other Old High German poems.

Of his republications the most popular and the most valuable were the *Deutsche Volksbücher,* of which fifty-five were printed between 1839 and 1867. His best contribution to scholarship was his *Handbuch der deutschen Mythologie* (1853–55). Simrock took a high place among students of Shakespeare by his *Quellen des Shakespeare in Novellen, Märchen und Sagen* (1831); and afterwards he translated Shakespeare's poems and a considerable number of his dramas. His *Ausgewählte Werke* were published by G. Klee (12 vols., 1907). See N. Hocker, *Karl Simrock, sein Leben und seine Werke* (1877).

SIMS, GEORGE ROBERT (1847–1922), English journalist and dramatic author, was born on Sept. 2, 1847. He was educated at Hanwell college and at Bonn, and commenced journalism in 1874 as successor to Tom Hood on *Fun.* His first play, *Crutch and Toothpick,* was produced at the Royalty Theatre in April 1879, and was followed by a number of plays of which he was author or part-author. After long runs at west end houses, many of these became stock pieces in suburban and provincial theatres. His most famous melodramas were: *The Lights of London* (Princess's theatre, September 1881), which ran for nearly a year. and *Two Little Vagabonds* (Princess's Theatre, 1896–97), and among his musical plays were *Blue-eyed Susan* (Prince of Wales's, 1892) and *The Dandy Fifth* (Birmingham, 1898). His early volumes of light verse were very popular, notably *The Dagonet Ballads* (1882), reprinted from the *Referee.* He published a book of reminiscences, *My Life,* in 1917. He died in London on Sept. 4, 1922.

SIMS, WILLIAM SOWDEN (1858–), American naval officer, was born of United States parents at Port Hope, Ont., Canada, on Oct. 15, 1858, removing in childhood to Pennsylvania. He graduated from the U.S. Naval Academy in 1880, and for eight years served on board various ships in the North Atlantic. During 1889–93 he was with the nautical school ship "Saratoga," was transferred to the Pacific station, and later to the China station. From 1897–1900 he was naval attaché to the American Embassy, at Paris and at St. Petersburg (Leningrad), but in 1900 he returned to the Pacific station. Convinced of the inadequacy of American methods of target practice, he pressed his views upon the Government, and in the end was enabled to arrange for a gunnery test and prove his claims. This resulted in his being made inspector of target practice in the bureau of navigation, where he served seven years (1902–09). In 1907 he was made commander and appointed naval *aide* to President Roosevelt, and in 1909 he became commander of the battleship "Minnesota." During a visit of the Atlantic fleet to England in 1910, Commander Sims caused a stir at a dinner at the Guildhall, London, where he said: "Speaking for myself, I believe that if the time ever comes when the British empire is menaced by an external enemy you may count upon every man, every drop of

blood, every ship and every dollar of your kindred across the sea." A semi-official protest against this utterance was made at Washington by the German Government, but the incident ended in a severe reprimand from the President of the United States.

In 1911 Sims was promoted captain, and for two years was a member of the class of the Naval War college, Newport, Rhode Island. During 1913–15 he was in command of the Atlantic torpedo flotilla, and in 1916 in command of the battleship "Nevada." In Jan. 1917 he returned to Newport as president of the Naval War college. When America entered the World War in April 1917 he was chosen to command the American naval forces in European waters. In Jan. he had been promoted rear admiral, and in May he was given the temporary rank of vice admiral. On the conclusion of the war he relinquished command of the fleet, and in Feb. 1919 resumed his position as president of the Naval War college. In 1920 he made a formal report to the U.S. Navy Department charging it with serious errors in the conduct of naval operations during the war. He has published, in collaboration with Burton J. Hendrick, *The Victory at Sea* (1920).

SIMSON, WILLIAM (1800–1847), Scottish portrait, landscape and subject painter, was born at Dundee in 1800. He studied under Andrew Wilson at the Trustees' Academy, Edinburgh, and his early landscape and marine subjects found a ready sale. He next turned his attention to figure painting, and in 1830 was elected a member of the Scottish Academy. On the proceeds of his portrait-painting, he spent three years in Italy, and on his return in 1838 settled in London, where he died on Aug. 29, 1847. Simson is greatest as a landscapist; his "Solway Moss—Sunset," exhibited in the Royal Scottish Academy of 1831 and now in the National Gallery, Edinburgh, ranks as one of the finest examples of the early Scottish school of landscape.

His subject pictures include the "Twelfth of August" (1829), the "Highland Deerstalker" (1830); and among later works the "Camaldolese monk showing relics," "Cimabue and Giotto," the "Dutch Family," and "Columbus and his Child."

SIN is the name given to moral evil, when regarded from the point of view of religion, as distinguished from that of civic law or that of ethics. The Christian's ideal is to do all things as unto the Lord; and he looks upon his shortcomings as offences against a divinely given law or as grieving the Holy Spirit. But if this aspect of sin, or the religious associations with which moral evil is tinged, be of high significance for religious life, the nature of sin as moral evil correlated with responsibility and guilt, is fundamentally a question for ethics and psychology. That "sin is lawlessness," even when the law transgressed is regarded as divine, is a description which needs amplification, in order to fulfil the requirements of theological doctrine.

Of the several conditions of accountable moral conduct, the one just indicated may be treated first; the forthcomingness of a law, of which sin is transgression; or of a mark, of which sin is the missing. Moral law is a social acquisition; and knowledge of it is socially mediated, not innate to the individual. It is only when we begin to find certain kinds of behaviour expected of us, as what we owe, and become spectators of our conduct from the point of view from which others see us, that conscience emerges in us. It is not inborn, like instinct; nor does the soul possess it, before embodiment. We are born non-moral, not sinners. Further, St. Paul's teaching, that where no law is, sin cannot be imputed, needs to be supplemented. This brings us to the second condition of the possibility of sin. In order that an individual be accountable, it is not enough that there is moral law forthcoming, whether primitive customs or unconditional standards of Christian ethic; he must be aware of them as binding on himself, and must be in a position to perceive his act to be a shortcoming at the time of its occurrence. This reference to time is also essential. For instance, a heathen who may be blameless as to such law as he knows, is no sinner against Christian law that, as yet, he cannot know; and if he become a Christian and learn a higher ethic, he cannot then rightly accuse himself of guilt, in that, in his heathen past, he left undone what, had he been a Christian he should have done. The conduct of the infant that knows no law, or that of the adult heathen who obeys some law but knows not the highest, cannot even from the Christian standpoint, be deemed sinners. Else we should have to attribute sin to snakes and volcanoes. For the only relevant difference between the moral and the non-moral agent, is that the former can, and the latter cannot, be aware of law having dominion over it. We cannot assert sin to be non-compliance with moral law, as distinct from known moral law, without destroying the ethical significance of sin. All sin is imperfection; not all imperfection is sin. Thus it follows that there cannot be one absolute standard of perfection, to fall short of which, in any conditions and at any stage of moral enlightenment, convicts of sin. The only relevant standard is comparable to a sliding scale: it is what, to the all-seeing eye of God, is the highest that a given agent can recognize, at the time of his activity that is in question. Hence the wisdom of the counsel; "then at the balance let's be mute." Development is incompatible with perfection; the Christian, of all men, cannot say it is incompatible with sinlessness.

Turning now from the moral law and knowledge thereof to the acts and conduct to which ethical standards are applicable, we may consider the remaining conditions of what, in the strict sense, is to be called sin. Conscience and moral status, it has been said, are not innate; they are socially acquired, as human experience evolves from its earliest stages. But certain instincts and impulsive or appetitive tendencies are undoubtedly inherited. That is to say that in the body, with which an individual subject or soul becomes associated, are already ingrained aptitudes, etc., transmitted and fixed by heredity, which evoke specific reactions and responses from the soul, with its actual and potential faculties and capacities. Such appetites, instincts, strivings, etc. are involuntary, because, as yet, will or volition is not in existence. They are necessary and inevitable; the embodied soul is not responsible for them, and had no part in moulding them. They are also, from the biologist's point of view, natural or normal; not the outcome of derangement. Some of them, at least, are essential to the health and life of both individual and race. Theology must affirm that they belong to man, as it has pleased God to make him, *i.e.*, through evolutionary process. Lastly they are not only non-moral, in that they are involuntary and prior to conscience, but also neutral, in respect of what shall eventually be made out of them by the moralized person. They are the basis of virtues as well as of vices. In themselves, therefore, these propensities, or tendencies of the stock, are not sinful; no natural passion is base-born or condemnable. They are, however, the primary stuff out of which sinful conduct is shaped. But it is the will that shapes, not the stuff that is shaped, which alone calls for moral evaluation. They can no more be wicked than can alcohol or prussic acid. For the fact that they are strongly entrenched in us at birth, we are not responsible. Nor are we responsible, for the fact that they continue to assert themselves clamorously, after will and conscience have been acquired, and without respect for moral considerations; though it is thus that arise most of the "manifold temptations that death alone can cure." Temptation, however, is not sin; nor is temptability a sign of sinfulness—it is a condition of morality. But before these ethical and psychological reflections suggested themselves with the urgency they now possess, it was usual, and indeed natural, to call such inborn propensities sinful. Hence the expressions "inherited sin" and "original sin." Theologians who have framed and taught the doctrine of original sin have generally, though not universally, been willing to allow that original sin is not sin proper, and that, unlike actual sin, it is not a matter of moral responsibility and guilt. It is now generally admitted to be "sin" in but a figurative sense. Some would urge that retention of the old name "original sin" is no longer expedient, because ministering to confusion and inconsistency. What is "original" in the sense of innate or thrust upon us willy-nilly, cannot strictly be called sin. The root of sin is not a sinful root. For the fourth condition of the possibility of sinful activity is volition, and indeed intention. There must be capacity to choose between higher and lower ends, as has been recognized throughout the history of the doctrine of sin. Consequently, if there be in us, as some authorities have maintained, a moral taint that cleaves to us at our birth; some tendency, the origin of which must be beyond the conscious exercise of our freedom of will; an abiding root of sin,

which a man finds present in himself when his moral consciousness awakes; it must be brought by the soul itself, and have been contracted voluntarily in a life previous to the soul's embodiment. This speculative view has found supporters here and there down the ages; but we have no knowledge as to such life, and certainly, if the soul possessed such moral volition before embodiment, it must somehow have become dispossessed of it on entering into this life, because psychology can trace the development of volition and conscience which, at birth, are absent. This suggestion, like all other forms of doctrine of a fall, whether of the race collectively or of each soul singly, has doubtless been cherished because it has seemed difficult to many minds to account otherwise for the prevalence—often assumed to be strictly universal—of sinfulness throughout mankind; also, perhaps, because it seems to explain the emergence of moral evil in God's good world. But, as for the former of these motivations, it is enough to know that the race has solidarity in respect, not of ready-made sin, but of the non-moral appetites, etc. which prompt the will to evil choice. As for the latter of them, any kind of fall such as is invoked to account for racial sinfulness, would seem only to put the difficulty further back, not to eliminate it. Evil must have entered into the human world somehow and at some time, whether in Adam, or in Satan, or in each soul in a previous life; and that presents just the same difficulty as does the origination of sin in each man in this life. Indeed, in the case of the theory that sin originated in a previous life, the difficulty would seem to be increased. For had we all been in the same case as Milton's Satan, to account for all sinning without exception, each being the Adam of his own soul, and that before embodiment, is hardly possible; whereas our bodily nature supplies the motives which make our sinfulness explicable enough, however condemnable it be. On the other hand, the traditional doctrine that we all owe our sinfulness to the sin of the first parent of the race, either offends our moral consciousness and sense of responsibility or else confounds sinfulness with the non-moral "material" out of which our will makes sin.

Sin has, so far, been dealt with only in its elemental aspects and its earliest stages. It is, in fact, there that we encounter the controversial issues, and the features of the problem that present most difficulty and most interest for theology. The more advanced and complex stages present no further disputable issues. But it should be observed that from the dawn of volition, of thought or ideation, and of morality, our blind springs of action cease to be blind. When imbued with volitional response, they become desires, and eventually personal attitudes. Actions engender habits; emotions establish sentiments; and so on. We soon discover that appetites, the satisfaction of which yields pleasure, can be stimulated, in order to be enjoyed. Hunger may be voluntarily transformed into gluttony, sensibility into voluptuousness; and as knowledge and experience widen the lengths to which "making provision for the flesh" can be carried, become indefinitely extended. But it is not necessary to follow further the development of the intricacy of the moral life of man; the essentials for a sound psychology of sin are manifested, and can be most clearly studied, in the primary moral situations to which attention has here been almost exclusively directed.

LITERATURE.—For a critical account of the main theories and treatment from the standpoint of sin-consciousness, *see* W. E. Orchard, *Modern Theories of Sin* (1909). For a discussion of sin on the lines indicated above, *see* F. R. Tennant, *The Concept of Sin* (1912). (F. R. T.)

SIN, the name of the moon-god in Sumerian, derived from *zu-en,* usually written *en-zu,* "lord of wisdom." He became one of the principal deities of the (Semitic) Babylonian pantheon, and only in the period of the later West Semitic occupation (22nd–18th centuries) is found any trace of the pure Semitic cult of the moon god, when the title *'ammu, ḥammu* "uncle" appears. As god of the new moon he has the title *šeš-ki,* "brother of the earth," pronounced by the Semites *Nannar*>*Nanna.* The chief seats of his worship were Ur in the South and Harran in northern Assyria, but the cult at an early period spread to other centres, and temples to the moon-god are found in all the large cities of Babylonia and Assyria. During the period (*c.* 2399–2282 B.C.) that Ur exercised a large measure of supremacy over the Euphrates valley, Sin was naturally regarded as the head of the pantheon. It is to this period that we must trace such designations of the god as "father of the gods," "chief of the gods," "creator of all things," and the like. The development of astrological science culminating in a calendar and in a system of interpretation of the movements and occurrences in the starry heavens would be an important factor in maintaining the position of Sin in the pantheon. The name of Sin's chief sanctuary at Ur was E-gish-shirgal, "house of the great light"; that at Harran was known as E-khul-khul, "house of joys." On seal-cylinders he is represented as an old man with flowing beard, with the crescent as his symbol. In the astral-theological system he is represented by the number 30, and the planet Venus as his daughter by the number 15. The number 30 stands obviously in connection with the thirty days as the average extent of his course until he stands again in conjunction with the sun. The "wisdom" personified by the moon-god is likewise an expression of the science of astrology in which the observation of the moon's phases is so important a factor. The tendency to centralize the powers of the universe leads to the establishment of the doctrine of a triad consisting of Sin, Shamash and Ishtar (*q.v.*), personifying the moon, sun and Venus.

Nabunidus, the last king of Babylonia, inaugurated a movement to elevate the cult of Sin to the supreme place in religion, a movement clearly based upon astrological and astronomical theory that the triad, moon, sun and Venus are the controlling forces of divine providence. There is no doubt but that the emphasis placed upon moon worship by Sargon of Agade is due to his Semitic connection; in Arabia and throughout the Semitic races of Western Asia the moon god was from the beginning the most important deity. The consort of Sin was Ningal, to whom a special temple was built at Ur, and her cult was widely known in Syria where her name appears as Nikal. The cult of the Babylonian Sin seems to have been particularly favoured by the Assyrian colony in Cappadocia in the 21st–19th centuries, and among the Hittites of Anatolia and Syria.

SINAI, the mountain which has given its name to the "Sinaitic peninsula," the triangle lying between Egypt, South Palestine, Arabia and the Red sea. The mountain is famous in the Old Testament for the law-giving to Moses and the Israelites when they entered into covenant relations with the God who had delivered them from Egypt (Ex. xix. *seq.*). The events, which are the preludes to the journeys into Palestine, stand at the head of the national history of Israel; and Sinai and other places to the south of Palestine (Kadesh, Edom, Mt. Seir, Paran, Midian) are firmly established in tradition as, in some sense, the true home of the national god Yahweh (Deut. xxxiii. 2., Judges, v. 5, Hab. iii. 3, Ps. lxviii. 8).

Mt. Sinai, whose name connects it with the old Babylonian moon-god Sin, is also known as Horeb (1 Ki. viii. 9, Mal. iv. 4, etc.): and not only is the site disputed, but it is possible that they were originally two mountains, which later harmonizing tradition has combined. It has long been felt difficult to suppose that the Sinaitic peninsula could have been the scene of the wanderings of the immense body of Israelites, as described, and a careful study of the biblical narratives has raised questions which have not yet been adequately answered. Analysis has made it probable that Kadesh-Barnea (50 m. S. of Beersheba) was the scene of some of the most important incidents now placed at Sinai, and the mount of the law-giving, or, perhaps, more especially Mt. Horeb, should possibly be looked for in Midian, east of the Gulf of Akaba. (*See* JETHRO.)

The northern part of the Sinaitic peninsula has the ancient oft-trod road between Egypt and Palestine, one of the most famous in all history. Farther south is the bare and gradually rising region known as the wilderness of et-Tih ("wandering"). Two very important roads meet at the station of el-Nakhl, one running from Suez eastward to Akaba (the pilgrim road), another from Gaza southwards, opening out into various parts of the

mountainous district of Sinai itself. Here, the Jebel Serbal (6,750 ft.) and the Jebel Musa (7,359 ft.) compete for the honour of being the mount of the law-giving.

There is no genuine pre-Christian tradition on the subject. The chief authority for the ancient sanctity of Mt. Sinai is Antoninus Martyr (end of the 6th century A.D.), who tells that the heathen Arabs in his time still celebrated a moon feast there. As Sin was a moon-god, the feast has been connected with the name of Sinai. Of Arab origin, too, are the innumerable "Sinaïtic inscriptions," found especially in the Wādy Mokatteb (in the north-west), and sometimes accompanied by rude drawings. The language and character are Aramaic (Natabaean), but the proper names are mainly those of Arabs, who passing by graved their names on the rocks. That they were pilgrims to Sinai cannot be made out with certainty. The inscriptions date from the early centuries of the Christian era. In early Christian times, when the peninsula was once better wooded, many anchorites inhabited Sinai, living for the most part in the caves, which are numerous even in the primitive rocks. Monasteries were built, the most famous being the great one of St. Catherine in Wādy el-Dēr (the valley of the monastery). On Serbāl, too, there were many granite dwellings, and in the neighbouring Pharan (Phoenicion), which was a bishop's see, there were, as the ruins show, churches and convents. Josephus says that Sinai was the highest mountain of the district—a description which might apply to Serbāl as seen from the plain below. Eusebius uses expressions which may also seem to point to Serbāl as the place of the law-giving; whereas the tradition which seeks the holy site in the group of Jebel Mūsā (*i.e.,* the mass of which Mt. Catherine is the highest peak) is not older than the time of Justinian, and, on the whole, in spite of some good authorities, is of less value.

The southern half of the peninsula was famed for its stone, and its mines of copper and turquoise (malachite). At the Wady Maghara and Serabit el-Khadem the Egyptians have left abundant traces of settlements which testify to the constant exploitation of the turquoise mines from the Ist Dynasty onwards. Sinai, too, may have been the land of Magan, whence the Babylonians obtained stone as early as the days of Naram-Sin. In any case the peninsula as a whole must have had considerable strategical and economic importance from very ancient times. It is of special interest, therefore, that remains were found at Serabit of a highly developed cult in connection with the mines. The place has been described by Sir W. M. Flinders Petrie (1905). Although King Snefru, the last of the IIIrd Dynasty, came to be regarded as a sort of tutelary deity, the real guardian was the goddess Hathor, the "lady (or mistress) of turquoise." Her shrine was in a cave, in front of which buildings ran out for a distance of 250 feet. Adjoining the cave was the shrine of Sopdu, the lord of the deserts, and among the more noteworthy indications of an ancient and long-enduring cult was an enormous mass of ashes (estimated at 50 tons) in front of the cave, though the purpose of the ceremonial burnings is unknown.

As Petrie recognized, Hathor represents some Semitic deity. Her cult was Semitic and not Egyptian, and was earlier than any known in Palestine or Arabia. Her Semitic title "baalath" (on which *see* BAAL) was subsequently read upon some remarkable inscribed monuments written in characters which come between the Egyptian hieroglyphs and ancestral Semitic and European alphabets. They are of the XVIIIth Dynasty, and possibly the XIIth; and although the inscriptions still defy complete decipherment, the supposition that they were by, or refer to, the Israelites is—as yet at least—as baseless as an early view that the Aramaean "Semitic inscriptions," mentioned above, had a like origin. The script is of exceptional interest for the problem of the alphabet. It is disputed whether it is to be regarded as the actual ancestor of the two great branches: (1) the South Arabian, (2) the North Semitic (Phoenician, etc.) and the Greek, or whether it is only one of other forms once current before the types became fixed. In any event, since the Sinaitic peninsula touches the Delta and the South Palestinian towns of Rhinocolura (el-'Arish) and Gaza, both of which were in contact with North Arabia and the Levant, its situation makes it a natural centre for the rise and distribution of the alphabet (*q.v.*).

The resources of the peninsula would obviously attract the attention of peoples other than those of Egypt and Babylonia. Amenemhet III. (XIIth Dynasty) and Queen Hatshepshut (XVIIIth Dynasty) industriously exploited Serabit, and with the Ramessids traces of Egypt come to an end. But the invasion of Egypt by the Hyksos (whose seat was at the Delta city of Avaris) comes between the first and second of these periods, while the third marks the decline of Egypt and the increase of Semitic power. It is very unlikely, therefore, that the wealth of the peninsula was appreciated only by Egypt. The peninsula was the meeting-place of diverse influences. It was exposed, on the north, to Aegean, Philistine and other peoples of the eastern Mediterranean. The "land of the Philistines" extended southwards from Gath, Gaza and Gerar (Gen. xxvi., Deut. ii. 23, 1 Sam. xxvii. 8–11); and it is noteworthy that hereabouts are found the markedly un-Semitic names (Kadesh-) Barnea, Ziklag and 'Amālek (perhaps an Arab plural of some such form as 'Amlak). It is not known whether they point to Philistine or related influence. (*See* PHILISTINES.) They do not seem to be Egyptian, although Egyptian influence can be traced as far east as Tema (Teima) in North Arabia. Egypt (*see* MIZRAIM) would lay claim to the whole peninsula, and the "Wady of Egypt" (el-Arīsh) formed the northern end of the boundary. (*Cf.* 1 Ki. viii. 65.) None the less, the peninsula was Semitic rather than Egyptian, and was occupied by tribes with South Palestinian connections. Biblical tradition groups all these under Hagar and Ishmael, Esau, Edom, Mt. Seir and the Horites, and Abraham's concubine Keturah. Moreover, the Horite name Lotan, with which Lot, the ancestor of Ammon and Moab, may no doubt be connected, seems to be an echo of Retenu, an Egyptian name for Palestine; and whether this be so or not, the fact that men of Retenu are explicitly mentioned in Egyptian inscriptions of the XIIth Dynasty at Serabit, unites the peninsula naturally with the Semites of Palestine.

How the name Sinai arose can hardly be determined. There is a wilderness of Sin (Exod. xvi. 1)—Zin (Deut. xxxii. 51, etc.) is quite different—and Sin (Ezek. xxx. 15; old Egyptian *sinw*), situated at or near Pelusium, may have the same meaning. The appearance of the old Babylonian moon-god Sin in this part of the Semitic world is as striking as that of Baal-Zephon, the "Mountain of the north," by the Red Sea (*see* Exod. xiv. 2), and of Mt. Nebo in Moab (Deut. xxxii. 49, *seq.*). These names, with the Semitic cult at Serabit, and the remains of a more or less contemporary sanctuary at ed-Dra, in Moab, point to some definite religious culture long before Israelite times. Sin, the moon-god, had his most famous seats at Ur in Babylonia and at Harran in North Syria; and when, in the 6th century B.C., Nabonidus interested himself in the moon-cult at these places, he also visited Teima in North Arabia—presumably for the same reason. Hebrew tradition claimed, through Abraham (*q.v.*), an early relationship with both Ur and Harran, and some evidence has been adduced by scholars to suggest that Yahweh, the god of Israel, was probably once regarded as a moon-god. (*See* Burney, *Judges*, pp. 249, *seq.*) Yet while the moon-cult seems to have been particularly prominent in early Semitic religion, and in the Sinaitic area, it is not the moon-god but the sun-god who, as god of justice, would be most naturally associated with a law-giving, even as it is from the sun-god Shamash that the Babylonian law-giver Hammurabi received his great code. The religious history of the Sinaitic area goes back to a remote date, and is pre-Israelite; but the biblical narratives have their own national traditions of its significance for them, and these must be subjected to a critical analysis. (*See* AARON, MOSES, EXODUS, NUMBERS and HEBREW RELIGION.)

(S. A. C.)

SINAIA, a town of Rumania, on the railway from Ploeşçi to Braşov in Transylvania. Pop. (1928), 6,400. Sinaia resembles a large model village, widely scattered among the pine forests of the lower Carpathians, and along the banks of the Prahova, a swift

alpine stream. The monastery of Sinaia, founded by Prince Michael Cantacuzino in 1695, was the residence of the royal family until the present chateau was built. Its library contains valuable jewels belonging to the Cantacuzene family. Castle Peleş, the modern palace, named after the hill on which it stands, is of a mixed style of architecture on the whole Germanic. Until 1850 Sinaia consisted of little more than the monastery and a group of huts.

SINALOA, a State of Mexico, on the Gulf of California, with a coast line of nearly 400 miles. Area, 27,557 sq.m. Pop. (1910), 323,642; (1921), 341,265. The surface consists of a narrow coastal zone where tropical conditions prevail, a broad belt of mountainous country covered by the ranges of the Sierra Madre Occidental and their intervening valleys where oak and pine forests are to be found, and an intervening zone among the foothills of the Sierra Madre up to an elevation of 2,000ft., where the conditions are subtropical. The State is traversed by numerous streams, the largest of which have broad valleys among the foothills. The largest of these are the Culiacán, Fuerte and Sinaloa, the last two having short navigable courses across the lowlands.

Rain is plentiful everywhere, except in the extreme north, where the conditions are arid. The climate of the low-lying coast lands is hot; however, in the mountains it is cool and healthy. Cereals and *mezcal* are produced on the uplands, and sugar, rum, coffee, tobacco, grape spirits and fruit in the lower zones. There are excellent cotton lands in the State and the production of this staple was largely developed during the American Civil War, but has since declined. In recent years large quantities of tomatoes have been raised, chiefly for the American market. Grazing receives considerable attention in the uplands, where the temperature is favourable and the pasturage good, and hides are largely exported. Mining, however, is the chief industry, Sinaloa being one of the richest mineral-producing States in the republic. Gold, silver, copper, iron and lead are found. There are also salt deposits and mineral springs. The best-known silver mines are the Rosario, from which about $90,000,000 had been extracted up to the last decade of the 19th century, and the Nuestra Señora de Guadalupe de los Reyes, discovered early in the 19th century and yielding over $85,000,000 before its close. The forest products of the State include rubber, resins, cabinet and dye-woods, orchilla and ixtle fibre. Up to the beginning of the 20th century Sinaloa had only one short railway, which connected Culiacán with its port Altata. Since then the Mexican branch of the (American) Southern Pacific railway from Nogales to Guaymas has been extended south-east along the coast to connect the railways of central Mexico. Sinaloa has excellent natural harbours, only two of which —Mazatlán and Altata—are much used. The Bays of Agiobampo and Topolobampo are prospective railway terminals with fine harbours. The capital of the State is Culiacán Rosales (commonly called Culiacán), on the Culiacán river 39 m. from its port, Altata, at the mouth of the same river, with which it is connected by rail. It is a well-built town, with some thriving manufactures, including cotton goods, cigarettes, liqueurs, etc. It is the see of a bishop and has a fine cathedral. Culiacán (pop. in 1910, 13,527; 1921, 16,034) is the distributing centre for a large district between Guaymas and Mazatlán. The next most important town is Mazatlán (pop. 25,254) one of the leading ports of Mexico on the Pacific coast, and the commercial centre for S. Sinaloa and N. Durango. Other towns are Mocorito (pop. 3,757 in 1921), Sinaloa (pop. 1,666 in 1921), and Fuerte (pop. 2,836 in 1921), all in the N. of the State, Rosario (pop. 7,050 in 1921), and San Ignacio (pop. 1,635 in 1921) in the South.

SINCLAIR, the name of an old Scottish family, members of which have held the titles of earl of Orkney and earl of Caithness. The word is a variant of Saint Clair.

Sir William Sinclair, or Saint Clair (*c.* 1260–*c.* 1303), was the descendant of a line of Anglo-Norman barons, one of whom obtained the barony of Rosslyn from King David I. in the 12th century. Sir William took part in the dispute over the succession to the crown of Scotland in 1292, and was one of the leaders of the Scots in their revolt against Edward I. His grandson Sir William Sinclair, was slain by the Saracens in August 1330, while journeying through Spain to Palestine with Sir James Douglas, the bearer of the heart of Bruce. This Sir William Sinclair married Isabel, daughter of Malise, earl of Strathearn, Caithness and Orkney (d. *c.* 1350), and their son Sir Henry Sinclair (d. *c.* 1400) obtained the earldom of Orkney by a judgment of the Norwegian king Haakon VI. in 1379. He then helped to conquer the Faeroe Islands, and took into his service the Venetian travellers, Niccolo and Antonio Zeno, sailing with Antonio to Greenland.

William, the 3rd earl of his line, whose earldom of Orkney was a Norwegian dignity, was made chancellor of Scotland in 1454 and Lord Sinclair and earl of Caithness in 1455. When in 1470 the Orkney Islands were ceded by Norway to King James III. he resigned all his rights therein to his sovereign and was known merely as earl of Caithness. His eldest son, William, having offended his father by his wasteful habits, the earl settled his earldom on his eldest son by another marriage, also called William, who was killed at Flodden in 1513. The elder William, however, inherited the title of Lord Sinclair, and the family was thus split into two main branches.

George, 4th earl of Caithness (*c.* 1525–1582), a son of the 3rd earl, was a Roman Catholic and a supporter of Mary Queen of Scots, but he was mainly occupied with acts of violence in the north of Scotland. His grandson George, the 5th earl (*c.* 1566–1643), was outlawed and compelled to fly to the Shetlands. He left many debts, and his great-grandson and successor, George, the 6th earl (d. 1676), who was childless, arranged that his estates should pass to a creditor, Sir John Campbell, afterwards earl of Breadalbane. Campbell was created earl of Caithness in 1677, but the title was also claimed by George Sinclair (d. 1698), a grandson of the 5th earl, and in 1681 the privy council decided in his favour. When Alexander, the 9th earl, died in 1765 the title was successfully claimed by William Sinclair (d. 1779), a descendant of the 4th earl, who became the 10th earl.

The title of Lord Sinclair passed from William, the 2nd lord, who died about 1488, to John (1610–1676), who became the 9th lord in 1615. At first a covenanter, afterwards he became a royalist, and was taken prisoner at the battle of Worcester. He died without male issue and the title became dormant. His estates, however, passed to his grandson, Henry St. Clair (1660–1723), the son of his daughter Catherine (d. 1666) and her husband, John St. Clair of Herdmanston, and in 1677 Henry was created Lord Sinclair with the precedence of the older title. He had two sons, John Sinclair (1683–1750) the Jacobite, and James Sinclair, who became a general in the British army, and was also ambassador at Vienna and Turin and a member of parliament for many years. After the attainder of John, in consequence of his share in the rising of 1715, the family estates were settled on James, but he resigned them to his elder brother when the latter was pardoned in 1726. The pardon, however, did not include the restoration of the title. Earlier in life John Sinclair had killed a man named Shaw in a duel and had afterwards shot this man's brother. He was tried by court-martial and sentenced to death, but was pardoned. An account of the proceedings in the court-martial was edited by Sir Walter Scott for the Roxburghe Club (Edinburgh, 1828). Sinclair himself wrote *Memoirs of the Rebellion*, published by the Roxburghe Club in 1858.

Neither of the brothers left male issue, and the title devolved upon a cousin, Charles St. Clair (d. 1775), who was not included in the attainder. Charles did not claim it, but in 1782 his grandson Charles (1768–1863) was declared to be Lord Sinclair. He was a Scottish representative peer from 1807 to 1859 and is the ancestor of the present holder of the title.

See Sir R. Douglas, *The Peerage of Scotland,* new ed. by Sir J. B. Paul; G. E. (Cokayne), *Complete Peerage;* Sinclair, *The Sinclairs of England* (1887); Sir R. Gordon and G. Gordon, *The Earldom of Sutherland* (Edinburgh, 1813), and Hay, *Genealogy of the Sinclairs of Roslin* (1835).

SINCLAIR, SIR JOHN, Bart. (1754–1835), Scottish writer on finance and agriculture, was the eldest son of George Sinclair of Ulbster, a member of the family of the earls of Caithness, and was born at Thurso Castle on May 10, 1754. After studying at Edinburgh, Glasgow, and Trinity College, Oxford, he

whom must be a barrister specially qualified to deal with mercantile cases.

Abbott, *Sind: A Re-interpretation* (1924); Royal Comm. on Agriculture in India 1928, Evidence taken in Sind, Bull. 150, Dept. of Agric., Bombay (1928). *See* also INDIAN DESERT bibliography. (A. V. W.)

SINDBAD THE SAILOR, VOYAGES OF, a collection of Arabic travel-romances, partly based upon experiences of oriental navigators (especially in the 8th–10th centuries); partly upon ancient poetry, Homeric and other; partly upon Indian and Persian collections of *mirabilia.* In Sindbad's First Voyage, from Baghdad and Basra, the incident of the Whale-Back island may be compared with the Indian ocean whales of Pliny and Solinus, covering four *jugera,* and the *pristis* sea-monster of the same authorities, 200 cubits long. With the Island of the Mares of King Mihraj, or Mihrjan, we may find (rather imperfect) parallels in Homer's *Iliad* (the mares impregnated by the wind), in Ibn Khurdadbih and Al Kazwini, and in Wolf's account of the three *Ilhas de Cavallos* near Ceylon, so called from the wild horses with which they abounded, to which the Dutch East India merchants of the 17th century sometimes sent their mares for breeding purposes. Sindbad's account of the kingdom of Mihraj (Mihrjan) is perhaps derived from the *Two Musulman Travellers* of the 9th century; it would seem to refer to one of the greater East Indian islands, perhaps Borneo. Sindbad's Valley of Diamonds has fairly complete parallels in Al Kazwini, in Benjamin of Tudela, in Marco Polo and in the far earlier Epiphanius, bishop of Salamis in Cyprus, who died A.D. 403. As to the Mountain, or Island, of Apes in the Third Voyage, Ibn Al Wardi and Idrisi each recognizes an island of this kind, the former in the China sea, the latter near Sokotra. Sindbad's negro cannibal adventure reproduces almost every detail of the Cyclops story in the *Odyssey;* among the Spice islands, and perhaps at Timor, may be located the island rich in sandal-wood, where the wanderer rejoins his friends. The cannibal land of the Fourth Voyage, producing pepper and coco-nuts, where Sindbad's companions were offered food which destroyed their reason, has suggested the Andamans to some enquirers and certain districts of Sumatra to others; with this tale we may compare the lotus-eating of the *Odyssey,* Plutarch's story of Mark Antony's soldiers maddened and killed by an "insane" and fatal root in their Parthian wars, a passage in Davis's *Account of Sumatra* in 1599, and more complete parallels in Ibn Al Wardi and Al Kazwini. The burial of Sindbad in, and his escape from, the cavern of the dead is faintly foreshadowed in the story of Aristomenes, the Messenian hero, and in a reference of St. Jerome to a supposed Scythian custom of burying alive with the dead those who had been dear to them; the fully-developed Sindbad tale finds an echo in "Sir John Mandeville." For the "Old Man of the Sea," in the Fifth Voyage, we may also refer to Al Kazwini, Ibn Al Wardi and the romance of Seyf Zu-l Yezen; Sindbad's tyrannical rider has usually been explained as one of the huge apes of Borneo or Sumatra, improved to make a better story.

See Richard Hole, *Remarks on the Arabian Nights' Entertainments, in which the Origin of Sindbad's Voyages . . . is particularly considered* (1797); Eusebius Renaudot's edition of the *Two Musulman Travellers* (1718, translated into English, 1733, as *Ancient Accounts of India and China by two Mahommedan Travellers . . . in the 9th Century*); J. T. Reinaud, *Relations des voyages faits par les Arabes et les Persans dans l'Inde et à la Chine dans le IXe siècle* (1845); E. W. Lane's translation of the *Arabian Nights* (1859), especially the notes in vol. iii. pp. 77–108; M. J. de Goeje, *La Légende de Saint Brandan* (1890); C. R. Beazley, *Dawn of Modern Geography* (1897), i. 235–238, 438–450.

SINDHI (properly *Sindhī,* the language of Sindh, *i.e.,* Sind) and **LAHNDA** (properly *Lahndā* or *Lahindā,* or *Lahndē-dī-bōlī,* the language of the west), two closely connected forms of speech belonging, together with Kashmiri (*q.v.*), to the north-western group of the outer band of Indo-Aryan languages.

The parent Prakrit, from which Lahnda is sprung, must once have extended over the greater part of the Punjab, but Lahnda and Sindhi, the western outposts of Indo-Aryan speech, have for centuries occupied a peculiarly isolated position, and have in many respects struck out common lines of independent growth. This process was aided by the presence of Dardic languages (*see* INDO-ARYAN LANGUAGES). In early times there were Dardic colonies along the Indus, right down to its delta, and both Sindhi and Lahnda have borrowed many peculiarities from their dialects.

Sindhi is directly derived from the Vrācaḍa Apabhraṁśa Prakrit (*see* PRAKRIT). The name of the Apabhraṁśa from which Lahnda is derived is not known, but it must have been closely allied to Vrācada. Sindhi has one important dialect, Kachchhī, spoken in Cutch. Here the language has come into contact with Gujarati and is somewhat mixed with that form of speech. (*See* also LAHNDA.)

Owing to their geographical position both Sind and the western Punjab were early subject to Mohammedan inroads. The bulk of the population is Muslim, and their languages make free use of words borrowed from Persian and (through Persian) from Arabic. The written character employed for Lahnda is usually that modification of the Persian alphabet which has been adopted for Hindustani. For Sindhi, further modifications have been introduced to represent special sounds. In both languages, Hindus also employ a script akin to the well-known Nagari alphabet (*see* SANSKRIT). It is the same as the "Laṇḍā" (a word distinct from "Lahndā") or "clipped" character current all over the Punjab and is very imperfect, being seldom legible to any one except its original writer, and not always so to him.

Phonetics.—The phonetic system of both languages in most respects resembles that of other Indo-Aryan vernaculars. In other Indo-Aryan languages a final short vowel is generally elided. This rule is also followed in Lahnda, but the genius of Sindhi requires every word to end in a vowel, and hence these short vowels are still retained. In Sindhi these final short vowels are very lightly pronounced, so that they are hardly audible. Lahnda, especially when dropping the final short vowel, has epenthetic changes, which have not been noted in Sindhi. In that language and in Lahnda the short vowel *i,* when preceded or followed by *h,* or at the end of a word, is pronounced as a short *e.*

In Lahnda the double consonant is generally retained, but in Sindhi, while the double consonant is simplified, the vowel remains short. An original long vowel coming before a conjunct consonant is shortened when the conjunct is simplified.

In Sindhi, a sibilant is liable to be changed into *h.* In Lahnda the *s* is generally, but not always, preserved. A medial *d* becomes the hard *r;* there is great confusion between cerebrals and dentals, more common in Sindhi than in Lahnda. In Sindhi, *t* and *d* become regularly cerebralized before *r.* The cerebral *l* does not appear in Sindhi, but it has survived from Prakrit in Lahnda. When *l* represents a Prakrit single *l,* it becomes *ḷ,* but if it represents a Prakrit *ll,* it remains a simple dental *l.*

Sindhi has a series of "recursive" consonants *g̅, j̅, ḍ̅,* and *b̅.* In sounding them the breath is drawn in instead of being expelled, *i.e.,* the larynx being lowered and the glottis closed. They often, but not always, represent an original double letter.

Declension.—Both languages have lost the neuter gender, all nouns being either masculine or feminine. The rules for distinguishing gender are much as in Hindustani. As in other Indo-Aryan languages, nouns may be either strong or weak, the strong forms being derived from nouns with the pleonastic Sanskrit suffix *ka.* In Sindhi, a masculine weak form in *u* corresponds to the strong one in *ō,* and feminine weak forms in *a* and *o* to a strong one in *i.* In Lahnda, weak forms have dropped the final short vowel, and the strong forms end in *ā* (masc.) and *ī* (fem.).

Almost the only old case that has survived throughout the declension of both languages is the general oblique. This is used for any oblique case, the particular case required being as a rule further defined by the help of a postposition. The general oblique case, without any defining postposition, is specially employed for the case of the agent. There are also examples of the survival of the old locative and of the old ablative.

In Lahnda the final short vowel of the weak forms has been dropped, but in some cases the final *u* of the masculine and the final *i* of the feminine have been preserved by epenthesis. The

Lahnda forms of the nominative plural and of the various oblique forms are identical with those found in Panjabi. In both languages the accusative case is the same as the nominative, unless special definiteness is required, when the dative is employed in its place. The agent case is the oblique form without any postposition. All the postpositions are added to the oblique form. The genitive is really a possessive adjective and agrees with the person or thing possessed in gender, number and case.

An adjective agrees with its qualified noun in gender, number and case. In Lahnda the only adjectives which change in these respects are strong adjectives in *ā*. In Sindhi weak forms in *u* also change the *u* to *e* or *a* in the feminine. The plural and oblique forms are made as in the case of nouns. If a postposition is used with the noun it is not also used with the adjective. Comparison is effected by putting the noun with which comparison is made in the ablative case. Sometimes special postpositions are employed for this form of the ablative.

The north-western group of Indo-Aryan vernaculars, Sindhi, Lahnda and Kashmiri, made free use of pronominal suffixes. In Kashmiri these are added only to verbs, but in the other two languages they are also added to nouns. These suffixes take the place of personal pronouns in various cases.

All these suffixes are remnants of the full pronominal forms. In all cases they can be at once explained by a reference to the originals in Dardic rather than to those of other Indo-Aryan languages.

Conjugation.—There are, in both languages, two conjugations, of which one (intransitive) has *-a-* and the other (transitive) *-e-* or *-i-* for its characteristic letter. The differences appear in the present participle and, in Sindhi, also in the conjunctive participle, the present subjunctive, and imperative. The two latter are the only original synthetic tenses which have survived in Sindhi, but in Lahnda the old synthetic future is also in common use. Both languages have a passive voice formed by adding *ij* or *īj* to the root. This form is not employed for the past participle or for tenses derived from it.

The past participle of the transitive verb is passive in signification. There is therefore no need of a past participle for the passive voice. The Sindhi present participle of the passive voice follows a different rule of formation, and, in Lahnda, it omits the letter *j*. In other respects the passive is conjugated like a regular verb of the first conjugation. The passive is directly derived from the outer Prakrit passive in *-ijja-*.

The present subjunctive is the direct descendant of the old Prakrit present indicative.

The imperative is formed in the same way. The Sindhi future is formed by adding the nominative pronominal suffixes to the present participle. As there are no nominative suffixes of the third person, for that person the simple participle is employed. There are slight euphonic changes of the termination of the participle in the other persons.

The past tense is formed from the past participle with pronominal suffixes added in both languages. As in the transitive verb the past participle is passive in signification, the subject must be put in the agent case, and the participle agrees in gender and number with the direct object, or, if the object is put in the dative case instead of the accusative, is treated impersonally in the masculine.

There are numerous compound tenses formed by conjugating the verb substantive with one or other of the participles. The past has slightly different forms with a feminine subject. Additional suffixes may be added to indicate the object, direct or remote.

Numerous verbs have irregular past participles, derived directly from the Prakrit past participles. The many compound verbs are formed much as in Hindustani, and must be learnt from the grammars.

Literature.—Sindhi and Lahnda possess no literature worthy of the name. There is, in both languages, a large stock of folk-songs—rude poems dealing with the popular traditions of the country. *See* Colonel Sir Richard Temple's *Legends of the Panjab* (Bombay, 1884–1900). Also E. Trumpp, *Sindhī Literature, the Dīvān of Abd-ul-Latīf, known by the name of Shāha jō Risālō* (Leipzig, 1866).

Bibliography.—G. Stack, *Grammar* and *Dictionary* (both Bombay, 1849); E. Trumpp, *Grammar* (London and Leipzig, 1872); G. Shirt, Udharam Thavurdas, and S. F. Mirza, *Sindhi-English Dictionary* (Karachi, 1879); E. O'Brien, *Glossary of the Multani Language* (1st ed., Lahore, 1881; 2nd ed., revised by J. Wilson and Hari Kishen Kaul, Lahore, 1903); W. St. Clair Tisdall's *Simplified Panjabi Grammar* (1889) also deals in an appendix with Lahnda; T. Bomford, "Rough Notes on the Grammar of the Language spoken in the Western Panjab" in *Journal of the Asiatic Society of Bengal*, vol. lxiv. pt. i. pp. 290 ff. (1895); "Pronominal Adjuncts in the Language spoken in the Western and Southern Parts of the Punjab," *ib.* vol. lxvi. pt. i. pp. 146 ff. (1897); J. Wilson, *Grammar and Dictionary of Western Panjabi as spoken in the Shahpur District* (Lahore, 1899); A. Jukes, *Dictionary of the Jatki or Western Panjabi Language* (Lahore and London, 1900); G. A. Grierson, "Vrācada and Sindhī" in *Journal of the Royal Asiatic Society*, p. 47 (1902); R. T. Turner, "The Sindhī Recursives" in *Bulletin of the School of Oriental Studies*, vol. iii. 301 (1921); "Cerebralization in Sindhī," J.R.A.S. p. 555 (1924); vol. viii. of the *Linguistic Survey of India* contains full particulars in great detail.

SIN-EATER, a man who for trifling payment was believed to take upon himself, by means of food and drink, the sins of a deceased person. The custom was once common in many parts of England and in the highlands of Scotland. Usually each village had its official sin-eater to whom notice was given as soon as a death occurred. He at once went to the house, and there, a stool being brought, he sat down in front of the door. A groat, a crust of bread and a bowl of ale were handed him, and after he had eaten and drunk he rose and pronounced the ease and rest of the dead person, for whom he thus pawned his own soul.

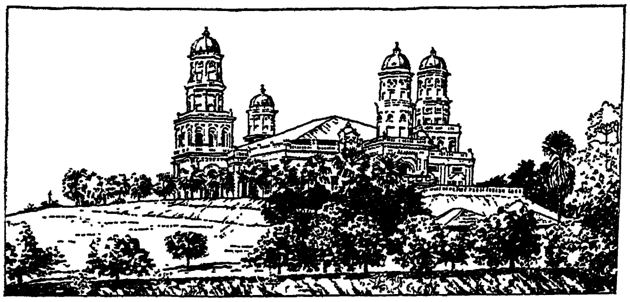
In the earlier form the sin-eater was taken into the death-chamber, and a piece of bread and possibly cheese, having been placed on the breast of the corpse by a relative, usually a woman, was afterwards handed to the sin-eater, who ate it in the presence of the dead. He was then handed his fee and at once hustled and thrust out of the house amid execrations and a shower of sticks, cinders, or other missiles. The custom of sin-eating is generally supposed to be derived from the scapegoat in Leviticus xvi. 21, 22. A symbolic survival of it was witnessed in 1893 at Market Drayton, Shropshire. After a preliminary service had been held over the coffin in the house, a woman poured out a glass of wine for each bearer and handed it to him across the coffin with a "funeral biscuit." In Upper Bavaria sin-eating long survived; a corpse cake was placed on the breast of the dead and then eaten by the nearest relative.

SINEW, a tendon, a cord-like layer of fibrous tissue at the end of a muscle forming the attachment to the bone or other hard part. The broad, flat tendons are usually called *fasciae* (*see* Muscular System and Connective Tissue).

SINGAPORE, a town and island situated at the southern extremity of the Malay peninsula in 1° 20′ N., 103° 50′ E. Singapore is the most important part of the crown colony of the Straits Settlements, which consists with it of Penang, Province Wellesley and the Dindings, and Malacca (*qq.v.*). The port is one of the most valuable of the minor possessions of Great Britain, as it lies midway between India and China, and forms the most important halting-place on the trade-route to the Far East. It is being strongly fortified as a naval base at the cost of the imperial government, aided by an annual military contribution payable by the colony and fixed at 20% of its gross revenue. Its geographical position gives it strategic value; and as a commercial centre it is without a rival in this part of Asia. Its prosperity has been greatly enhanced by the rapid development of the Malay States on the mainland. It possesses a good harbour with docks and extensive coaling-wharves, which were acquired by government from the Tanjong Pagar Dock Company. It is also resorted to by native craft from all parts of the Malay archipelago. On the island of Pulau Brani stand the largest tin-smelting works in existence, which for many years have annually passed through their furnaces more than half the total tin output of the world. Singapore has also establishments for tinning pineapples, a rubber factory, a tannery, a shoe factory and a biscuit factory. Notable are a few large commercial buildings, government house, the law-courts, a magnificent hospital, a new lunatic asylum, Raffles college, Raffles museum and the cathedral of St. Andrew. There are

several Roman Catholic churches, a Free Kirk, an American mission, and chapels belonging to Nonconformist sects. The mosques and Chinese and Hindu temples are numerous. There are military barracks at Tanglin. There is a good race-course and polo-ground, a fine cricket-ground on the esplanade, four golf courses, and yachting, swimming and social clubs.

The island is 27 m. long by 14 m. broad, and is joined to the state of Johore, situated on the mainland of the Malay Peninsula, by a cause-way. A railway runs from the town of Singapore



BY COURTESY OF THE CANADIAN PACIFIC STEAMSHIP CO.

THE MOSQUE OF THE SULTAN OF JOHORE, ONE OF THE MANY RELIGIOUS EDIFICES IN SINGAPORE

through Johore Bharu up to Penang and on to Bangkok. The strait which divides the island from the Dutch islands of Bintang, Rhio, etc., bears the name of the Singapore strait. The surface of the island is undulating and diversified by low hills, the highest point being Bukit Timah, on the north-west of the town, which is a little over 500 ft. Geologically, the core of the island consists of crystalline rocks; but in the west there are shale and sandstone. All round the island the valleys are filled with alluvial deposits on a more extensive scale than could have been formed by the existing rivers: they suggest that the island was once united to Johore. The south-west shores are fringed with coral reefs, and living coral fields are found in many parts of the straits. Composed largely of red clays and laterite, the soil is not rich, and calls for the patient cultivation of the Chinese gardener to make it productive. The forest is of a mean type. The humid climate causes the foliage here, as in other parts of Malaya, to be luxuriant, and the contrast presented by the bright green and the rich red laterite of the cliffs is striking. When first occupied by Sir Stamford Raffles, on behalf of the East India Company, the island was covered by jungle, but now all the land not reserved by government has been taken up, principally by Chinese, who plant rubber, vegetables and other products. There are fine botanical gardens at Tanglin.

The climate of Singapore is humid and hot. There is hardly any seasonal change, and the dampness causes the heat to be more oppressive than are higher temperatures in drier climates. The mean temperature in Singapore during 1926 was 80·1° F. The highest shade temperature for the year was 93·5° F registered in April; the lowest 70·7° F, registered in February. North and north-east winds prevail from the middle of October to the end of April, and south and south-west winds from the middle of May to the end of September. The rainfall has been recorded regularly since 1862. The wettest year was 1913 with 3,442·37 mm. and the driest 1877 with 1,482·7 mm. The average number of rainy days during the past decade has been 173 and the average rainfall 2,526·7 mm.

Statistics of population are given in the article STRAITS SETTLEMENTS: *Population.* Singapore with its hordes of immigrants naturally has the lowest proportion of females but it is rapidly making up leeway. There are representatives of almost every Asiatic nation and of many other races, Singapore being one of the most cosmopolitan cities in the world.

As Singapore is the chief administrative centre of the colony, the governor has his principal residence here. Here also are chief offices of the various heads of the government departments, and here the legislative council of the colony holds its sessions.

The trade of Singapore is chiefly dependent upon the position which the port occupies as the principal emporium of the Federated Malay States and of the Malay archipelago, and as the great port of call for ships passing to and from the Far East. The ships using the port during 1926 numbered 15,977 with an aggregate tonnage of 25,628,329 tons of which 7,516 were British ships with an aggregate tonnage of 10,977,421 tons. The retail trade of the place is largely in the hands of Chinese, Indian and Arab traders, but there are good European shops. The port is a free port, import duties being payable only on opium, tobacco, wines and spirits.

It is possible that Singapore was a trading centre in the 12th and 13th centuries, but neither Marco Polo nor Ibn Batuta, both of whom wintered in Sumatra on their way back to Europe from China, have left anything on record confirmatory of this. About the middle of the 14th century it was destroyed by Majapahit. In 1552 St. Xavier despatched letters from the port to Goa. When it passed by treaty to the East India Company in 1819, Sir Stamford Raffles persuading the sultan and temenggong of Johore to cede it to him, it was uninhabited save by fisherfolk. It was at first subordinate to Benkulen, the company's principal station in Sumatra, but in 1823 it was placed under the administration of Bengal. It was incorporated in the colony of the Straits Settlements when that colony was established in 1826. *See* also MALAY PENINSULA and STRAITS SETTLEMENTS. For the naval base *see* DOCKS AND NAVAL BASES and DOCKS.

(Singapore, 1902). (H. CL.)

SINGER, SIMEON (1846–1906), Jewish preacher, lecturer and public worker, was born in London. In 1867 he became minister of the Borough Synagogue, London. He moved to the new West End Synagogue in 1878, and remained the minister of that congregation until his death. Singer was a power in the Jewish community in the direction of moderate progress; he was a lover of tradition, yet at the same time he recognized the necessity of well-considered changes. In 1892 at his instigation the first English conference of Jewish preachers was held, and some reforms were then and at other times introduced, such as the introduction of Bible readings in English, the admission of women as choristers and the inclusion of the express consent of the bride as well as the bridegroom at the marriage ceremony. Singer did much to reunite Conservatives and Liberals in the community, and he himself preached at the Reform Synagogue in Manchester. His most famous work was his new edition and English translation of the *Authorized Daily Prayer Book* (first published in 1870), a work which has gone through many editions.

See *The Literary Remains of the Rev. Simeon Singer* (3 vols., 1908), with Memoir.

SINGER MANUFACTURING COMPANY, THE, dates its founding from the invention and marketing of the first practical sewing machine by Isaac Merritt Singer in 1851. The first few machines were produced in a small shop in Boston, Mass. A partnership with Mr. Edward Clark was formed soon afterward under the name of I. M. Singer and Company, from which date the rapid expansion of the business began. In 1853 a factory and main office were established in New York. In 1863 the co-partnership was merged into a corporation, The Singer Manufacturing Company (of New York), which in 1873 became a New Jersey corporation under the same name.

The first large modern factory was established at Elizabethport, N.J., in 1872. In 1929 there were nine factories for the manufacture of Singer machines situated in four countries and employing 27,000 persons. In addition to sewing machines for household use the Singer Company early began the development of specialized sewing machines for industrial purposes and in 1928 made more than 3,000 different machines for stitching a wide variety of products. In 1889 the company originated the electric sewing machine and this modern type is now in general use. Export business received close attention from the beginning.

The capital structure of the present company is 900,000 shares of capital stock, all of one class, of the par value of $100 each.

(C. C. F.)

SINGHBHUM, a district of British India, in the Chota Nagpur division of Behar and Orissa. The administrative headquarters are at Chaibasa. Area 3,879 sq. miles. Pop. (1921), 759,438. Singhbhum is a hilly district on the fringe of the Chota Nagpur plateau with mountains in the north-west rising to a height of 2,500 ft., and in the south-west, where they are called the Saranda hills, to nearly 3,000 feet. The central portion consists mainly of well-cleared open country, which is the most fertile tract in the district. The south is another undulating plateau. The eastern portion of the district, which bears the name of Dhalbhum, contains the valley of the Subarnarekha, the principal river. The north-west is included in the estate of Porahat (800 sq.m.), while the central and south-western portions comprise the Government estate of the Kolhan with an area of nearly 2,000 sq. miles. Over one-third of Singhbhum is covered with primaeval forest, containing valuable timber trees; in the forests tigers, leopards, bears, bison and deer are found.

Nearly two-thirds of the inhabitants belong to aboriginal tribes, among whom the Hos, meaning simply "men," are predominant. Their warlike character won for them the name of Larka, or fighting, Kols among outsiders. They were not finally subjugated till 1836, when the Kolhan was brought under British rule. In Porahat they broke out in rebellion during the Mutiny, and after a long campaign submitted in 1859.

During recent years Singhbhum has become one of the most important industrial tracts in Behar and Orissa, largely owing to the establishment of the works of the Tata Iron and Steel company and of subsidiary concerns at Jamshedpur (*q.v.*), and in its neighbourhood. The exploitation of its mineral resources has begun and has great potentialities. The deposits of iron ore in the Saranda hills, which are reputed to be among the finest in the world, supply material to large works near Asansol, in Bengal. The output of iron ore in 1925 was nearly half a million tons. There is a belt of copper extending for about 80 m., where mining has been in operation for many years. Other mineral resources include chromite, manganese ore, apatite and gold: 6,000 ounces of the last were produced between 1915 and 1919. Several companies have also been formed for the production of silica bricks, fire-bricks and pottery, for which materials are obtained north-east of the mineral area. Timber is obtained from the forests, a minor product of which is *sabai* grass for the manufacture of paper, ropes and string.

SINGING. Like other arts, singing has had its periods of development, culmination and decay. It reached its highest point towards the end of the 18th century, since which time the development of music—largely in relation to the orchestra—has led composers to a relative neglect of the voice as an instrument to be studied on its own account.

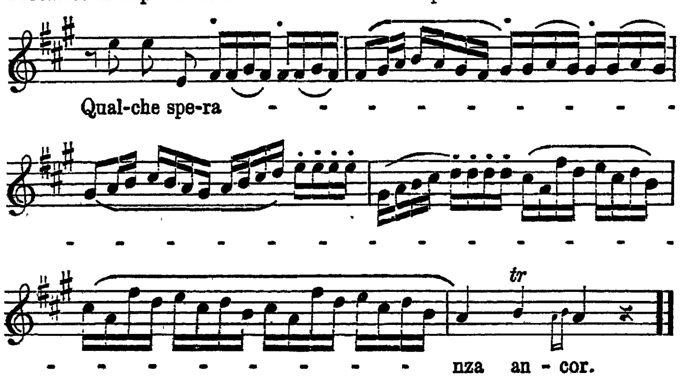
In its highest sense we must regard singing as the art of emitting the voice in fulness, unerringly on the pitch, so that each word is prolonged as naturally as during the most expressive talking. Such a standard demands a special mode of controlling the breath in order that the voice, issuing in freedom and with openness of throat, can be sustained and intensified.

Any language, whose practice is to dwell on the vowels and to avoid throaty combinations of consonants, must tend towards sonority of speech and freedom of throat. We are indebted to the "Land of Song" for the art of *bel canto,* or beautiful singing. To copy the haunting purity of the vowels as sung by Italian artists has ever been the longing and despair of other nations. It may well be that such purity was originally developed through the singers having to sustain, in large cathedrals, the long phrases characteristic of the music of Palestrina (b. 1514).

Unfortunately it was not the habit of the old masters to publish books on their art. He who would form a *bel canto* of the vowels of his own country must rely mostly on the sayings or maxims of the old singers which have been handed down, and show their attitude towards singing and their ideas relative to its cultivation. Of especial interest is Angelo Bontempi's description of the plan of studies at the Papal School at Rome (about 1624). Assembled in class, the pupils practised, for one hour daily, exercises on richness of tone; a second hour was devoted to the "trill"; a third hour to rapid passages; finally, one hour to the cultivation of taste and expression. All this was done in the presence of a professor who saw that the pupils sang before a looking glass so as to learn to avoid grimaces: wrinkling of the brow, winking of the eye-lids, or distortion of the mouth. The richness of these voices was undoubtedly assisted by extreme caution in the selection of studies, always kept within the natural compass of the voice.

It is to the credit of the early English composers, Byrd, Morley, Dowland and Lawes (1550 to 1650) that they wrote songs demanding sustained power. Purcell (b. 1658) composed his touching "Dido's lament" also songs demanding execution, such as "Let the mighty engines." In Italy, celebrated composers for the voice were Carissimi (b. 1604), Alessandro Scarlatti (b. 1659), Lotti (b. 1667) and Bernacchi (b. 1690); the latter was engaged by Handel to sing in his opera "Rinaldo."

Porpora (b. 1686), a pupil of Scarlatti, established a school of singing, whence issued those wonderful singers Farinelli and Caffarelli. The latter, who was kept to one sheet of exercises for five years, excelled in slow and pathetic airs. He was unapproachable in beauty of voice and in the execution of the trill. Farinelli became possibly the most remarkable singer who ever lived. Porpora's airs and exercises are mostly directed to flexibility of the voice; they are of such difficulty as to be almost impossible of execution by singers of the present day. Here for instance is a portion of an aria from his opera "Siroc":



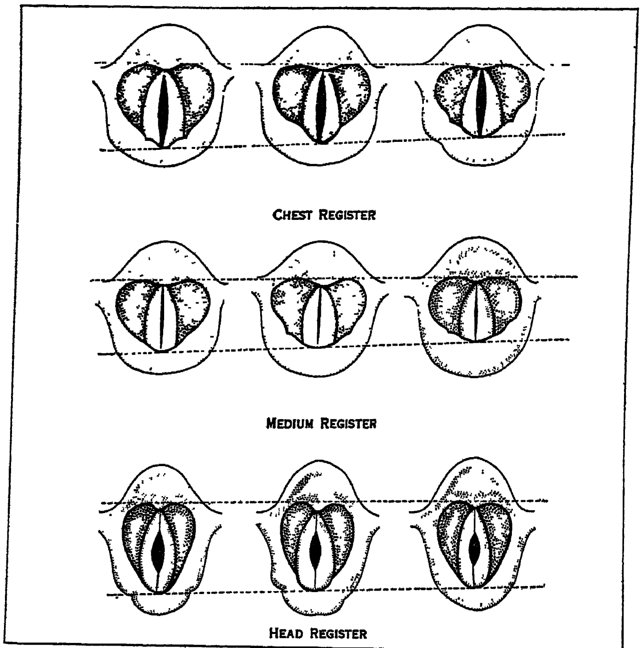
The noble music of Handel, Bach and Gluck was performed with masterly ease and expression by singers of this period. As time passed, the purity of style of the operas of Mozart (b. 1756) and Cherubini (b. 1760) became overshadowed by lovely melody, admirably adapted for the display of the voice. Rossini (b. 1792), Donizetti (b. 1797), and Bellini (b. 1801), composed the delightful music which was sung by such famous artists as Malibran, Grisi, Rubini, Tamburini, Lablache and Jenny Lind. The singing of Mozart's aria "L'amerò" by Jenny Lind was a notable achievement. Later two of the most famous of English singers, the tenor Sims Reeves and the baritone Santley rose to fame in England after completing their studies in Italy. And about the same time Francesco Lamperti of Milan, as the master of Italo Campanini and Albani, became noted as a teacher of *bel canto.*

Some time afterwards the whole question of singing and singing teachers became one of general interest and discussion. Books by Mandl of Paris, Morell Mackenzie, Lennox Browne and others described the anatomy and action of the vocal organs. Professors of singing also wrote about their different methods. Possibly, owing to the surgeons not being singers, or the singing masters not being clear in their physiology, little came of this. About this time too, through the genius of Wagner, the increase in the power of the orchestra reached its climax; and a corresponding increase of sonority on the part of the singers became necessary.

To members of the "old guard" such became possible. When, however, these experienced ones were replaced by younger and sometimes half-trained singers, serious decadence in the art was observed. There seemed occasionally a struggle between the voice

and the orchestra which was not conducive to a feast of *bel canto.* Lamperti attributed this decadence to the quality of the music being no longer suitable to the voice. The composer Verdi, deploring the absence of purity and expressive phrasing, declared that singers must return to the methods of the old masters.

The tendency of modern singing is to arrest the breath by a rigid contraction of the parts which should be free to form the



FROM "PLAIN WORDS ON SINGING" (WM SHAKESPEARE; PUTNAM SONS, LTD.)
DIAGRAM SHOWING THE UNCONSCIOUS SHORTENING OF THE VOCAL CORDS DURING SINGING

tone and pronunciation. The achievement of the old singers was to breathe silently and to control the breath while emitting the voice through the open throat. Lablache, when asked how Rubini breathed, answered "although I sang a duet with him I could not discern *when* or *how* he breathed." Pacchierotti wrote "He who can control the breath and sustain the vowels with the throat open, knows well how to sing." Crescentini added "Singing consists of freedom about the neck and the voice resting on the breath."

Here we will make enquiry into the *tone* of the voice, and the importance of the freedom of spaces in the mouth. An admirable practice for realising the shape of the tone spaces is that of slowly whispering the vowels. As the vocal cords are not in action, nothing distracts the attention from the pronunciation or the breath. After having whispered, the throat feels much more open when we start singing the same vowels. Donders of Utrecht noticed that the vowels, when quietly whispered, caused the air in the mouth to resound at different pitches. Dr. William Aikin has determined the exact pitch of the English vowels, so that these, when correctly whispered, cause a musical scale to be distinctly heard.

Any man by sustaining "Ah" in a whisper and tuning this whisper to the note C (an octave above the third space, treble clef) will realise the greatest resonance possible to that vowel, and a remarkable sense of openness at the back of the tongue. This being undeniable, the following conclusions are worthy of careful consideration: 1. By correctly tuning a whispered vowel, we realise the openness of the throat which we must attain during singing. 2. The vocal cords being so near the base of the tongue, their natural action is dependent on the freedom of the tongue. 3. Freedom of throat and tongue sets up in turn freedom of the soft palate, lips, face and eyes. 4. Throaty, gloomy, nasal or "white" sounds are impossible in that open state of throat by which we correctly tune the vowels.

In the following whispered scale, the pattern words contain the vowel sounds, which only are to be whispered, the consonants being ignored. By reason of their smaller tone cavities, the whispers of women tune a minor third higher than those of men. The pattern sentence suggested is:—*Who would know aught of art must learn and then take his ease.*

A	man	whispering	"who"	should	sound	F,	but	a woman	A♭
"	"	"	"would"	"	"	F♯,	"	"	A
"	"	"	"know"	"	"	G,	"	"	B♭
"	"	"	"aught"	"	"	A,	"	"	C
"	"	"	"of"	"	"	B,	"	"	D
"	"	"	"art"	"	"	C,	"	"	E♭
"	"	"	"must"	"	"	D,	"	"	F
"	"	"	"learn"	"	"	E,	"	"	G
"	"	"	"and"	"	"	F,	"	"	A♭
"	"	"	"then"	"	"	G,	"	"	B♭
"	"	"	"take"	"	"	A,	"	"	C
"	"	"	"his"	"	"	B,	"	"	D
"	"	"	"ease"	"	"	C,	"	"	E♭

We must now realise that we cannot tune the voice by anything we see or feel. We have no direct control over the action of the vocal cords. Many people, when given a note on the pianoforte, are at first all at sea as they try to sing that note. It is only by employing the right mechanism that the voice can tune unconsciously in the very "eye" of the note intended. So it is only by alertness in listening to the tune that the right mechanism can be attained. The accompanying illustration from "Plain words on Singing," by William Shakespeare, shows the unconscious shortening of the vocal cords, which occurs in the different registers.

Giuglio Caccini (b. 1558) maintained that "the first and most important foundation is how to start the voice in every register; not only that the intonation be faultless, but that the quality of the tone be preserved." Agricola (b. 1720) says "Many singers, before reaching a higher note, cause several others to be heard, with the result described as 'seeking the note' or scooping up to it." It is impossible to sing with the tongue rigid, and at the same time, with the throat open. The art of singing lies in the avoidance of rigidity and the adoption of the open throat.

The advantage of the practice of whispering long vowels will now be realised. The pressure which sends *out* the breath is felt below the waist, while just above is realised a simultaneous *hold-back* of the breath. The hold-back must not let the send-out gain the mastery or the result will be wasted. While singing, the breath-feeling should be the same as during whispering. Jean de Reszke declared that "right singing depends on the hold-back of the breath." We realise with every good note a sensation as of "warming" some object; while the freedom of throat should be as of "yawning." The notes of the scale then join as "pearls on a string," the string being the breath.

Johannes Hiller (b. 1728) describes the "legato" as "consisting of no gap in passing from one note to another." Johann Micksch (b. 1765) says: "The first study in training the voice is how to use the breath sparingly, never becoming breathless, by retaining some breath in reserve. Loud singing first becomes beautiful by rightly singing piano. The notes must be drawn out, never pushed out; and taken so quietly that one may produce with the least breath a note that will gradually swell to the loudest degree and again die away. Tone is the material of all music. It has as much variety as the human countenance."

Manstein (b. 1790) says: "It does not matter how *much,* but *how* we sing. By practice, art becomes second nature. The experienced artist, after long continued study, thinks not of the manner and means of execution but devotes himself to expression, with the aim of touching the innermost soul." Lamperti (b. 1813) averred that "The eye is the mirror of the soul." It is impossible to express at the same time joy in the eye and sorrow in the voice. J. A. Hiller previously named said: " 'Well spoken, is half sung' is a motto which should be inscribed on the four walls of every school."

The old style caused every vowel and consonant to be clearly enunciated. At the present day, owing possibly to the heavy orchestration, and the music of Wagner and the modern Italian composers, there is frequently difficulty in understanding the words, and sometimes in deciding even in what language the opera is given. Sonority of voice is not incompatible with richness of tone. Audiences are becoming critical over the quality of expression of the singers. They long for the *bel canto* which once carried sounds of living emotion to the far corners of the theatre.

The composer Ferdinand Hiller, writing about Rubini the tenor, said: "the sonority and overpowering beauty of his high notes combined with unerring precision in attack, thrilled all hearts. In dexterity of execution he excelled the most famous instrumentalists. Further, he had the most distinct pronunciation. Above all, however, a truly electrifying capability of expressing every shade of feeling, the sigh of pure devotion, the distress of the forsaken, the blissful agitation of the happy. Indeed, I believe he could have made all these immutable themes of the loving heart tell on his audience, while singing the simple scale." This is indeed, a summary of the Art of Singing. (W. Sha.)

SINGLE SIDE BAND TRANSMISSION is the method of radio transmission by which one side band (or group of frequencies) is transmitted and the other is suppressed. The carrier wave may be either transmitted or suppressed.

SINGLE-STICK, a slender, round stick of ash about thirty-four inches long and thicker at one end than the other, used as a weapon of attack and defence, the thicker end being thrust through a cup-shaped hilt of basket-work to protect the hand. The original form of the single-stick was the "waster," which appeared in the 16th century and was merely a wooden sword used in practice for the back-sword (*see* Sabre-Fencing), and of the same general shape. By the first quarter of the 17th century wasters had become simple cudgels provided with sword-guards, and when, about twenty-five years later, the basket-hilt came into general use, it was employed with the cudgel also, the heavy metal hilt of the back-sword being discarded in favour of one of wicker-work. The guards, cuts and parries in single-stick play were at first identical with those of back-sword play, no thrusts being allowed (*see* Fencing). The old idea, prevalent in England in the 16th century, that hits below the girdle were unfair, disappeared in the 18th century, and all parts of the person were attacked. Under the first and second Georges back-sword play with sticks was immensely popular under the names "cudgel-play" and "single-sticking," not only in the cities but in the country districts as well, wrestling being its only rival. Towards the end of the 18th century the play became very restricted. The players were placed near together, the feet remaining immovable and all strokes being delivered with a whip-like action of the wrist from a high hanging guard, the hand being held above the head. Blows on any part of the body above the waist were allowed, but all except those aimed at the head were employed only to gain openings, as each bout was decided only by a "broken head," *i.e.* a cut on the head that drew blood. At first the left hand and arm were used to ward off blows not parried with the stick, but near the close of the 18th century the left hand grasped a scarf tied loosely round the left thigh, the elbow being raised to protect the face. Thomas Hughes's story, *Tom Brown's School Days,* contains a spirited description of cudgel-play during the first half of the 19th century. This kind of single-sticking practically died out during the third quarter of that century, but was revived as a school for the sabre, the play being very much the same as for that weapon. The point was introduced and leg hits were allowed. By the beginning of the 20th century single-stick play had become much neglected, the introduction of the light Italian fencing sabre having rendered it less necessary. Stick-play with wooden swords as a school for the cutlass is common in some navies. (X.; A. R. H.)

SINGLE TAX. The name given by Henry George, the American economist, to the doctrine of levying a tax upon rent alone as the sole necessary instrument of taxation. Land, he held, is the true source of wealth, and therefore the only proper revenue of a state is that derived from the appropriation of rent. The doctrine is one with that of the Physiocrats, the school of French economists founded by Quesnay (1694-1774). The "impôt unique" of Quesnay was proposed in days when the produce of the soil constituted by far the greater part of any nation's wealth. Henry George wrote his *Progress and Poverty* in 1879, when already the arts of industry were playing a dominating part in wealth production, and when capital was accumulating in great aggregations. Nevertheless, he believed that profits and industry should remain untaxed. He went further, and appeared to believe that, under a single tax system, all economic problems would be solved.

The essence of the single tax theory may be given in Henry George's own words, taken from his book, *The Condition of Labour,* written in 1891: "We have no fear of capital, regarding it as the natural handmaiden of labour; we look on interest itself as natural and just; we would set no limit to accumulation, nor impose on the rich any burden that is not equally placed on the poor; we see no evil in competition, but deem unrestricted competition to be as necessary to the health of the industrial and social organism as the free circulation of the blood is to the health of the bodily organism—to be the agency whereby the fullest co-operation is to be secured. We would simply take for the community the value that attaches to land by the growth of the community; leave sacredly to the individual all that belongs to the individual; and, treating necessary monopolies as functions of the State, abolish all restrictions and prohibitions save those required for public health, safety, morals, and convenience."

This declaration is the more striking because it was written in answer to a Papal Encyclical on the labour question, which advocated the protection of labour and especially the labour of women and children. The single tax, Henry George thought, would make all, or nearly all, industrial legislation unnecessary.

The fundamental doctrine underlying the proposal was that all men are equally entitled to the use of the land. As, however, the management of the land by the State was impossible in practice, and as it was also impossible to divide it up into equal parcels, or into parcels of equal productivity, the road to justice was to leave the land in private ownership, and to appropriate the "economic rent," thus leaving to the owners the value of their own improvements. Collecting the economic rent as a social surplus by the single tax, the community as a whole would receive justice while individual enterprise would not be fettered. Universal free trade and free competition were thus postulated as parts of the doctrine. Private property was to be sacred as never before, for it was to go scot free of all taxation. The millionaire manufacturer was to pay no more in taxes than his poorest clerk.

It was thus implied that the yield of the single tax would be sufficient to meet the expenses of government. This might easily be so in an agricultural community, but in Great Britain in 1928 the entire economic rent of the land in town and country would not defray more than a small fraction—perhaps one-eighth—of the expenses of the central and local governments.

(*See* George, Henry; Physiocratic School; Economics; Rent; National Expenditure.)

SINGLETON, the oldest town of the Hunter River valley, in central eastern New South Wales, Australia, socially and industrially one of the most interesting and important areas in the southern hemisphere. In its many-sided significance—in respect of its site in the river valley liable to floods, the presence of coal and possibly of petroleum in its neighbourhood, grazing and timber-cutting, mixed agriculture, fruit and vine-growing, co-operative dairying and buttermaking, cattle-marketing—it typifies the historical and economic growth of the area in which it occupies a central and linking position. From the coast round about Newcastle the Hunter valley stretches north-west as a low narrow trough between the northern and southern plateaux for about 120 miles to a saddle near Cassilis (alt. 1,500 ft.) which barely divides its drainage from that of the western rivers (Talbragar-Macquarie). It falls into two main sections (i.) the upper Hunter-Goulburn drainage basin, an irregular hill-and-valley country (7,000 sq. miles; av. elevation 1,000 ft.) with streams descending chiefly from the northern heights, and divided by a constriction (Branxton Gap, 10 miles wide, just below Singleton) from (ii.) the lower, partly deltaic and estuarine valley. Tributaries (Paterson and Williams Rivers) open up important valleys in the north-east and help to extend the lowland northwards from Newcastle. The basalt capping of the north-west and north-east plateaux have supplied rich alluvials to the river floors but the southern sandstone scarps are poor in water and generally infertile. Relief, and the position upon the transition zone between summer and winter rains, help to give the upper basin a drier climate (22–30

in.) with a greater range of temperature (Cassilis: av. ann. temp. 72°–47·5° F; mean daily range, 24·4° F; av. ann. rainfall 21·3 in.), and to the lower basin more humid and equable conditions (Newcastle: 72°–55° F; 15°; 42 in.). In general, also, much more rain falls on the northern slopes than on the southern. In the upper basin the rougher margins supply timber and grazing grounds, and, though good soil abounds, erratic rainfall encourages cattle, sheep and horse rearing (*e.g.,* Scone district) and saw-mills are widely distributed. Nearer the centre, the valleys—which would admit of irrigation—are being invaded by mixed farming, and large holdings are decreasing in number. At Aberdeen is a large meat (mutton, beef, rabbit) freezing works and at Denman a large butter factory serves the growing dairying industry. Here also the physical conditions are favourable for growing cotton. The middle Hunter valley, formerly and still to some extent in pastoral occupation, was devoted to wheat-growing, arable mixed-farming and fruit-growing (citrus and stone fruits, vines), but latterly increasingly to dairying. Thus around Singleton large estates, and also timber-cutting, persist, but farming, fruit-growing, and, most recently, dairying have increased and Singleton is a notable butter-making centre. Fruit is extensively grown in the Paterson and Williams valleys but the wine-making industry, once important, has declined. The disappearance of wheat as a grain crop has been largely due to the humidity of the climate. From and through the Hunter valley come the horses, cattle, meat (*cf.* the famous Maitland cattle-market), and also the agricultural and dairy produce of the valley itself and of the western slopes (Liverpool Ranges). But whereas the markets were formerly chiefly in Sydney or overseas, ever larger proportions have been absorbed by the growing coal-mining and industrial population at hand. All three measures of the State's main coal deposit crop out in the Hunter valley. The most important seams are those of the Newcastle field (Newcastle or Upper Measures), of the Maitland field—mainly Lower (Greta) seams—and those of Muswellbrook (Upper and Lower). The known reserves within the area are estimated at 12,000,000,000 tons, the total possible reserves at 72,000,000,000 tons (Newcastle field: 270,000,000 tons available; S. Maitland field: 1,350,000,000 tons; Muswellbrook: 96,000,000 tons of Lower, besides large reserves of Upper Series coals). Comparative ease of working and access to the sea have made this the chief coal-exporting area of Australia, but from various causes, social as well as economic, the coal industry is severely depressed, the annual output—normally 10,000,000 tons—has greatly declined, and the export trade has at present almost ceased. Output, 1926: northern field: 7,258,000 tons (£6,835,000); *cf.* southern field (*see* BULLI, PORT KEMBLA): 2,025,000 tons (£1,661,000); western field (*see* LITHGOW): 1,604,000 tons (£941,000). The rise of manufacturing industry—notably that of the steel industry with its associated chemical and metallurgical industries—tends to place mining in the second rank and to substitute an industrial for a mining population, though a recent (1929) project for the large-scale (£3,000,000 capital) distillation of the Ellalong (Cessnock; *see* MAITLAND) coal reserves holds out promise for the future of the coal, as well as of other industrial developments.

Newcastle, with its satellites, is the chief industrial area and also the chief port of the valley, but the S. Maitland field (W. Maitland-Cessnock) is now the chief coal-producing area, while Muswellbrook (pop. 2,400), a farming centre in the upper Hunter valley, has a rising coal production. A branching system of railway lines and of roads serves the valley; the river, though navigable to Morpeth (35 miles from the sea), is little used because of its erratic flow. Newcastle provides a not altogether satisfactory harbour and Port Stephens has been suggested as a more desirable outlet. Interesting also is the suggestion for linking the valley by rail with the western system over the Cassilis gap. Population has grown rapidly and now amounts, in the whole valley, to *c.* 225,000. It is mainly an urban population, the Newcastle-Cessnock-Maitland agglomerations alone including some 150,000. Some of the most difficult problems of Australian economic and political life have been introduced during the evolution of this valley which typifies the present stage of growth of the Commonwealth. (*See* F. R. E. Mauldon: *A Study in Social Economics, The Hunter River Valley,* 1927.) (*See* also NEWCASTLE, MAITLAND.)

SINGORA or **SONGKLA** (the *Sangore* of early navigators), a port on the East coast of the Malay peninsula and the headquarters of the high commissioner of the Siamese division of Nakhon Sri Tammarat. It is situated in 7° 12′ N. and 100° 35′ E. It was settled at the beginning of the 19th century by Chinese from Amoy, the leader of whom was appointed by Siam to be governor of the town and district. Having been more than once sacked by Malay pirates, the town was encircled, about 1850, by a strong wall, which, as both Chinese governors and Malay pirates are now things of the past, supplies the public works department with good road metal. The population, about 5,000, Chinese, Siamese and a few Malays, is stationary, and the same may be said of the trade, which is all carried in Chinese junks. The town has become an important administrative centre; good roads and the railway connect it with Kedah and other places in the peninsula, and the mining is developed in the interior. In 1906 railway surveys were undertaken by the government with a view to making Singora the port for S. Siam; but this harbour, formed by the entrance to the inland sea of Patalung, would require dredging to be available for vessels of any size.

SINGPHO. The term used in Assam for the tribe called "Chingpaw" or Kachin (*q.v.*) in Burma.

SINHA, SATYENDRA PRASSANO, 1ST BARON OF RAIPUR (1864–1928), Indian statesman, was born of an ancient family of the Kayashta or writer caste in the village of Raipur, Birbhum district, Bengal, in June 1864. From the Presidency college, Calcutta, he went to London in 1881 to join Lincoln's Inn, where he won many prizes and scholarships, and was called to the bar in 1886. On his return to India he at once began to plead before the high court in Calcutta. In 1903 he became standing counsel to the Government. He was the first Indian to be appointed advocate-general of Bengal (1908), and the first to become a member of the Government of India. He held the law portfolio from April 1909 to Nov. 1910. He then resumed his lucrative practice at the bar. He presided at the Indian National Congress session at Bombay in 1915; in his presidential speech he begged the British Government to declare their policy with regard to the development of constitutional government. He and the Maharaja of Bikaner were the first Indians to participate in Empire deliberations in London, for in 1917 they jointly assisted the secretary of State at the meetings of the Imperial War Cabinet, and were members of the Imperial War Conference. Sinha joined the Bengal executive council in the same year, but returned to England in 1918 as a member of the Imperial War Cabinet and Imperial War Conference, subsequently becoming a representative of India at the Peace Conference.

Knighted in 1914, in 1918 he was made K.C., a distinction not previously conferred upon a barrister of Indian birth or practice. At the beginning of 1919 he joined the Lloyd George ministry as under-secretary for India, being raised to the peerage as Baron Sinha of Raipur and made a member of the privy council. He skilfully conducted the Government of India act, 1919, through the House of Lords. At the close of 1920 he was appointed governor of Behar and Orissa, being the first Indian to preside over a British province. Ill-health prevented him from serving his full term in that office, and in 1921 he resigned. In 1926 Sinha was appointed a member of the judicial committee of the privy council. He was opposed to the setting up of the statutory commission on the Government of India at an earlier date than that indicated in the Government of India act, 1919, in view of the divided state of India; but, the decision once taken, he supported the Simon Commission, and entertained its members at Calcutta. He died on Mar. 5, 1928.

Sinha is remembered by Indians as the first to break down all the barriers against Indians, and by lawyers as a learned, patient and courteous judge. Circumstances drove him into politics but his real interests, which he served whenever opportunity offered, lay in the progress of education.

SIN KIANG, or the "New Territory," is a great region west-north-west of China. Area (approx.), 550,340 sq. miles. Pop. (approx.), 1,200,000. It is bounded on the north-east by the

foothills of the Altai mountains, on the east by Outer Mongolia, Kansu and Kuku Nor, on the south by Tibet, on the south-west by the Karakoram mountains and the Pamirs, on the north-west by a portion of the Tien-shan, from which the boundary diverges northward along various heights till it reaches the hills south of the Irtish, and then turns eastward. The Tien Shan range extends through the middle from west to east, and divides the province into two distinct regions. North of it are the districts of Ili (*see* KULDJA) and Dzungaria, the latter of which is also partly in Outer Mongolia. South of the Tien Shan lies the basin of the Tarim river (*q.v.*), bounded on the south by the Kunlun mountains (*q.v.*), beyond which the province stretches to the Karakoram mountains (*q.v.*). The southern extension of the province between these two ranges is the plateau of inland drainage called Chang-T'ang. Dzungaria is a basin depression, the only part of the Chinese region north of the Tien Shan which is, in places less than 1,000ft. above sea-level. The Borotala here drains eastward into Ebi Nor. It has a remarkably heavy summer rainfall, so that the pastures on the hillsides are rich, while the slopes of the Dzungarian Alatau, on the north, are heavily forested. This depression has been drained as a zone through which peoples have moved throughout history. Beyond the hills of its south-west border lies the well forested Ili valley, containing the town of Kuldja and flanked on the south by the Tien Shan. The Tarim basin is an area of internal drainage more than 2,500ft. above sea-level, and to the north-east lies the Turfan depression, the bottom of which is said to be more than 400ft. below sea-level. The slopes from the Kunlun down to the Tarim basin are remarkably sharp in many places, and the southern part of the basin is known as the Takla Makan desert (*q.v.*). The western end of the Tarim basin leads to a pass between the Tien-shan and the Pamirs from Kashgar (*q.v.*) to Bukhara. East of the Takla Makan desert is the lake-marsh region of Lop Nor.

The climate is intensely continental, with average July temperatures in the Tarim basin varying from 69° F at Yangi-Kul, on the Tarim, to nearly 90° in the Turfan depression. The January average temperatures in the Tarim basin vary from 21° at Yarkand to 9·5° at Yangi-Kul. On the higher lands the variation of temperature within a day may be nearly 55°; in the Turfan depression it rarely exceeds 30°. The winds in the Kuen-lun region blow down the mountain slopes in the morning at great velocity, and they die down towards evening. The rainfall in many places in the Tarim basin is less than 2in. for the year, but may rise to 10in. in localities on heights facing west. Much of the Tarim basin has a temperature below freezing point for at least three months. In Dzungaria the temperatures are lower both in summer and winter, and in the Borotala the rainfall is much higher. On the high mountains the precipitation may be considerable.

A great deal of the region is desert, with salt accumulations in many of its depressions. Tamarisk and reed grow here and there are many groups of poplar trees at the foot of the mountains, while higher up the mountains is a certain amount of summer pasture. In Dzungaria saxaul and tamarisk trees are characteristic. There are fine forests in the Borotala and Ili valleys, and often on the mountain slopes, mostly pine and birch. The northern slopes of the Tien Shan are famed as summer grazing lands. Where irrigation is possible, in certain places near the Tarim, there is some good cultivation of cereals, rice, cotton and fruits. The wild animals include the camel, wild ass, wolf, tiger, yak, gazelle, stag, etc. The nomads keep horses, camels, cattle, sheep, goats and asses.

Sulphur, saltpetre and alum are found at certain places, as in the Turfan depression and near Yarkand. Iron and lead were once mined in the Ili region. Coal occurs in the Turfan depression near Kurla and west of Kashgar, and the latter region also yields lead and copper. The famous Chinese jade occurs south of Khotan and Yarkand, where some of the rivers have golden sands.

The region north of Tien Shan is famed as the home of nomads, who find good summer pasture on the heights. They are mainly Turkoman, including Kirghiz and Kazaks, mainly Sunni Mohammedans; the Mongol element is Buddhist in religion. Turki is the prevalent language. South of Tien Shan is the region of oases, with little opportunity for nomads, save as rulers or marauders, except among the mountains. Here again Turki is spoken and Sunni Mohammedanism is the general religion, but there are Shiah Mohammedans in the south-western mountains. The Chinese element is mainly administrative, and is said to have come largely from the Tientsin area; they are found especially at Urumtsi, the political capital of the dominion on the north side of the Tien Shan. The governor of Sin Kiang is nominally under the viceroy of Kansu; there are four Intendances of Urumtsi, Kuldja, Kashgar and Aksu, and these are divided into 16 prefectures.

The cultivators of the irrigated lands live on cereals, beans and fruit, and grow a good deal of linseed for oil, etc., as well as silk and cotton. Some tea is grown. The towns of the oases of the Tarim basin include Aksu, Kashgar, Yarkand, Khotan. The Ili basin has Kuldja, Dzungaria has Urumchi. The Turfan depression has Turfan. These towns are trading centres with business in skins, silk, cotton, carpets, etc.

The chief roads are (*a*) from Kansu along the north via Hami and Urumchi to Kuldja, (*b*) via Hami to Turfan, Karashar, Aksu, Kashgar and so to Bukhārā, with a branch from Kashgar to Yarkand, and (*c*) a way from Kansu via Lop Nor and Keruja to Khotan and Yarkand; this last is much less important than the others. (*See* also TAKLA-MAKAN; TARIM; ASIA, *Archaeology*.)

SINKING FUNDS, funds specifically ear-marked for the extinction of a debt, especially a national debt. *See* NATIONAL DEBT.

SINOPE (*sinūb*), the capital of a vilayet on the North coast of Asia Minor, on a low isthmus joining the promontory of Boz Tepé to the mainland. Though it possesses the only safe roadstead between the Bosporus and Batum, the difficulties of communication with the interior, and the rivalry of Ineboli on the West and Samsun on the East have prevented Sinope from becoming a great commercial centre. It is shut off from the plateau by forest-clad mountains. Pop. (1927) 32,426. On the isthmus, towards the mainland, stands a huge but for the most part ruined castle, originally Byzantine and afterwards strengthened by the Seljuk sultans; and the Mohammedan quarter is surrounded by massive walls. Of early Roman or Greek antiquities there are only the columns, architraves and inscribed stones built into the old walls; but the ancient local coinage furnishes a very beautiful and interesting series of types.

See M. Six's paper in the *Numismatic Chronicle* (1885), and MM. Babelon & Reinach, *Recueil des monnaies grecques d'Asie Mineure* (1904).

Sinope (Σινώπη), whose origin was assigned by its ancient inhabitants to Autolycus, a companion of Hercules, was founded 630 B.C. by the Ionians of Miletus, and ultimately became the most flourishing Greek settlement on the Euxine, as it was the terminus of a great caravan route from the Euphrates, through Pteria, to the Black Sea, over which were brought the products of Central Asia and Cappadocia (whence came the famous "Sinopic" red earth). In the 5th century B.C. it received a colony of Athenians; and by the 4th it had extended its authority over a considerable tract of country. Its fleet was dominant in the Euxine, except towards the West, where it shared the field with Byzantium. When in 220 B.C. Sinope was attacked by the king of Pontus, the Rhodians enabled it to maintain its independence. But where Mithradates IV. failed Pharnaces succeeded; and the city, taken by surprise in 183 B.C., became the capital of the Pontic monarchy. Under Mithradates VI. the Great, who was born in Sinope, it had just been raised to the highest degree of prosperity, with fine buildings, naval arsenals and well-built harbours, when it was captured by Lucullus and nearly destroyed by fire (70 B.C.). In 64 B.C. the body of the murdered Mithradates was brought home to the royal mausoleum. Under Julius Caesar the city received a Roman colony, but was already declining with the diversion of traffic to Ephesus, the port for Rome, and in part to Amisus (Samsun). In the middle ages it became subject to the Greek Empire of Trebizond, and passed into the hands of the Seljuk Turks, and in 1461 was incorporated in the Ottoman Empire. In November 1853 the

Russian vice-admiral Nakhimov destroyed here a division of the Turkish fleet and reduced a good part of the town to ashes.

SINTER, a word taken from the German (allied to Eng. "cinder") and applied to certain mineral deposits, more or less porous or vesicular in texture. At least two kinds of sinter are recognized—one siliceous, the other calcareous. Siliceous sinter is a deposit of opaline or amorphous silica from hot springs and geysers, occurring as an incrustation around the springs, and sometimes forming conical mounds or terraces. The pink and white sinter-terraces of New Zealand were destroyed by the eruption of Mt. Tarawera in 1886. Mr. W. H. Weed, on studying the deposition of sinter in the Yellowstone national park, found that the colloidal silica was largely due to the action of algae and other forms of vegetation in the thermal waters (*9th Ann. Rep. U.S. Geol. Surv.*, 1889, p. 613). Siliceous sinter is known to mineralogists under such names as geyserite, fiorite and michaelite. (*See* OPAL.)

Calcareous sinter is a deposit of calcium carbonate, exemplified by the travertine, which forms the principal building stone of Rome (Ital. *travertino,* a corruption of *tiburtino,* the stone of Tibur, now Tivoli). The so-called "petrifying springs," not uncommon in limestone-districts, yield calcareous waters which deposit a sintery incrustation on objects exposed to their action. The cavities in calcareous sinter are partly due to the decay of mosses and other vegetable structures which have assisted in its precipitation. Even in thermal waters, like the hot springs of Carlsbad, Bohemia, which deposit *Sprudelstein,* the origin of the deposits is mainly due to organic agencies, as shown as far back as 1862 by Ferd. Cohn. Whilst calcareous deposits in the open air form sinter-like travertine, those in caves constitute stalagmite.

SINUS. Anatomically the term refers to a space filled with blood or air. The word is also used by surgeons to signify a discharging track which will not heal and has in many cases a foreign body, or dead bone at the bottom. Popularly the expression "Sinus trouble" implies an infection, acute or chronic, of one of the air-containing cavities connected with the nose. The largest of these cavities (the antrum) is contained in the cheek-bone; the next in size in the forehead (frontal sinus); smaller cavities open into the back (sphenoidal sinus) and sides (ethmoidal cells) of the nose. (*See* NOSE, ANATOMY OF.)

An *acute* infection of one or more of these sinuses is liable to follow a severe cold, influenza, or other acute infectious illness. There will be pain, often wrongly described as neuralgia, in the face, forehead or behind the eye, which usually comes on about the same time every day. There is sometimes discharge from the nose. The pain is caused by the discharge which collects in the sinus and cannot get out because of swelling of the mucous membrane covering the communication with the nose. Menthol reduces this swelling and thus relieves the pain. A piece of menthol the size of a pea may be placed in a jug of boiling water and the vapour inhaled through the nose. Radiant heat, *e.g.,* a powerful electric light bulb, held close to the forehead or face, is also helpful.

A *chronic* infection of one or more of the sinuses may follow an acute attack or may be associated with chronic nasal obstruction or catarrh. An infection of the antrum may also result from dental disease. Pain may be entirely absent. Sometimes, but by no means always, there is a thick discharge (pus) which may run back into the throat. A discharge from one side of the nose is suggestive of sinus disease. Sometimes the discharge has an unpleasant smell especially when it is derived from an infected antrum. Although causing few symptoms, or indeed none whatever, sinus trouble is important because an infected sinus may act as a "septic focus" and cause disease of the eye, ear, joints, stomach, or indeed of almost any other part of the body, or it may be the starting point of a troublesome neuralgia. Sometimes, especially in the case of the antrum, repeated washing out may result in cure. Usually however, operative treatment is required. This consists in enlargement of the opening into the nose so as to allow free drainage or more rarely complete obliteration of the sinus.

Sinus trouble is prevented by avoidance of colds and early treatment of nasal obstruction and catarrh and of dental disease. It is probable that living in hot stuffy rooms increases susceptibility to sinus infection. (*See* OLFACTORY SYSTEM.)

(S. HA.)

SION, the capital of the Swiss canton of the Valais (1,680 ft. above sea-level). In 1920 it had 6,951 inhabitants (mainly Roman Catholics), of whom 1,344 were German-speaking and 5,379 French-speaking. Sion (*Sedunum*) dates from Roman times, and the bishop's see was removed thither from Martigny (*Octodurum*) about 580. In 999 the bishop received from Rudolf III., king of Burgundy, the dignity of count of the Valais, and henceforward was the temporal as well as the spiritual lord of the Valais, retaining this position, at least in part, till 1798. Sion is one of the most picturesque little cities in Switzerland, being built around two prominent hillocks. The north hillock is crowned by the castle of Tourbillon (built 1294, burnt 1788), which was long the residence of the bishops. The south hillock bears the castle of Valeria (which now contains an historical museum) with the interesting 13th century church of St. Catherine.

See also J. Gremaud, Introduction to vol. v. (Lausanne, 1884) of his *Documents relatifs à l'histoire du Vallais,* and R. R. Hoppeler, *Beiträge zur Geschichte des Wallis im Mittelalter* (Zürich, 1897).

SION COLLEGE, in London, an institution founded as a college, gild of parochial clergy and almshouse, under the will (1623) of Dr. Thomas White, vicar of St. Dunstan's in the West. The clergy who benefit by the foundation are the incumbents of the City parishes, of parishes which adjoined the city bounds when the college was founded, and of parishes subsequently formed out of these. In 1886 Sion College was moved from its original buildings in London Wall to the Victoria Embankment, and is now principally known for its theological library which serves as a lending library to members of the college, and is accessible to the public. A governing body appointed by the members to administer the foundation consists of a president, two deans and four assistants.

SIOUAN INDIANS. This great family of American natives takes its name from that of the largest tribe, the Sioux or Dakota (*q.v.*). Next to the Algonkin, they were perhaps the most populous stock north of Mexico. They held three territories, the largest mainly west of the Mississippi river, another, east of the Appalachian mountains in Virginia and the Carolinas; the smallest, in two fragments, in Mississippi. The last two divisions are nearly extinct. The culture was not uniform, but accorded with the region in which each tribe lived. Physical types probably varied similarly. In the Plains area, the Siouans were the preponderant linguistic stock. The principal tribes were (those asterisked being separately treated): 1, in the west, *Dakota and *Assiniboin, the former really seven tribes; *Mandan, *Hidatsa and *Crow; *Winnebago; tribes speaking the Chiwere dialect, namely the Iowa, Oto Missouri; tribes speaking Dhegiha, viz., *Omaha, Ponca, Kansa, *Osage, Quapaw or Arkansas; 2, in the south, Ofo and Biloxi; 3, in the east, Monacan, Manahoac, Tutelo, Saponi, Occaneechi, Woccon, *Catawba, Santee, Cheraw or Sara, and probably Wateree, Congaree, Pedee and others. About 40,000 remain; the original numbers were probably at least twice as great.

(A. L. K.)

SIOUX CITY, a city of western Iowa, U.S.A., on the Missouri river at the mouth of the Big Sioux, 500 m. W. of Chicago; a port of entry, the county seat of Woodbury county, and the second city of the State in size. It is on Federal highways 20, 75 and 77; has municipal and commercial airports; and is served by the Burlington Route, the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, the Chicago, St. Paul, Minneapolis and Omaha, the Great Northern and the Illinois Central railways. Pop. (1920) 71,227 (15·7% foreign-born white, the majority from Russia, Sweden, Norway and Germany); 79,183 in 1930 by the Federal census. The city has a beautiful site of 45 sq.m., at an altitude of 1,158 ft. The narrow lowlands along the rivers and creeks are occupied by industry and commerce, while the several distinct residential districts are built on high bluffs, commanding views into three States. On opposite sides of the city stand reminders of the coming of the white man and

the departure of the Indian: a shaft of white stone erected to the memory of Sergeant Charles Floyd of the Lewis and Clark expedition, who died here in 1804; and the grave of War Eagle (d. 1851), a powerful chief of the Yankton Sioux and a friend of the early settlers. In Riverside park is the Council Oak, under which took place many councils of war and peace. The park system includes 1,119 acres. There are 82 churches and 31 public schools. The hotels have 2,000 guest rooms and the hospitals 800 beds. Since 1912 the city was operated under a commission form of government. It is the see of a Roman Catholic bishop, and is the seat of several institutions of that church and of Morningside college (Methodist Episcopal, 1894). Sioux City is an important jobbing, marketing and manufacturing centre. The output of its factories in 1927 was valued at $124,585,809.

The site of Sioux City was a favourite camping ground and meeting place of the Indians. The first white visitors of record were Lewis and Clark and their companions in 1804. In 1848 William Thompson built a cabin on the bluff where Sergeant Floyd had been buried; and in 1849 Théophile Brughier, a French Canadian in the employ of the American Fur Company, settled at the mouth of the Big Sioux river, was received into the tribe of the Yankton Sioux, and married War Eagle's daughter. In 1854 the city was platted by Dr. John K. Cook, who was surveying a part of the region for the U.S. Government. The first mail arrived in July, 1855; the first steamboat from Saint Louis in June, 1856. The city was incorporated in 1857, with a population of 400. In 1868 the first railroad reached the city, and a few years later a packing plant was established. The decade 1880–90 was a period of phenomenal development. The population increased from 7,366 to 37,806; factories, commercial houses and railroads multiplied; public improvements and utilities were begun on a large scale. The panic of 1893 brought temporary depression and an actual loss of population between 1890 and 1900; but since 1900 growth and progress have again been rapid, the population increasing 115% in the first 20 years of the century.

SIOUX FALLS, the largest city of South Dakota, U.S.A., on the Big Sioux river, at an altitude of 1,422 ft., 190 m. N. by W. of Omaha; the county seat of Minnehaha county. It is on the Atlantic–Yellowstone–Pacific and the Custer Battlefield highways; has a municipal airport 3 m. S.E. of the post-office; and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Chicago, St. Paul, Minneapolis and Omaha, the Great Northern, the Illinois Central, and the Rock Island railways, and by 20 interurban motor-coach lines. Pop. (1925 State census) 30,127; 1930 Federal census 33,362. Sioux Falls is the metropolis of a large territory. The falls from which it takes its name are a series of cascades, dropping about 100 ft. in half a mile, which provide picturesque scenery as well as water-power. There are 324 ac. in public parks. The residential sections have wide tree-lined streets, bordered with lawns and gardens. Many of the public buildings and institutions are built of "Sioux Falls granite" (quartzite sandstone) quarried in the vicinity. The city is the see of a Roman Catholic and of a Protestant Episcopal bishop, and is the seat of the State penitentiary, the State school for the deaf, the South Dakota Children's Home (a privately supported institution), Sioux Falls college (Baptist; 1883), Augustana College and Normal School (Lutheran; 1889), Columbus college (Roman Catholic; 1921) and three training schools for nurses. It is an important distributing centre. The output in 1927 of 77 factories in the city was valued at $38,363,882. A settlement was established at the falls in 1856, but it was abandoned six years later. Permanent settlement dates from 1867. The village was incorporated in 1877, and in 1883 it was chartered as a city. By 1900 the population had reached 10,266. This increased to 14,094 in 1910, and then more than doubled in the next 15 years.

SIPHANTO: *see* SIPHNOS.

SIPHNOS (It. and mod. Gr. *Siphanto, Siphěno*), an island of the Greek Archipelago, 30 m. S.W. of Syra (area 28 sq.m.). Along the west slope of a limestone ridge, whose principal summits, Hagios Elias and Hagios Simeon, are crowned by old Byzantine churches, lies a series of villages, each white-washed house with its own garden and orchard. Apollonia, the modern capital has the name of an ancient town: Kastro has mediaeval fortifications, and the town hall bears the date 1365. Inscriptions show that Kastro represents the ancient city of Siphnos. Another ancient town, Minoa, is marked by two Hellenic white marble towers known as the Pharos (lighthouse) and St. John. Byzantine churches and convents are scattered about the island. The "School of the Holy Tomb" was founded by Greek refugees from the iconoclastic persecutions at Byzantium and became a centre of culture. Its endowments are now held by the gymnasium of Syra.

In ancient times Siphnos was colonized by Ionians from Athens. It refused tribute to Xerxes, and sent one ship to fight on the Greek side at Salamis. It was famous for its gold and silver mines, easily recognized by excavations and refuse-heaps. In antiquity, as now, it exported pottery. During the Venetian period it was ruled first by the Da Corogna family and after 1456 by the Gazzadini, who were expelled by the Turks in 1617.

SIPHON or SYPHON, an instrument, usually in the form of a bent tube, for conveying liquid over the edge of a vessel and delivering it at a lower level (Lat. *sipho;* Gr. *σίφων,* a tube). The action depends upon the difference of the pressure on the liquid at the extremities of the tube, the flow being towards the lower level and ceasing when the levels coincide. The instrument affords a ready method of transferring liquids, and is made of glass, indiarubber, copper or lead, according to the liquid which is to be transferred. The simple siphon is used by filling it with the liquid to be decanted, closing the longer limb with the finger and plunging the shorter into the liquid; and it must be filled for each time of using. Innumerable forms have been devised adapted for all purposes, and provided with arrangements for filling the tube, or for keeping it full and starting it into action automatically when required. Pipes conveying the water of an aqueduct across a valley and following the contour of the sides are sometimes called siphons, though they do not depend on the principle of the above instrument. In the siphon used as a container for aerated waters a tube passes through the neck of the vessel, one end terminating in a curved spout while the other reaches to the bottom of the interior. On this tube is a spring valve which is opened by pressing a lever. The vessel is filled through the spout, and the water is driven out by the pressure of the gas it contains, when the valve is opened. The "Regency portable fountain," patented in 1825 by Charles Plinth, was the prototype of the modern siphon, from which it differed in having a stopcock in place of a spring valve. The "siphon champenois" of Deleuze and Dutillet (1829) was a hollow corkscrew, with valve, which was passed through the cork into a bottle of effervescent liquid, and the "vase siphoïde" of Antoine Perpigna (Savaresse *père*), patented in 1837, was essentially the modern siphon, its head being fitted with a valve which was closed by a spring.

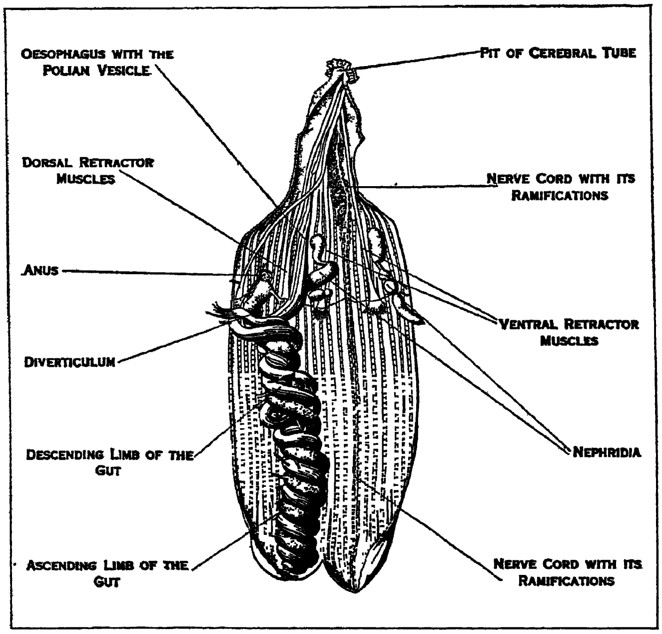
SIPHONAPTERA, an order of insects (*q.v.*) comprising the fleas (*q.v.*).

SIPPAR, a city of ancient Mesopotamia, situated in 33° N., 44° E. The site to-day lies five miles east of the Euphrates, just south of the Royal canal (Nahr al Malik), but in ancient times the Euphrates flowed by the city. The temple of E-Babbar, "the House of the Sun" and its stage tower (*ziggurat*) occupied a terrace beside the river with a superficial area of about 1,300 square feet. East of the temple area and separated from it by a wide avenue lay the residential quarter, the whole city being surrounded by a wall. This wall forms a rectangle, 860 yards wide and 1,400 yards long, the long sides facing north and south. The excavations in the northern part of the eastern mound and on the ziggurat produced over 60,000 tablets, chiefly contracts, and religious and grammatical texts of Neo-Babylonian date. The antiquity of the city however is shown by the fact that there are ancient records of the Euphrates being called the river of Sippar. Its Sumerian name appears to have been Zib-Bar Nun. The Sumerian Sun god was identified with the Semitic Shamash, and it was in this city that the Sun god had his principal cult. In ancient times the two rivers approached closely here and the site therefore commanded the entrance to the southern plain from the north.

See *Cambridge Ancient History,* vol. i., 1923 (bibliography).

SIPUNCULOIDEA, marine animals of uncertain affinities formerly regarded as a subdivision of the class Gephyrea (*q.v.*). Some authorities have linked them with the Phoronidea (*q.v.*) as the Podaxonia, but they are here treated as autonomous. A number of fossil forms occur in the Middle Cambrian of British Columbia.

General Description.—The body is fusiform with a glistening cuticle, and may attain a length of about 12 inches. The body-wall comprises a thick cuticle, an epidermis containing glandular bodies, a thin sheet of connective tissue, several layers of muscle, and finally a coelomic epithelium. The anterior part, the proboscis or introvert, is capable of being retracted into the remainder as the tip of a glove-finger may be pushed into the rest: at the top of the introvert is the mouth, surrounded in *Sipunculus* by a laciniated funnel, but more usually by tentacles each with its ciliated groove creating a current in the direction of the mouth. The mouth leads into the oesophagus surrounded by the retractor muscles of the introvert, which arise in the body-wall about one-third of the body-length from the anterior end. The alimentary canal is a thin-walled tube, not marked off into definite regions, which runs to the posterior end of the body and then turns forward to end in the dorsal anus near the insertion of the retractor muscles. The descending and ascending limbs of the gut are twisted into a spiral coil, the axis of which is often traversed by a muscle arising from the posterior end of the body. Along most of the gut runs a ciliated groove, into which food does not enter. A diverticulum of variable size opens into the rectum. On the dorsal surface of the oesophagus lies a contractile body, the Polian vesicle, filled with corpusculated fluid and closed posteriorly; it opens in front into a circumoesophageal ring, giving off branches to the tentacles, which by its contraction are caused to expand. The excretory organs consist usually of two saccular brown tubes attached by one side to the ventral wall of



FROM THEEL, "NORTHERN AND ARCTIC INVERTEBRATES" (VETENSKAPSAKADEMIEN)

GENERAL DISSECTION OF SIPUNCULUS PRIAPULVIDES FROM THE DORSAL SURFACE SHOWING THE INTERNAL ORGANS IN POSITION

the body and opening to the exterior by a pore. The ventral lip of the internal ciliated funnel is a portion of the coelomic epithelium; the funnel leads by a canal into the nephridial sac. These organs serve both for excretion and for the passage of the genital products: the former function is also served by certain cellular bodies, the urns, which may be free in the coelom or attached to the outer wall of the gut. The essential part of these organs is a ciliary mechanism by which the waste products in the coelomic fluid are agglutinated and brought into contact with the phagocytes, and so eliminated. J. Cantacuzène has shown that the urns are important in the production of immunity. The Sipunculoids are dioecious, and the germ cells arise from the coelomic epithelium near the insertion of the retractor muscles; they drop into the coelom at an early stage and there develop. The coelom is rich in corpuscles and contains haematids carrying a respiratory pigment, haemerythrin, rich in iron. There is a well-developed dorsal brain, usually with two pigmented eye-spots at the bottom of an epidermal invagination passing deeply into it; in some genera this cerebral tube is divided into two: the brain is also connected with the heart-shaped nuchal organ, to the lateral ciliated lobes of which it gives off two large nerves. A nerve-ring joins the brain to the ventral nerve-cord, in which there are no distinct ganglia but a series of ganglion cells. The nerve-cord gives off numerous nerves to the periphery.

Classification.—The Sipunculoids are divided into a number of genera separated on the arrangement and number of the longitudinal muscles and tentacles, the presence of calcareous bodies on the posterior end, etc.

Development.—Segmentation is spiral. The larva is a trochophore but with no protonephridia and flame-cells. The development is characterized by the enormous elongation of the post-anal region which brings about the dorsal and anterior situation of the anus.

Ecology.—Some Sipunculoids live in mud and sand and feed on the organic matter contained in them (*Sipunculus*); others (*Phascolosoma, Physcosoma*) occupy crevices and rock-crannies; others again (*Phascolion, Aspidosiphon*) inhabit the shells and tubes formed by other small marine animals. The two latter groups feed on detritus, etc., which are conveyed to their mouths by means of the cilia on their tentacles. Only the mud and sand dwellers are capable of free movement.

BIBLIOGRAPHY.—The best account of the group as a whole is that by J. W. Spengel, 1913, in the *Handwörterbuch der Naturwissenschaften,* Jena, vol. ix., pp. 97–106, 14 figs. with a bibliography.
See also L. Cuénot, 1922, "Sipunculiens," *Faune de France,* iv., pp. 1–17, figs. and bibl. (C. C. A. M.)

SIQUIJOR, a municipality (with administration centre and 42 *barrios* or districts) of the sub-province of Siquijor, attached to the province of Oriental Negros, island of Negros, Philippine Islands. It is situated on the small coral island of Siquijor, about 14 m. S.E. of Dumaguete, the capital of the province. Pop. (1918), 15,237. The principal industry is the cultivation of coco-nuts and the manufacture of copra. Tobacco, rice, corn, abacá are other agricultural products. In 1918 it had 139 household industry establishments with output valued at 23,700 pesos. Of the 11 schools, 10 were public. The language is a dialect of Bisayan.

SIRDAR or **SARDAR,** a title applied to native nobles in India, *e.g.,* the sirdars of the Deccan (Persian *sardar,* meaning a leader or officer). Sirdar Bahadur is an Indian military distinction; and Sirdar is now the official title of the commander-in-chief of the Egyptian army.

SIRENIA, an order of aquatic placental mammals, comprising the manatees or sea-cows, the dugongs, the recently extinct Steller's sea-cow (*Rhytina*), as well as their fossil relatives of the Tertiary period. The torpedo-shaped body ends behind in a horizontal tail fluke, as in the dolphins; but in contrast with the latter the broad muzzle is truncate and the transversely expanded lips are very mobile. The name Sirenia was given in allusion to the supposed resemblance of these animals to mermaids. A dugong as seen at a distance from the deck of a ship and especially if floating half upright, with its baby under its flipper, might well be mistaken for a mermaid; and many legends gathered round them in the early days of exploration of the Indian ocean. For the evolutionary history and relationships of the Sirenia, *see* UNGULATA.

SIRENS, in Greek mythology, the daughters of Phorcys the sea-god (Gr. Σειρῆνες), or, in later legend, of the river-god Acheloüs and one of the nymphs. In Homer they are two in number (in later writers generally three); their home is an island in the western sea between Aeaea, the island of Circe, and the rock of Scylla. They are nymphs of the sea, who lured mariners to destruction by their sweet song. Odysseus, warned by Circe,

escaped the danger by stopping the ears of his crew with wax and binding himself to the mast until he was out of hearing (*Odyssey* xii.). When the Argonauts were passing by them, Orpheus sang so beautifully that no one had ears for the Sirens. After one or other of these failures they drowned themselves. When the adventures of Odysseus were localized on the Italian and Sicilian coasts, the Sirens were transferred to the neighbourhood of Neapolis (Naples) and Surrentum, the promontory of Pelorum at the entrance to the Straits of Messina, or elsewhere. The tomb of one of them, Parthenope, was shown in Strabo's (v. p. 246) time at Neapolis, where a gymnastic contest with a torch-race was held in her honour.

Perhaps the most reasonable explanation of the Sirens is that they are soul-birds; *i.e.*, winged ghostly figures who fetch the living to join them. They are in this respect not unlike the Harpies (*q.v.*); so Weicker. In early art, they were represented as birds with the heads of women; later, as female figures with the legs of birds, with or without wings.

See H. Schrader, *Die Sirenen* (1868); Preller-Robert, *Griechische Mythologie* (1894), pp. 614–616; G. Weicker, *Der Seelenvogel in der alten Literatur und Kunst* (1902) (Bibl.), and in Roscher's *Lexikon*, art. *Seirenen*.

SIRGUJA or **SURGUJA,** one of the Chota Nagpur feudatory states transferred in 1905 from Bengal to the Central Provinces. It is bounded on the north by the State of Rewa and on the north and north-east by the districts of Mirzapur and Ranchi; on the south is Bilespur; it thus borders three provinces. In the central portion, there is fairly well cultivated country, surrounded on three sides by massive hill barriers and tablelands, of which the *Jamirapat,* a winding ridge 2 miles in width, separates it from Chota Nagpur. The southern barrier of the State is the *Mainpat,* a fine tableland 18 m. by 6 m. with an elevation rising to 3,700 feet. The Ramgarh hill is a rectangular mass of sandstone rising abruptly from the plain, containing a remarkable natural tunnel, many rock caves and remains of temples made of enormous blocks of stone. There are other ruins in the jungles, indicating a higher state of civilization at an earlier epoch than that now prevailing. The area of the State is 6,055 sq.m., and the population (1921) was 377,679. This comprises some 200,000 Hindus and 4,000 Mohammedans and the rest of the population is made up of a remarkable variety of different aboriginal tribes, some of which must have been very ancient. The chief, on whom the title of maharaja has been conferred, comes of ancient Rajput lineage.

SIRHIND, a tract of land in the Punjab, India. It consists of the north-eastern portion of the plain between the Jumna and Sutlej rivers, and is watered by the Sirhind canal, which draws its water-supply from the Sutlej near Rupar. The canal, which was opened in 1882, irrigates over 2,000 sq.m.

SIRICIUS, pope from Dec. 384 to Nov. 399, successor of Damascus. The disfavour which he showed to the monks led to the departure of Jerome from Rome to Bethlehem. Several of the decretal letters of Siricius are extant, setting forth the rules of ecclesiastical discipline. Under his pontificate a general council was convened at Capua in 391, which discussed various Eastern affairs. The council of Capua, inspired by the pope, deferred to the council of Macedonia the affair of Bonosus, bishop of Sardinia, who had been accused of heresy. To safeguard the authority of the Holy See over the bishops of Illyricum, Siricius entrusted his powers to the bishop of Thessalonica, who was henceforth the vicar of the pope in those provinces. Siricius maintained his protest, made in 386, against the attitude of Bishop Ithacius, the accuser of Priscillian, although he disapproved of the latter's doctrines. During his pontificate the last attempt to revive paganism in Rome was made (392–394) by Nicomachus Flavianus. Siricius died on Nov. 26, 399.

SIRIUS, the "dog star," is the brightest star in the heavens. It is situated in the constellation Canis Major (*q.v.*). The mythology and early references to it are discussed in the article CANIS MAJOR. In 1844 Bessel found that Sirius was not moving uniformly through the heavens, being sometimes ahead and sometimes behind the mean position. He deduced that (in addition to uniform proper motion) it had a motion in an elliptic orbit in a period of about 50 years. This indicated that an unseen star must be present, forming with Sirius a double star. In 1862 Alvan Clark, who was testing a large new object-glass, unexpectedly detected the companion as a faint point of light amid the glare of Sirius itself.

Sirius is one of the nearest stars and its parallax has been measured with considerable accuracy. Its distance is 2·7 parsecs =8·8 light years=51 million million miles. Its apparent brilliance is due more to its nearness than to actual luminosity; absolutely it is about 28 times as bright as the sun—a luminosity which is not at all exceptional. Its mass has been determined by Kepler's laws from the double star orbit and is 2·4 times that of the sun. Its spectrum shows that the surface temperature is much higher than the sun's (about 10,000° against 6,000°) and its light is correspondingly whiter. It is a typical star of the spectral class A0, in which the Balmer series of hydrogen is most strongly developed.

The companion is a remarkably interesting body. It revolves at a distance from Sirius nearly equal to the distance of Uranus from the sun in a period 49 years. Although it has one-third the mass of Sirius it gives less than $\frac{1}{10,000}$ of the light. A more convenient comparison is with the sun; it has 0·85 of the sun's mass, but only $\frac{1}{360}$ of the sun's light. It seemed natural to assume that it must be radiating feebly like a star on the verge of extinction, but in 1914 W. S. Adams made the surprising discovery that its spectrum was not much different from that of Sirius itself. This indicates a white light coming from a surface at high temperature and radiating more intensely than the sun's surface. If the small total light is not due to low emitting power, it must be due to small dimensions. Reasoning in this way the radius is found to be 18,800 km.; *i.e.*, intermediate between the earth and the next larger planet Uranus. The mass, which is 0·85 of the sun's or 250,000 times that of the earth, has to be squeezed into this small sphere; and the resulting density is 61,000 times that of water or about a ton to the cubic inch.

The result at first seemed incredible, but the cause of the supposed breakdown of this natural inference remained a mystery. In 1924, however, it was discovered that, owing to the breaking up of the outer systems of electrons in the atoms under the high temperature prevailing in the interior of a star, stellar matter would not offer the resistance to high compression that terrestrial matter does. It was therefore quite conceivable that densities might be attained in the stars far transcending the greatest known terrestrial densities. It was suspected that this might be the explanation of the result for the companion of Sirius. Accordingly, in 1924–25 W. S. Adams carried out a special test, depending on the Einstein effect in the star's spectrum, in order to check the high density. This effect is a lengthening of the wave-length of light which has come from a place of high gravitational potential, manifesting itself as a displacement of the spectral lines towards the red. It is thus theoretically possible to calculate the potential at the surface of a star (*i.e.*, the mass divided by the radius) if the magnitude of the Einstein effect can be measured. In all ordinary stars the shift is too small to measure; it is believed to have been found in the sun, but this can scarcely yet be regarded as certain. But if the foregoing dimensions of the companion of Sirius are right, the Einstein shift will be 30 times as great as on the sun. This quantity should be very easily measurable, were it not for special difficulties which arise from the faintness of the star and the interference of the scattered light from Sirius. Adams applied the test and his results are believed to be trustworthy; they definitely confirm the large spectral shift predicted. It appears therefore that the companion of Sirius is a genuine example of matter compressed to enormously high density—more than 2,000 times the density of platinum.

BIBLIOGRAPHY.—For the high density of the companion of Sirius: A. S. Eddington, *Monthly Notices of Roy. Ast. Soc.*, 84, p. 322 (1924); W. S. Adams, *Proc. Nat. Acad. Sci. Washington*, II., p. 382 (1925). The remarkable physical conditions arising from the high density are discussed by R. H. Fowler, *Monthly Notices*, 87, p. 114 (1926).

(A. S. E.)

SIRMUR or **SARMOR,** an Indian State, within the Punjab. It is also called Nahan, after the chief town. It occupies the

lower ranges of the Himalaya, between Simla and Mussoorie. Area 1,198sq.m. On the northern frontier Chor Peak and station are about 12,000ft. above the sea. Pop. (1921), 140,448. Estimated gross revenue, £45,000.

SIROCCO, a term used specifically for the hot, dry wind in Sicily and south Italy, but the name is in general use on the north Mediterranean seaboard for any warm southerly wind; such winds may be either moist or very dry, and represent the air current in front of the depressions advancing eastward over the Mediterranean sea. (*See* LEVECHE; LESTE; KHAMSIN; SIMOOM; and *Meteorological Office Publication No. 224,* 1919.)

SIROHI, an Indian state in the Rajputana agency. Area 1,958 sq.m. The country is much broken up by hills and rocky ranges; the Aravalli range traverses it from north-east to south-west. The south and south-east part of the territory is mountainous and rugged, containing the lofty Mount Abu. The only river of any importance is the Western Banas. A large portion of the state is covered with dense jungle, in which wild animals, including the tiger, bear and leopard, abound. Many splendid ruins bear witness to the former prosperity and civilization of the country. On Abu the average annual rainfall is about 64 in., whereas in Erinpura, less than 50 m. to the north, the average fall is only between 12 and 13 in. Pop. (1921) 186,639.

In 1823 a treaty was concluded with the British government. For services rendered in 1857 the chief received a remission of half his tribute. The chief, whose title is maharao, is a Deora Rajput of the Chauhan clan, and enjoys a salute of 15 guns.

The town of SIROHI is 28 m. N. of Abu-road station. Pop. (1921) 6,197. It has manufactures of sword-blades and other weapons.

SIS or Kozan (anc. *Sision* or *Siskia,* later *Flaviopolis* or *Flavias*), a kaza in the Adana vilayet of Asiatic Turkey, situated on the left bank of the Kirkgen Su, a tributary of the Jihun (Pyramus) and at the south end of a group of passes leading from the Anti-Taurus valleys to the Cilician plain and Adana. It was besieged by the Arabs in 704 but relieved by the Byzantines. The Caliph, Motawakkil took it and refortified it; but it soon returned to Byzantine hands. It was rebuilt in 1186 by Leo II., king of Lesser Armenia, who made it his capital. In 1374 it was taken and demolished by the sultan of Egypt, and it has never recovered its prosperity. It is now only a big village of some 3,000 inhabitants. It has had, however, a great place in Armenian ecclesiastical history from the times of St. Gregory the Illuminator to our own. Gregory himself was there consecrated the first Catholicus in A.D. 267, but transferred his see to Vagarshabad (Echmiadzin, Etchmiadzin), whence, after the fall of the Arsacids, it passed to Tovin. After the constitution of the kingdom of Lesser Armenia, the catholicate returned to Sis (1294), the capital, and remained there 150 years. In 1441, Sis having fallen from its high estate, the Armenian clergy proposed to remove the see, and on the refusal of the actual Catholicus, Gregory IX., installed a rival at Echmiadzin, who, as soon as Selim I. had conquered Greater Armenia, became the more widely accepted of the two by the Armenian church in the Ottoman empire. The Catholicus of Sis maintained himself nevertheless, and was supported in his pretensions by the Porte up to the middle of the 19th century, when the patriarch Nerses, declaring finally for Echmiadzin, carried the government with him. In 1885 Sis tried to declare Echmiadzin schismatic, and in 1895 its clergy took it on themselves to elect a Catholicus without reference to the patriarch; but the Porte annulled the election, and only allowed it six years later, on Sis renouncing its pretensions to independence. The lofty castle and the monastery and church built by Leo II., and containing the coronation chair of the kings of Lesser Armenia, are interesting. (D. G. H.)

SISAK, a town of Croatia-Slavonia, Yugoslavia. Pop. (1921), 8,802. Sisak was a flourishing city under Roman rule. Augustus made it a military station; Tiberius chose it as his headquarters against the Pannonian rebels, and Septimius Severus made it the centre of a military government. In the third century the city contained the chief imperial mint and treasury; and an engraved coffer, found in Croatia, dating from the 4th century, represents *Siscia* among the five foremost cities of the Empire. Its bishopric was removed to Salona in 441, when Attila appeared, and thenceforward the city declined. For a brief period in the 7th and 8th centuries, it was held by the Serbian princes, but in the 10th century it was sacked by the Magyars, and in 1092 its territories were bestowed upon the cathedral chapter of Zagreb (*Agram*) by Ladislaus I., king of Hungary. Under the walls of its castle, built by this chapter in 1544, the Turks were thrice defeated in 1593. At a fourth venture the city fell, only to be evacuated in 1594. It witnessed a final Turkish defeat in 1641, and from that date until 1918 it was included in the Austro-Hungarian empire.

See C. de St. Aymour, *Les Pays sud-slaves de-l' Autriche-Hongroie* (1883).

SISAL HEMP or HENEQUEN, of Florida and the Bahamas, the product of *Agave rigida,* variety *sisalana,* a native of Yucatan, but found in other parts of Central America and distributed to the West Indies, where it is being increasingly cultivated.

Agave (*q.v.*) is a member of the family Amaryllidaceae; and a well-known species of the genus, *Agave americana,* the century plant, will suggest the habit of the sisal hemp, which, however, differs in the absence of prickles along the margin of the fleshy leaf. After six or seven years the flowering stalk or "pole" develops from the centre of the leaf-cluster, and grows to the height of 15 or 20 ft. The flowers are borne in dense clusters at the ends of short lateral branches, and closely resemble those of *Agave americana.* After they have begun to wither, buds are developed from the point of union with the flower-stalk; these form tiny plants, which, when several inches long, become detached and fall to the ground. Those that fall in a suitable place take root and are soon large enough to transplant. After flowering the main plant perishes, but is renewed by suckers springing from the base of the stem; these suckers are then planted, and the leaves should be ready for cutting in about four years. The other method of planting is by means of "pole" plants just described.

In collecting the fibre the leaves are cut off at the base, the spine at the top end removed, and the leaves carried in bundles to the machines. Here two scraping wheels remove the softer parts from the fibre of the leaves. The fibre is yellowish-white, straight, smooth and clean, and a valuable cordage fibre second only to manila fibre in strength.

The plants thrive on arid rocky land, growing, for instance, on the Florida Keys upon the almost naked coral rock. Their northern limit of cultivation is determined by frost; in Florida this is represented by the line of 27° N. An inferior fibre is obtained

ONE END OF A FIBRE CLEANING MACHINE ON A YUCATAN PLANTATION
The tough henequen leaves enter the machine at this end and emerge as clean, white fibre at the other end

from the leaves of another species, *Agave decipiens,* which is found wild along the coasts and keys of Florida. It is known as the false sisal hemp.

SISKIN or **ABERDEVINE** (*Carduelis spinus*), which has long been known in England as a cage-bird, is one of the finches (*q.v.*). It often feeds upon the catkins of alder or birch, frequently hanging upside down like a titmouse. Above, the male is olive-green marked with black and yellow, and beneath, yellowish-white marked with black. His song is not unmelodious. The hen is more soberly attired. The siskin breeds locally throughout

Scotland and parts of England, but more rarely in Ireland. The greater portion, however, of the bands, which visit the British Isles in winter come from the Continent. Its range stretches across Asia to Japan. The nest of the siskin is like that of the goldfinch, but not so neatly built; the eggs, except in their smaller size, resemble those of the greenfinch.

A larger and more brightly coloured species, *C. spinoides*, inhabits the Himalayas. In the United States of America the name siskin or pine siskin is sometimes used for the pine-finch (*Spinus pinus*).

SISLEY, ALFRED (1840–1899), French landscape painter, was born in Paris in 1839, of English parents. He studied painting under Gleyre, and was afterwards influenced, first by Corot, and then by the impressionists Monet and Renoir. He worked both in France and in England, and made the Seine, the Loing and the Thames the subjects of many pictures that are remarkable for the subtle appreciation of the most delicate colour effects. His life was one of constant poverty and hard struggle. He was essentially a colourist who, like Monet, delighted in recording the changing effects of light in the successive hours of the day, and paid little attention to form.

SISMONDI, JEAN CHARLES LÉONARD DE (1773–1842), whose real name was Simonde, was born at Geneva, on May 9, 1773. During the revolutionary disturbances of 1793–94 the Simonde family took refuge in England. On their return the greater part of the family property was sold, and with the proceeds they emigrated to Italy, bought a small farm at Pescia near Lucca, and set to work to cultivate it themselves. Sismondi's experiences gave him the material of his first book, *Tableau de l'agriculture toscane,* which, after returning to Geneva, he published in 1801. In 1803 he published his *Traité de la richesse commerciale.* As an economist, Sismondi represented a humanitarian protest against the dominant orthodoxy of his time. In his first book he followed Adam Smith, but in his principal subsequent economic work, *Nouveaux Principes d'économie politique* (1819), he insisted on the fact that economic science studied the means of increasing wealth too much, and the use of wealth for producing happiness too little.

Meanwhile he began to compile his great *Histoire des Républiques Italiennes du moyen âge,* and became intimate with Madame de Staël. He was invited or commanded (for Madame de Stael's invitations had something of command) to accompany her on the journey into Italy, described in *Corinne.* During this journey he made the acquaintance of the countess of Albany (*q.v.*) Louisa of Stolberg, widow of Charles Edward. Sismondi's relations with her were close and lasted long, and they produced much valuable and interesting correspondence. In 1807 appeared the first volumes of his history. The completion of this book, which extended to sixteen volumes, occupied him for the next eleven years. He lived at first at Geneva, where he held a minor official post. In 1813 he visited Paris for the first time. During the Hundred Days he defended Napoleon's constitutional schemes or promises, and had an interview with the emperor. After the Restoration he left Paris. On completing (1817) his great book on the Italian republics, he undertook (1818) a still greater, the *Histoire des Français,* of which during the remaining twenty-three years of his life he published twenty-nine volumes. Sismondi died at Geneva on June 25, 1842.

Among his other works are: *Littérature du midi de l'Europe* (1813), an historical novel entitled *Julia Severa ou l'an 492* (1822), *Histoire de la Renaissance de la liberté en Italie* (1832), *Histoire de la chute de l'empire romain* (1835), *Précis de l'histoire des Français,* an abridgment of his own book (1839), with several others, chiefly political pamphlets.

Sismondi's journals and his correspondence with Channing, with the countess of Albany and others have been published chiefly by Mlle. Mongolfier (Paris, 1843) and M. de Saint-René Taillandier (Paris, 1863). The latter work serves as the chief text of two admirable *Lundis* of Sainte-Beuve (September 1863), republished in the *Nouveaux Lundis,* vol. vi.

SISSALA. A people resembling the Nunuma who inhabit the borders of Upper Volta (Gourounsi) and the Northern Territories, Gold Coast in Africa, and speak a language related to Nunuma and Kassena. A sub-tribe known as the Puguli live about 70m. west of Leo and Tumu in the Diébougou district of Upper Volta.

See Tauxier, *Le Noir du Soudan* (1912).

SISTERHOODS (Modern Anglican). The dissolution of religious houses in England (1536–1540) under Henry VIII. swept away more than 140 nunneries, and the Anglican Church was left without sisterhoods for three centuries. But as these had for 900 years formed part of her system, there were protests from time to time and attempts at restoration. Amongst such protests, which generally dwelt a good deal on the want of provision for unmarried women, may be mentioned three in successive centuries. The historian Fuller would have been glad "if such feminine foundations had still continued," only without vows (Bk. vi.). Richardson the novelist, in *Sir Charles Grandison,* wishes there could be a Protestant nunnery in every county, "with a truly worthy divine, at the appointment of the bishop of the diocese, to direct and animate the devotion of such a society"; in 1829 the poet Southey, in his *Colloquies* (cxiii.), trusts that "thirty years hence this reproach also may be effaced, and England may have its Béguines and its sisters of mercy. It is grievously in need of them." Also small practical efforts were made in the religious households of Nicholas Ferrar at Little Gidding, 1625, and of William Law at King's Cliffe, 1743; and under Charles II., says Fr. Bede "about 12 Protestant ladies of gentle birth and considerable means" founded a shortlived convent, with Sancroft, then Dean of St. Paul's, for director.

Southey's appeal had weight, and before the thirty years had passed compassion for the needs of the destitute in great cities, and the impulse of a strong Church revival, aroused a body of laymen, among whom were included Mr. Gladstone, Sir T. D. Acland, Mr. A. J. Beresford-Hope, Lord Lyttelton and Lord John Manners (chairman), to exertions which restored sisterhoods to the Church of England. On March 26th, 1845, the Park Village Community was set on foot in Regent's Park, London, to minister to the poor population of St. Pancras. The "Rule" was compiled by Dr. Pusey, who also gave spiritual supervision. In the Crimean War the superior and other sisters went out as nurses with Florence Nightingale. The community afterwards united with the Devonport Sisters, founded by Miss Sellon in 1849, and together they form what is known as Ascot Priory. The St. Thomas's sisterhood at Oxford commenced in 1847; and the mother-superior of the Holy Trinity Convent at Oxford, Marian Hughes, dedicated herself before witnesses to such a life as early as 1841 (Liddon's *Life of Dr. Pusey,* iii.).

Practically all Anglican sisterhoods originated in works of mercy, and this fact largely accounts for the rapidity with which they have won their way to the good will and confidence of the Church. This change in sympathy, again, has gained a hearing from modern historians, who tend more and more to discredit the wholesale defamation of the dissolution period. Another modern feature is the fuller recognition of family ties: Rule 29 of the Clewer sisters directs that "the sisters shall have free intercourse with relations, who may visit them at any time." But in most essential respects modern sisterhoods follow the ancient traditions. They devote themselves to the celibate life, have property in common, and observe a common rule of prayer, fellowship and work. Government is by a sister superior, assisted by various officers. The warden and chaplain are clergy, and the visitor is commonly a bishop.

In one important regard there has been hesitation, and authorities like Dr. Littledale and Bishop Grafton contend strongly for the primitive ideal of the convent as family, with a constitutional government, as against the later and widespread Jesuit ideal of the convent as regiment, with a theory of absolute rule and obedience. On the other hand, the doctrine of obedience itself, as applied to Anglican Sisterhoods, is subject to the atmosphere of free institutions and a respect for individuals which are themselves correctives of any possible dangers, inherent in the principle.

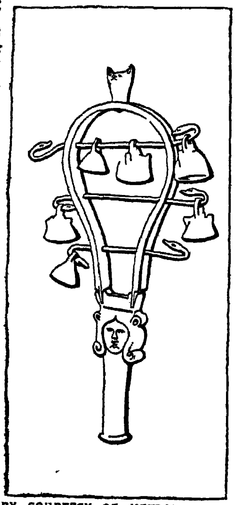
Inst.* (1870); Lina Eckenstein, *Woman under Monasticism* (1896); Mowbray, *Churchman's Year Book* (1929), ref. *s.v.* "Communities."

SISTOVA (Bulg. *Svishtov*), a town of Bulgaria, capital of the

department of the same name, on the Danube, 40 m. W. of Rustchuk. Pop. (1926), 12,068. A branch line connects it with the main Sofia-Rustchuk railway. It is an important commercial centre, exporting wine and grain and importing petroleum. The Roman colony *Novae,* mentioned by Ptolemy, lay a little westward of the present town, which has been destroyed and rebuilt many times (1797, 1810, 1829, 1878). The Treaty of Sistova, determining the Austro-Turkish boundary, was signed here (1790). Near by are the ruins of the palace of Theodoric the Goth. The Walachian town of Alexandria was founded by fugitives from Sistova in 1878.

SISTRUM, an ancient Egyptian instrument of percussion of indefinite musical pitch, a kind of metal rattle. It consisted of an oval metal frame fastened to a handle and crossed by four metal horizontal rods passing through holes large enough to allow them to rattle when the instrument was shaken. Queen Cleopatra made use of a large number of sistra at the battle of Actium (31 B.C.), and accordingly the instrument was satirically called Queen Cleopatra's war trumpet.

SISYPHUS (etymology uncertain), son of Aeolus and Enarete, and king of Ephyra (Corinth). He was the father of the sea-god Glaucus and (in post-Homeric legend) of Odysseus. He was said to have founded the Isthmian games in honour of Melicertes, whose body he found lying on the shore of the Isthmus of Corinth. From Homer onwards Sisyphus was famed as the craftiest of men. When Death came to fetch him, Sisyphus put him into fetters, so that no one died till Ares came and freed Death, and delivered Sisyphus into his custody. But Sisyphus was not yet at the end of his resources. For before he died he told his wife that when he was gone she was not to offer the usual sacrifice to the dead. So in the underworld he complained that his wife was neglecting her duty, and he persuaded Hades to allow him to go back to the upper world and punish her. But when he got back to Corinth he did no such thing and so lived until he died of old age (Pherecydes, frag. 119, Jacoby). In the underworld Sisyphus was compelled to roll a big stone up a steep hill; but before it reached the top of the hill the stone always rolled down, and Sisyphus had to begin all over again (*Odyssey,* xi. 593).



BY COURTESY OF METROPOLITAN MUSEUM OF ART

EGYPTIAN SISTRUM, USED BY PRIESTS IN THE TEMPLE OF ISIS

The way in which Sisyphus cheated Death is not unique in folktales. For several examples, *see* T. F. Crane, *Italian Popular Tales* (1885). The German parallel is Gambling Johnny, who kept Death up a tree for seven years, during which no one died (Grimm 82, *see* the commentary of Bolte-Polivka). The Norse parallel is the tale of the Master Smith (E. W. Dasent, *Popular Tales from the Norse*). For a Lithuanian parallel, *see* A. Schleicher, *Litauische Märchen, Sprichworte, Rätsel und Lieder* (1857); for Slavonic parallels, F. S. Krauss, *Sagen und Märchen der Südslaven,* ii., Nos. 125, 126; *see* also Frazer's *Pausanias,* iii., p. 33; O. Gruppe, *Griechische Mythologie* (1906), ii. p. 1021, note 2.

SITAPUR, a town and district of British India in the Lucknow division of the United Provinces. The town is on the river Sarayan, half-way between Lucknow and Shahjahanpur. Pop. (1921) 21,584. It is a cantonment, garrisoned by a portion of a British regiment. It has a considerable trade, principally in grain.

The DISTRICT OF SITAPUR has an area of 2,250 sq.m. It presents the appearance of a vast plain, well-wooded with numerous groves, and well cultivated, except in those parts where the soil is barren and cut up by ravines. Except in the eastern portion, which lies in the doabs between the Kewani and Chauka and the Gogra and Chauka rivers, the soil is as a rule dry, but even this moist tract is interspersed with patches of land covered with saline efflorescence called *reh.* The principal rivers are the Gogra, which is navigable by boats of large tonnage throughout the year, and the Chauka.

SITKA (formerly New Archangel), historically the most notable settlement of Alaska, on the west coast of Baranof island, in Sitka sound, lat. 57° 03′ N., 135° 19′ W., about 100m. S.S.W. of Juneau. Pop. (1890) 1,193 (300 white and 893 natives); (1930) 1,056. The city is prettily situated on an island-studded and mountain-locked harbour, with a background of forest and snow-capped mountain cones; an extinct volcano, Mt. Edgecumbe (3,467ft.), on Kruzof island, is a conspicuous landmark in the bay. Sitka's mean annual temperature is 2° higher than that of Ottawa, and its climate is more equable. The mean annual temperature is about 43° F; the monthly means range from 33° (January) to 56° (August), and the extreme recorded temperature from —4° to 87° F. Two-thirds of the days of the year are cloudy; on about 208 days in the year it rains or snows; the normal rainfall is 88·1in., the extreme recorded rainfall (in 1886) is 140·26 inches. The city includes an American settlement and an adjoining Indian village. In addition to United States Government buildings (naval coaling station, agricultural experiment station, wireless telegraph station and magnetic observatory), there are two public schools (one for whites and one for Thlinkets), the Sheldon Jackson (ethnological) museum, which is connected with the Presbyterian Industrial Training school, a parochial school of the Orthodox Greek (Russian) Church, a Russian-Greek church, built in 1816, and St. Peter's-by-the-Sea, a Protestant Episcopal mission built in 1899. Sitka is the see of a Greek Catholic and of a Protestant Episcopal bishop. In its early history it was the leading trading post of Alaska. After the discoveries of gold on the mainland, at the end of the 19th century, it lost its commercial primacy, but business improved after the discovery of gold in 1905 on Chicagoff island, about 50m. distant. There is a growing lumber industry; salmon fisheries are of greater importance. In the surrounding region there are gold and silver mines.

Old Sitka or Ft. Archangel Gabriel, about 6m. from the present town, was founded in May 1799. The fort was overwhelmed by the Thlinkets in 1802, but was recaptured by the Russians in Sept. 1804. The settlement was removed at this time by Alexander Baranof to the present site. Thereafter until 1867 it was the chief port and (succeeding Kodiak) the seat of government of Russian America. During the latter days of Russian occupation, Sitka presented a scene of splendour and activity. Here was located the Russian orthodox church of St. Michael with its spired dome and chime of bells, the courtly Baranof Castle, which was the residence of the Russian governor and the centre of social life, and the solidly built log warehouse of the Russian-American Fur company. It also had a shipyard and a foundry, which, it is said, made bells for half the mission churches in California. The formal transfer of Alaska from Russian to American possession took place at Sitka on Oct. 18, 1867. It continued to be the seat of government of Alaska until 1906, when Juneau became the capital.

SITMAR LINE. The "Sitmar" Steamship Company was originally incorporated with the Navigazione Generale Italiana. As an outcome of the deliberations of the Maritime Conventions, the lines of the N.G.I. which served the Mediterranean and Far East were formed into separate companies, which were subsidised by the State, and one of which was the "Sitmar" Company, whose vessels served Egypt, Syria and the Near East in competition with the Austrian and German companies.

In 1912 the "Sitmar" decided to construct new and faster vessels and to provide a more luxurious and comfortable mode of travelling to Egypt than their existing accommodation provided. The construction of two large steamers of 12,500 tons displacement was thereupon undertaken, and the whole of the Company's services were completely reorganized a short time before the World War broke out. Upon the outbreak of hostilities the Company's vessels were commandeered by the State for the transportation of troops in the Adriatic and Aegean Seas. Of the 13 vessels so taken, no fewer than 12, having a total tonnage of 62,000, were sunk by enemy vessels. At the cessation of hostilities it was found necessary to reorganize completely the entire service of the Company, and the reconstruction of vessels was begun on a large scale.

The launching of the well known S.S. "Esperia" took place in

1920. After placing the "Esperia" in the fleet the efforts of the Company were aimed especially at the establishment of a fast, regular service-de-luxe between Italy and Egypt, having weekly sailing from Genoa, at that time taken in turn by the S.S. "Esperia" and the S.S. "Italia."

In May 1926 the construction of a new vessel-de-luxe was commenced, the "Ausonia," to take the place of the S.S. "Italia": this vessel was launched in October 1927, and commenced running in 1928.

In addition to this regular weekly express service to Egypt by the fastest vessels in the Mediterranean, the "Sitmar" links up Italy with the principal ports of the eastern Mediterranean by the two fast "circular" lines, which provide a weekly sailing from Genoa to and from Egypt, Palestine, Athens, Constantinople and other ports.

In addition to these are the mail and commercial services of lesser importance: Fortnightly mail service, Tyrrhenian Sea–Danube; monthly commercial services, Tyrrhenian Sea–Aegean Sea and Tyrrhenian Sea–Black Sea.

The fleet of the "Sitmar" consists of 15 vessels, totalling 116,218 tons. (W. Sto.)

SITTIDAE: *see* Nuthatch.

SITTINGBOURNE, a market town in the Faversham parliamentary division of Kent, England, on a navigable creek of the Swale, 44¾ m. E.S.E. of London by the Southern Ry. Population (1931) 20,175 with Milton. It consists principally of one long street (the Roman Watling street) and the northern suburb of Milton Regis, a separate urban district (pop. 7,481), celebrated for its oysters, the fishery of which used to employ a large number of the inhabitants. Brick and cement making is an important industry employing about 6,000 hands, and there are corn and paper mills and a jam factory. The export trade in corn and import trade in coal is considerable. An earthwork known as Castle Rough, in the marshes below Milton, was probably the work of Hasten the Dane in 892, and Bayford castle, a mile distant, occupies the site of one said to have been built in opposition by King Alfred. Tong castle is about 2 m. E. of Sittingbourne. It consists of a high mound surrounded by a moat, and is said to have been erected by Hengest. Fragments of masonry exist about the mound. The story of the founding of the castle resembles that connected with the city of Carthage. Vortigern is said to have granted Hengest as much land as an ox-hide could encompass, and the hide being cut into strips the site of Tong castle was accordingly marked out. The same tradition attaches to Tong castle in Shropshire. Tradition also asserts, according to the 12th century chronicler, Geoffrey of Monmouth, that it was in Tong castle that Vortigern met Rowena, Hengest's daughter, and became so enamoured of her as to resign his kingdom to her father. In the time of Richard II. Tong castle belonged to Edmund Mortimer, earl of March.

Sittingbourne is mentioned in Saxon documents in 989 and frequently in contemporary records of the 13th and 14th centuries. The first charter was obtained in 1573; a second in 1599.

SITTING BULL (*c.* 1837–1890), a chief and medicine man of the Dakota Sioux, was born on Willow Creek, in what is now North Dakota, about 1837, son of a chief, Jumping Bull. He gained great influence among the reckless and unruly young Indians, and during the Civil War led attacks on white settlements in Iowa and Minnesota. Though he had pretended to make peace in 1866, from 1869 to 1876 he frequently attacked whites or Indians friendly to whites. His refusal to return to the reservation in 1876 led to the campaign in which Gen. George A. Custer (*q.v.*) and his command were massacred. Fearing punishment for his participation in the massacre, Sitting Bull with a large band moved over into Canada.

He returned to the United States in 1881, and after 1883 made his home at the Standing Rock Agency. Rumours of a coming Indian Messiah who should sweep away the whites, and Indian dissatisfaction at the sale of their lands, created such great unrest in Dakota in 1889–90 that it was determined to arrest Sitting Bull as a precaution. He was surprised and captured by Indian police and soldiers on Grand river Dec. 15, 1890, and was killed while his companions were attempting to rescue him.

SIVA (*Shiva*), in post-Vedic mythology the destroyer-god who with Brahma the creator and Vishnu the preserver forms the Indian trinity. In the Vedas *shiva* ("auspicious") was the epithet applied to any god, even euphemistically to the baleful Rudra (*q.v.*). In the Epic literature Siva has many attributes and various functions. He is lord of spirits (*bhūts*), protector of cattle (as Pāsupati) and god of letters, music and dancing. As Natarāja ("dance-king"), however, his worship is confined to southern India; and there, too, is to be found one of his peculiar sects, the Lingāyats (*q.v.*). His spouse is essentially Devi ("the goddess") under the various names, Umā, Pārvati, Durga (*q.v.*), Kālī (*q.v.*), or Karālī.

See W. E. Hopkins, *Epic Mythology* (Strasbourg, 1915); O. C. Gangoly, *South Indian Bronzes* (Calcutta, 1915).

SIVAJI (1627–1680), founder of the Mahratta power in India, was born in May 1627. He was the son of Shahji Bhonsla, a Mahratta soldier of fortune who held a *jagir* under the Bijapur government, and regarded himself as appointed to free the Hindus from the Mohammedan yoke. Forming a national party among the Hindus of the Deccan, he opposed in turn the vassal power of Bijapur and the imperial armies of the Mogul of Delhi. By intrigue and hard fighting, Sivaji won for the Mahrattas practical supremacy in western India. In 1659 he lured Afzul Khan, the Bijapur general, into a personal conference, and killed him with his own hand, while his men attacked and routed the Bijapur army. In 1666 he visited the Mogul emperor, Aurangzeb, at Delhi, but on his expressing dissatisfaction at not being treated with sufficient dignity, he was placed under arrest. Having effected his escape in a sweetmeat basket, he raised the standard of revolt, assumed the title of raja, and the prerogative of coining money in his own name. He died on April 5, 1680. Savaji had a genius both for war and for peaceful administration; but he always preferred to attain his ends by fraud rather than by force. He is the national hero of the Mahrattas.

See Grant Duff, *History of the Mahrattas* (1826); Krishnaji Ananta, *Life and Exploits of Sivaji* (1884); and M. G. Ranade, *Rise of the Maratha Power* (Bombay, 1900).

SIVAS, a vilayet in Asia Minor. Sivas (anc. *Megalopolis-Sebasteia*), altitude 4,420 ft., is the chief town of the vilayet of the same name. It is situated in the broad valley of the Kizil Irmak, on one of its right bank tributaries, the Murdan Su. Pop. (1927) 56,180. The climate is healthy but severe in winter. Coarse cotton cloth and woollen socks are manufactured. The *medresses* (colleges), built in the 13th century by the Seljuk sultans of Rum, are amongst the finest remains of Moslem art in Asia Minor. In one of them is the tomb of its founder, Izz ud-din Kai Kāus I. (1210–1219). Near the town is the Armenian monastery of the Holy Cross, in which are kept the throne of Senekherim and other relics. Under Diocletian Sebasteia became the capital of Armenia Minor, and in the 7th century that of the Sebasteia Theme. Justinian rebuilt the walls and, under the Byzantine emperors, it was second only to Caesarea in size and wealth. In 1021 Senekherim, king of the Armenian province of Vaspuragan (Van), ceded his dominions to Basil II., and became the Byzantine viceroy of Sebasteia and the surrounding country. This position was held by his successors until the town fell into the hands of the Turkomans after the defeat of Romanus II. by the Seljuks (1071). After having been ruled for nearly a century by the Danishmand amirs, it was taken (1172) by the Seljuk sultan of Rum, and in 1224 was rebuilt by Sultan Ala-ed-din Kaikobad I. In 1400, when captured by Timur, the city is said to have had 100,000 inhabitants, and to have been famous for its woollen stuffs. On this occasion the bravest defenders were massacred, and 4,000 Armenians were buried alive. Mohammed the "Conqueror" restored the citadel, and the place has ever since been an important Ottoman provincial capital. Early in the 19th century, like all other Ottoman towns, it was terrorized by janissaries, with whom Mahmud II. commissioned the great Dere Bey of Yuzgat, Chapan Oglu, to deal in 1818. The news of his drastic success provoked a dangerous riot in Stambul, which postponed by some years the final tragedy of the janissaries.

Mechithar, the founder of the Mechitharists (*q.v.*) and of the famous monastery at Venice, was born (1676) at Sivas. Sivas is connected with Angora by a railway which (in 1928) was being extended to Erzeroum.

SIVATHERIUM, an extinct mammal allied to the giraffe but larger, with two pairs of horns, the hinder large and deer-like, the anterior short and pointed. Its remains are found in the Pliocene foundation of the Siwalik hills in India. It reached a height of 7ft. An allied genus of the same geological age, *Samotherium,* with a single pair of horns, present only in the male, is known from Samos.

SIVRI-HISSAR, "Pointed-Castle," a kazah in the Eski Shehir vilayet in Asia Minor, situated 8 m. N. of the site of Pessinus, at the foot of a lofty double-peaked ridge of rock, which bears the ruins of a Byzantine castle. It is a road and commercial centre, with a trade in opium and mohair. Pop. (1927) 31,496. The town occupies the site of ancient *Palia,* re-founded and re-named Justinianopolis by the emperor Justinian. It was one of the chain of fortresses on the Byzantine military road across Asia Minor, and became the chief city of Galatia Salutaris about A.D. 700.

SIWA, an oasis in the Libyan Desert, politically part of Egypt. It is also known as the oasis of Ammon or Jupiter Ammon; its ancient Egyptian name was *Sekhet-am,* "Palm-land." The oasis lies about 350 m. W.S.W. of Cairo; its chief town, also called Siwa, being situated in 29° 12′ N., 25° 30′ E. The oasis is some 6 m. long by 4 to 5 wide. Ten miles north-east is the small oasis of Zetun, and westward of Siwa extends for some 50 m. a chain of little oases. The population of Siwa proper is nearly 4,000. The inhabitants are of Libyan (Berber) stock and have a language of their own, but also speak Arabic. The oasis is extremely fertile and contains many thousands of date palms. The town of Siwa is built on two rocks and resembles a fortress. The houses are frequently built on arches spanning the streets, which are narrow and irregular.

The oasis owes its distinction to the oracle temple of Ammon, which was already famous in the time of Herodotus, and was consulted by Alexander the Great. The remains of the temple are in the walled village of Aghormi, 2 m. E. of the town of Siwa. It is a small building, with inscriptions dating from the 4th century B.C. The oracle fell into disrepute during the Roman occupation of Egypt, and was reported dumb by Pausanias, *c.* A.D. 160. Near the temple are the scanty remains of another temple of the same century, Umm Beda, with reliefs depicting the prince of the oasis making offerings to Ammon, "lord of oracles." At Jebel Muta, 1 m. N.E. of Siwa, are tombs of Ptolemaic and Roman date; 10 m. E. of Aghormi is a well-preserved chapel, with Roman graves; at Kasr Rumi is a temple of the Roman period.

The oasis lies close to the Tripolitan frontier and is largely dominated by the sect of the Senussi (*q.v.*), whose headquarters were formerly at Jarabub, to the north-west. The Senussi successfully prevented various explorers penetrating westward beyond Siwa. The first European to reach Siwa since Roman time was W. G. Browne, who visited the oasis in 1792. There were serious disturbances in 1909, and as a result in 1910 a telegraph line was built across the desert from Alexandria to the oasis.

SIWALIK HILLS, a name given to the foot-hills of the Himalayas in Dehra Dun district of the United Provinces of India and in Nahan state and Hoshiarpur district of the Punjab. The range runs parallel with the Himalayan system from Hardwar on the Ganges to the Beas, with a length of 200 m. and an average width of 10 m. The elevation varies from 2,000 to 3,500 ft. Geologically speaking the Siwaliks belong to the tertiary deposits of the outer Himalayas, and are chiefly composed of low sandstone and conglomerate hills, the solidified and upheaved detritus of the great range in their rear. The intermediate valley lying between the outer hills and the Mussoorie mountains is known as the Dehra Dun (or Dehra valley) and is a popular residential area of Europeans and Anglo-Indians. The principal pass is that of Mohan by which the main road from Saharanpur to Dehra and Mussoorie traverses the range. The Siwalik formation (distinguished for its extraordinary wealth of palaeontological remains) is found on the North-west Frontier occupying much the same position relatively to the Suliman range as it does to the Himalayas, *i.e.,* it faces the plains and becomes the outermost wall of the hills.

SIWARD (d. 1055), earl of Northumbria, was a Dane by birth and probably came to England with Canute. He became earl of Deira after the death of Eadwulf Cutel, earl of Northumbria, about 1038, and earl of all Northumbria after murdering Eadwulf, earl of Bernicia, in 1041. He supported Edward the Confessor in his quarrel with Earl Godwine in 1051, and was appointed earl of Huntingdon soon after this date. In 1054 Siward invaded Scotland in the interests of his kinsman Malcolm Canmore, and he completely routed King Macbeth in a battle in which his son Osbeorn was killed. Early in 1055 the earl died at York. A man of unusual strength and size, he is said to have risen from his bed at the approach of death, and to have died dressed in all his armour. One of his sons was Earl Waltheof.

See E. A. Freeman, *The Norman Conquest,* vols. ii. and iii. (1870–76); and W. F. Skene, *Celtic Scotland* (1876–80).

SIXTUS, the name of five popes.

SIXTUS I. (Xystus) was the sixth bishop of Rome (*c.* 116–125) and took the name on that account. SIXTUS II., successor of Stephanus I. as bishop of Rome in 257, suffered martyrdom under Valerian on Aug. 6, 258. He restored the relations with the African and Eastern Churches which had been broken off by his predecessor on the question of heretical baptism. Dionysius succeeded him.

SIXTUS III. was bishop of Rome from July 31, 432, to Aug. 19, 440. Before his elevation to the pontificate he had been suspected of favouring the Pelagians, but when he became pope he disappointed their expectations, and repelled their attempts to enter again into communion with the Church. During his pontificate the dispute was settled between Cyril of Alexandria and John of Antioch, who had been at variance since the council of Ephesus, but he himself had some difficulties with Proclus of Constantinople with regard to the vicariate of Thessalonica. Sixtus IV. and Sixtus V. have separate notices. (L. D.)

SIXTUS IV. (FRANCESCO DELLA ROVERE), pope from Aug. 9, 1471, to Aug. 12, 1484, was born of a poor family near Savona in 1414. He entered the Franciscan order at an early age and studied philosophy and theology at the universities of Padua and Bologna. He was chosen general of his order in 1464. Three years later he was, to his own surprise, made cardinal-priest of St. Pietro in Vincoli by Paul II., whom he succeeded as pope. Sixtus sent Cardinal Caraffa with a fleet against the Turks, but the expedition was unsuccessful. He continued to condemn the Pragmatic Sanction in France, and denounced especially the ordinance of Louis XI. which required (Jan. 8, 1475) the royal *placet* for the publication of all papal decrees. He likewise continued his predecessor's negotiations with the Tsar Ivan III. for the reunion of the Russian Church with the Roman see and for support against the Turks, but without result. He was visited in 1474 by King Christian of Denmark and Norway, and in the following year (June 12) he established the University of Copenhagen. Sixtus soon abandoned his universal policy in order to concentrate attention on Italian politics, and showed himself a confirmed nepotist. He was cognizant of the conspiracy of the Pazzi, plotted (1478) by his nephew, Cardinal Riario, against Lorenzo de' Medici. He entered into a fruitless and inglorious war with Florence, which kept Italy for two years (1478–80) in confusion. He next incited the Venetians to attack Ferrara, and then, after having been delivered by their general, Roberto Malatesta, from a Neapolitan invasion, he turned upon them and eventually assailed them for refusing to desist from the hostilities which he had himself instigated. He relied on the co-operation of Lodovico Sforza, who speedily forsook him; and vexation at having peace forced upon him by the princes and cities of Italy is said to have hastened his death (Aug. 12, 1484). Sixtus granted many privileges to the mendicant orders, especially to the Franciscans; he endeavoured to suppress abuses in the Spanish Inquisition; he took measures against the Waldenses; he approved (1475) the office of the Immaculate Conception for Dec. 8; in 1478 he formally annulled the decrees of the council of Constance; and he canonized St. Bonaventura

(April 14, 1482). The most praiseworthy side of his pontificate was his munificence as a founder or restorer of useful institutions, and a patron of letters and art. He established and richly endowed the first foundling hospital, built and repaired numerous churches, constructed the Sistine chapel and the Sistine bridge, improved church music and instituted the famous Sistine choir, commissioned paintings on the largest scale, pensioned men of learning, and, above all, immortalized himself as the second founder of the Vatican library. These great works, however, were not accomplished without grievous taxation. Annates were increased and simony flourished.

Hayn (Cologne, 1896).
(C. H. H.; X.)

SIXTUS V. (Felice Peretti), pope from 1585 to 1590, was born at Grottamara, in Ancona, on Dec. 13, 1521. He was reared in extreme poverty; and at an early age he entered a Franciscan monastery. He soon gave evidence of rare ability as a preacher and a dialectician. About 1552 he came under the notice of Cardinal Carpi, protector of his order, Ghislieri (later Pius V.) and Caraffa (later Paul IV.), and from that time his advancement was assured. He was sent to Venice as inquisitor general, but carried matters with a high hand, became embroiled in quarrels, and was forced to leave (1560). After a brief term as procurator of his order, he was attached to the Spanish legation headed by Buoncampagno (later Gregory XIII.) 1565. The violent dislike he conceived for Buoncampagno exerted a marked influence upon his subsequent actions. He hurried back to Rome upon the accession of Pius V., who made him apostolic vicar of his order, and, later (1570), cardinal. During the pontificate of Gregory XIII. he lived in retirement, occupied with the care of his villa and with his studies, one of the fruits of which was an edition of the works of Ambrose; not neglecting, however, to follow the course of affairs, but carefully avoiding every occasion of offence. This discreetness contributed not a little to his election to the papacy on April 24, 1585.

The terrible condition in which Gregory XIII. had left the ecclesiastical States called for prompt and stern measures. Against the prevailing lawlessness Sixtus proceeded with an almost ferocious severity, which only extreme necessity could justify. Thousands of brigands were brought to justice: within a short time the country was again quiet and safe. Sixtus next set to work to repair the finances. By the sale of offices, the establishment of new "Monti" and by levying new taxes, he accumulated a vast surplus, which he stored up against certain specified emergencies, such as a crusade or the defence of the Holy See. Immense sums were spent upon public works; these include: the completion of the dome of St. Peter's; the loggia of Sixtus in the Lateran; the chapel of the Praesepe in Sta. Maria Maggiore; additions or repairs to the Quirinal, Lateran and Vatican palaces; the erection of four obelisks, including that in the piazza of St. Peter's; the opening of six streets; the restoration of the aqueduct of Severus ("Acqua Felice"); besides numerous roads and bridges, an attempt to drain the Pontine marshes, and the encouragement of agriculture and manufacture. But Sixtus had no appreciation of antiquity: the columns of Trajan and Antoninus were made to serve as pedestals for the statues of SS. Peter and Paul; the Minerva of the Capitol was converted into "Christian Rome"; the Septizonium of Severus was demolished for its building materials.

Sixtus limited the College of Cardinals to 70; and doubled the number of the congregations, and enlarged their functions, assigning to them the principal rôle in the transaction of business (1588). The Jesuits Sixtus regarded with disfavour and suspicion. He meditated radical changes in their constitution, but death prevented the execution of his purpose. In 1589 was begun a revision of the Vulgate, the so-called *Editio Sixtina.*

In his larger political relations Sixtus, strangely enough, showed himself visionary and vacillating. He distrusted Philip II. and viewed with apprehension any extension of his power. So, while he excommunicated Henry of Navarre, and contributed to the League and the Armada, he chafed under his forced alliance with Philip, and looked about for escape. The victories of Henry and the prospect of his conversion to Catholicism raised Sixtus's hopes, and in corresponding degree determined Philip to tighten his grip upon his wavering ally. The pope's negotiations with Henry's representative evoked a bitter and menacing protest and a categorical demand for the performance of promises. Sixtus took refuge in evasion, and temporized until death relieved him of the necessity of coming to a decision (Aug. 27, 1590).

Posterity ranks Sixtus one of the greatest popes. He was hasty, obstinate, severe, autocratic; but his mind was open to large ideas, and he threw himself into his undertakings with an energy and determination that often compelled success. Few popes can boast of greater enterprise or larger achievements.

Lives of Sixtus are numerous: Cicarella's, in Platina, *De vitis pontiff. Rom.,* is by a contemporary of the pope, but nevertheless of slight importance; Leti's *Vita di Sisto V.* (Amsterdam, 1693, translated into English by Farneworth, 1779) is a caricature, full of absurd tales, utterly untrustworthy, wanting even the saving merit of style; Tempesti's *Storia della vita e geste di Sisto Quinto* (1754–55) is valuable for the large use it makes of the original sources, but lacks perspective and is warped by the author's blind admiration for his subject; Cesare's *Vita di Sisto V.* (Naples, 1755) is but an abridgment of Tempesti. Of recent works the best are Hübner, *Sixte-Quint,* etc. (1870), translated into English by H. E. H. Jerningham (1872); and Capranica, *Papa Sisto, storia del s. XVI.* (Milan, 1884). *See* also Lorentz, *Sixtus V. u. seine Zeit* (Mainz, 1852); Dumesnil, *Hist. de Sixte-Quint* (1869, 2nd ed.); Segretain, *Sixte-Quint et Henri IV.* (1861, strongly Ultramontane); Ranke's masterly portrayal, *Popes* (Eng. trans., Austin), i. 446 *sq.,* ii. 205 *sq.;* and v. Reumont, *Gesch. der Stadt Rom,* iii. 2, 575 *sq.,* 733 *sq.* Extended bibliographies may be found in Herzog-Hauck, *Realencyklopädie, s.v.* "Sixtus V."; and *Cambridge Mod. Hist.* iii. 835 *sq. See* also *The Catholic Encyclopedia.*
(T. F. C.)

SIXT VON ARMIN, FRIEDRICH (1851–), German general, was born at Wetzlar, Nov. 27, 1851. He took part in the war of 1870–71 and was severely wounded at St. Privat. After having occupied different positions on the General Staff, he was appointed in 1903 Director of the General Department of War in the Prussian War Ministry, and in 1911 general-in-command of the IV. Army Corps at Magdeburg. During the World War he led his corps as a part of the First and of the Sixth Army; he was appointed in 1917 commander-in-chief of the Fourth Army in Flanders, where he succeeded, in the spring offensive in 1918, in taking Armentières and the Kemmel Hill. At the close of the war he retired from the army.

SKAGERAK, the arm of the North Sea which gives access to the Cattegat and so to the Baltic. It is about 140 m. long and 75 broad. On the Danish shore, which is low and beset with sandbanks, the strait is shallow. Towards the steep Norwegian coast its deepest part is found, 443 fathoms.

For the currents, temperature and salinity of the water, etc., *see* North Sea. For battle, *see* Jutland, Battle of.

SKAGWAY, a town of Alaska, situated at the north end of Lynn canal, a deep and narrow arm of the sea thrust far up between picturesque mountain ranges, in 59° 28′ N. and 135° 20′ W., is at the head of navigation in the waters of south-eastern Alaska. Skagway owes its present importance to being the seaward terminus of the White Pass and Yukon railway. This road, built in the years 1898–1900, extends up the valley of the Skagway river to the summit of White Pass, 20 m., crossing there the international boundary and continuing thence down on the Canadian side 90 m. to White Horse, head of navigation on the Yukon. Historically, it is of interest as the landing place of large quantities of supplies and many thousands of people during the struggle of 1897–98 (known as the "Klondyke Rush") to reach the newly discovered rich deposits of gold in the upper (Canadian) Yukon. Its population in 1930 was 492.

SKANDERBEG or **GEORGE CASTRIOTA** (1403–1468), the national hero of the Albanians, "ranked by Sir William Temple among the seven chiefs who have deserved, with-

out wearing a royal crown," was of Serbian origin. The founder of the family of Castriota was a certain Branilo, who was governor of Kanina in 1368, and whose grandson, Giovanni, lord of Mat and Vumenestia, married Voisava Tripalda, daughter of a Serbian magnate. The offspring of this union was George Castriota. Thus, as the Albanians gave to Greece several leaders of her War of Independence, Serbia furnished the chief figure of their struggle for freedom. George's uncle had, however, married an heiress of the leading Albanian clan of Thopia and thus acquired, together with the fortress of Kroja, some of that family's influence. Born in 1403, George was 11 years old when the Turks began to occupy Albania, and, while the castle of Kroja became the seat of a Turkish governor, he was sent as a hostage to Constantinople. Educated there as a Muslim he received the Turkish name of Iskander ("Alexander"), applied to him by Byron in *Childe Harold,* with the title of *bey*—subsequently abbreviated by his countrymen into Skanderbeg. Like Albanians in later times, he rose to eminence in the Turkish service; he was promoted to the government of a *sanjak,* and for many years fought for his Turkish masters against Venetians and Serbs, till, in 1443, while serving in the Turkish army which had been defeated by Janos Hunyadi's troops near Nish, he heard that his native land had risen against the Turkish garrison.

Then, at the age of 40, he realized that his mission was to free Albania, and the rest of his life was devoted to that object. Seizing Kroja by stratagem, he made it his capital, proclaimed himself a Christian, and gathered the wild Albanian clansmen about him. His personal influence was increased by his marriage with Andronica, daughter of Arianites Comnenus, a prominent Albanian chief, who had vainly endeavoured to drive out the Turks. The other chiefs rallied round his standard; the Montenegrins, whose ruler, Stephen Crnojevich, was his brother-in-law, came to his assistance, and at a gathering of the clans at the Venetian colony of Alessio he was proclaimed Captain-General of Albania. Venice, then mistress of the Albanian coast as far south as Durazzo, at first regarded him as a rival, but subsequently took him into her pay as an ally against the common foe. The pope and the king of Naples helped the Albanian cause, as fellow-Christians and neighbours, and the latter, mindful of the claims of the Neapolitan Angevins beyond the Adriatic, received the homage of the Albanian champion. But Mohammed II., partly by working upon the proverbial jealousy of the other Albanian chiefs, partly by force of arms, temporarily eliminated him, and in 1461 concluded with him a ten years' armistice.

But long before it elapsed, Skanderbeg, at the instigation of Pius II., broke it, with fatal results. That pope's projected crusade was prevented by its author's death; Skanderbeg, abandoned by his western allies, was left to fight single-handed against the great sultan, who himself in 1466 besieged Kroja. The fortress held out, but Skanderbeg went to seek help from Pope Paul II. in Rome, where a lane near the Quirinal still commemorates his name and visit. Returning, he died in the Venetian colony of Alessio on Jan. 17, 1468, whereupon the Turks easily conquered Albania, except Kroja, ceded by his son to Venice, and the other Venetian possessions. His son Giovanni and other Albanian chiefs emigrated to southern Italy, and his posterity formed part of the considerable Albanian colonies there; in our own time a self-styled Castriota claimed the Albanian throne on the ground of his alleged descent from the national hero.

Skanderbeg's grave in the church of St. Nicholas at Alessio was opened by the Turks, who touched his bones with superstitious reverence and wore them as amulets; but the ruins of the castle which he built on Cape Rodoni remain, the Mirdites still wear mourning for him, and the independent Albania of to-day has placed his image on some of her postage stamps. He has been made the subject of a Latin poem by de Bussières, an Italian poem by Signora Sarrocchi, and an English tragedy, *Scanderbeg: or Love and Liberty,* by Whincop (1747). Gen. Wolfe wrote that "he exceeds all the officers, ancient and modern, in the conduct of a small defensive army." His resistance to the Turkish advance helped Christendom, but did not save Albania—a country too small and too much divided by the clan system to stand against a powerful Turkey.

(W. M.)

SKARA BRAE, the name of sand-dunes, Parish of Sandwick, Orkney. About 1851 a great storm laid bare here an immense kitchen-midden and remains of ancient walls. Subsequent researches during the sixties by William Watt of Skail House, revealed a conglomeration of stone chambers or huts, opening onto a winding passage or street. Further excavations were conducted by Balfour Stewart in 1913, and in 1926 the Office of Works, which had assumed guardianship of the site, was obliged to initiate restoration works to preserve the monument against further encroachments by the sea. In the course of these operations J. Firth, the contractor, opened up a new hut in 1927 and in 1928 yet another hut and a large section of street were freed from superincumbent débris under the direction of Gordon Childe, Professor of Prehistoric Archaeology in Edinburgh University.

The prehistoric village is conveniently situated on the southern shore of the Bay of Skail, that offers a sheltered haven to fishermen and convenient landing-place for ancient mariners. It consists, as noted, of an agglomeration of huts built of dry-masonry. Up to date seven such huts have been identified, but one has been washed away by the waves and a second had been already ruined and abandoned before the desertion of the site in prehistoric times. The huts are roughly square but the corners are in every case rounded. The largest measures about 21 feet square on the floor while others are scarcely twelve feet across. The walls are built of slabs of local stone without mortar and converge towards the top, each course projecting inwards a little beyond the one below; in some cases, particularly in No. 7, they are still intact to a height of 10 feet. It does not seem possible, however, that they were completed to meet eventually in a corbelled dome, and it is still uncertain how the huts were roofed. In the walls at various heights niches have been left.

Moreover, most huts are provided with one or two small beehive cells, built in the thickness of the wall and entered by a low doorway. The floors of the huts were of stamped earth, but part at least was generally paved with slates. Huts 4 and 5, and probably also the others, were provided with drains, laid underneath the slate slabs and serving to carry off moisture and sewage. On the floors various domestic fixtures, being built of stone, still survive. In the centre in each case stands the hearth, framed with stone slabs set on edge. Built along the side walls are enclosures resembling pens formed by three large stone slabs set on edge and held in place by pins and uprights also of stone. Against the rear walls of huts 1 and 7 two-storeyed structures of stone resembling dressers have been reared. In all huts stand cubical slate-lined receptacles, sunk in the floor. The joints between the lining-slabs have always been carefully caulked with clay.

The hut-doors are low and narrow. The jambs are about two feet apart while the height from threshold to lintel seldom exceeds three feet. Immediately within the threshold comes a short passage or porch of only slightly ampler dimensions in the walls of which are holes for the bar that blocked the door to slide in. The entrance passage is always slate flagged.

The door opened on to a narrow street or passage, generally paved with slate and covered over about four feet above the floor with a roof of stone slabs. This street and its branches, of which only one is as yet known, provided the sole means of communication between the huts. The street-roofs are to-day covered over with a deposit of kitchen refuse. In this are found, together with ashes and broken animal bones, stone-knives, pot-sherds, bone implements and ornaments of precisely the same type as those collected on the floors of intact huts. Hence it is clear that

the people who lived in the huts used to dump their rubbish on the roofs of the streets connecting their dwellings and even to camp upon those roofs themselves.

The villagers of Skara Brae certainly possessed domestic animals including short-horned cattle, sheep and swine. There is no evidence that they practised agriculture, but fish played a prominent part in their diet and limpet shells have been found in enormous quantities. For weaving or metallurgy there is no evidence. Picks, shovels, awls (used probably for piercing leather garments), pins and polishing tools were made of bone. Flint, very finely worked, provided scrapers, and knives were manufactured in great numbers from the rolled stones of the beach. When dashed hard upon the ground these yield a sharp-edged flake quite suitable for use as a knife. Such flakes are extremely common in the midden and the huts. Axe-heads were made of polished stone and were not usually perforated. The only possible weapons, found on the site, are stone balls carved all over with nobby projections. These may have been mace-heads or bolas, but may equally well have served as poises for a weighing beam or bismar. The pottery is exceedingly coarse and very badly fired; indeed earthenware was used almost exclusively for cooking vessels, some of which are very large. The pots are nevertheless often decorated with relief patterns, formed by applied strips, below the rim. Other vessels include small cups made from vertebrae, large dishes of whale-bone and stone basins.

As ornaments, beads (disc, cylindrical, barrel-shaped and segmented) and amulets (generally in the form of a tusk or claw) carved out of bone, walrus-ivory, boars'-tusk and the incisor teeth of ruminants were popular.

The cemetery of Skara is yet to be found. One skeleton was unearthed lying above the hearth of hut No. 1 many years ago. In 1928 a double-interment was discovered under the wall of hut No. 7. This grave was an integral part of the hut and must have been covered over before the wall was built. It contained the skeletons of two very aged women which were buried in the contracted posture with a very poor type of furniture. They were probably the victims of a foundation sacrifice. The skeleton from hut No. 1 belonged to a tall woman, 5 ft. 6 in. high with a long head (index 70·6). The skull of the victim from hut No. 7 was likewise dolichocephalic. Hence the lowness of the doorways and passages was not due to the dwarfish stature of the huts' owners. Probably the low door and long covered streets were really designed to exclude drafts of cold air like the entrance-passage of an Esquimaux snow-hut or *igloo*.

The builders of Skara were most probably Picts. In any case the architecture of their houses, their industry and especially their ceramic art carry on a tradition that had been rooted in northern Scotland since neolithic times. The actual age of the settlement is open to dispute. The finely worked flints and polished stone axe-heads would point to a high antiquity. Yet in previous excavations the mould for an early Christian cross and a stone carved with Runic letters were unearthed somewhere on the site. In 1928 an inscription was noticed on a slab in front of the grave. The script is still undecipherable. These facts would all support a date between A.D. 600 and 800, a date by no means incompatible with the stone balls. None the less it must be noted that a broch on the opposite side of Skail Bay has yielded normal Iron Age relics all far in advance of the industry of Skara Brae, while the pottery distinctly resembles that of the late bronze age ("encrusted" type).

SKAT, a game of cards, much played in central and northern Germany. It is generally supposed to have been invented about 1817 by an advocate of the name of Hempel in Saxe-Altenburg. There is, however, some reason for believing that the game is of much earlier origin and was played by the Slav inhabitants of Saxe-Altenburg long before that date. In the home of the game of skat (Saxony and Thuringia) the old German single-ended cards are usually employed, while in north and south Germany French cards are ordinarily used. The German cards are 32 in number and of four suits: *Schellen* (bells), the equivalent of diamonds; *Roth* (red), hearts; *Grün* (green), spades; and *Eichel* (acorn), clubs. The eight cards of each suit are the seven, eight, nine, ten, *Wenzel* or knave, queen, king and ace. This arrangement denotes at once the value of the single cards, each following card being higher in value than the preceding; *i.e.,* hearts are higher than diamonds, spades than hearts, and clubs (the highest colour) takes spades, hearts and diamonds. Again, 8 takes 7, 9 takes 8 and 7; but the knave (called *Wenzel* or *Unter*) is an exception (*see* below).

The game is played by three persons; where four play, the dealer takes no part in the play though he shares in the winnings and losings of the opponents of the player. The cards are dealt from left to right—or (as skat players say) in the direction the coffee-mill is turned. After the cards have been shuffled and cut, the dealer first deals three cards to each player, then four and again three, laying aside two cards (the skat). Each player has now ten cards in his hand, which he arranges in suits. The Wenzel or knaves occupy a peculiar position. They are not regarded as colour cards, but are essentially trumps and take all other trumps. The player sitting to the left of the dealer is "first hand," and if he himself intends to make a game, invites the others to declare theirs, or if he wishes to reserve all rights to himself, simply says *"Ich bin vorn"*—"I have the lead," and then his next neighbour on the left has to offer a game. If this neighbour holds such cards as to give him no prospect of winning, he passes, and his neighbour to the left has the right to offer a game. If he in his turn passes, then the first hand is at liberty to determine the game or declare *"Ramsch"* (*see* below). But if the first neighbour thinks he can risk a game, he offers one. If the first hand reserves this game (*see* above, "I have the lead"), either because he intends to play it himself or to play a higher game, the second hand must go higher or pass, *i.e.,* renounce a game, and then his neighbour to the left has the right to offer, and if he again passes and does not offer a higher game than that which the first hand intends to play, the latter determines the game to be played.

The usual games in skat are the following. First the simple colour game, which is, however, seldom played by skat enthusiasts. The player has here the right to take up the skat, and to determine the suit of the game; but here the rule is that the colour must not be lower in value than that of the game offered, though it may be higher. For instance, if spades are offered, the player cannot take hearts as trumps, though he may take clubs, because they are higher in value than spades.

Next to the colour game comes "tourné," the player turning up one of the skat cards, the suit of which becomes trumps. If a knave be turned up the player may announce "grando." Then comes the game of "solo," where the player declares which suit shall be trumps, and the skat remains intact. The highest "solo," still higher than clubs, is "grando." In this game only the four knaves are trumps. If the hand playing grando thinks he can make all the tricks, he declares open grando; *i.e.,* shows his hand. If in open grando a single trick be lost, the player loses the game. If one of the players holds such cards as to enable him to force his opponents to take all the tricks, he can declare "nullo." But here the game is lost if even a single trick falls to the player. In nullo, the knaves are regarded as colour; *i.e.,* are not trumps. Nullo can be played open, if there is no probability of the player taking a single trick. Simple nullo counts higher than diamond solo; open nullo comes after clubs solo. In Ramsch, which takes place when none of the players will risk a game, each player takes (as in whist) all the tricks he makes—but only knaves are trumps—and the loser is he who makes most points. The value of the individual cards given in figures is as follows: the seven, eight and nine count nothing, the knave counts 2, the queen 3, king 4, ten 10 and ace 11 points. This gives the value of the whole game as 120 points. The game is won if the player gets one above the half of this sum, *i.e.,* 61. The hand that does not make 30 is "Schneider," that is "cut," and "Schwarz" (black) if he does not make a single point.

Skat is almost invariably played for money, and the calculation

is made thus. Every game and every suit have a set value:—

Colour game..... .3, 4, 5 and 6, according to the suits.
Tourné ... 5, 6, 7, 8 and 12 (the last the grando).
Solo.............. 9, 10, 11, 12 and 16 (grando).

These figures are increased by the number of "matadores." Suppose a player of club solo holds all four knaves and the ace and ten of clubs, he has a game with 6 matadores. By matadores is accordingly meant an uninterrupted sequence, *e.g.*, from the knave of clubs down to the seven of trumps. If the player has then all four knaves and all the cards of the trump suit in his hand (or in the skat), he has a game with 11 matadores. But if a single card is missing in the series, only the matadores of higher value than the missing card count. If, for instance, the knave of hearts is missing, the game in question has only three matadores. To the number of matadores is added one if the game is simply won, two if won with Schneider (cut), and four if the opponents are Schwarz (black). Thus, if a spade solo with five matadores is won with Schneider, the winner makes $5+2 \times 11=77$ points. (W. Da.)

AMERICAN SKAT

As prescribed by "The Laws of the North American Skat League," American skat differs from the European game. The cards are dealt in the following order: Beginning with the player at the dealer's left, three cards are dealt to each player, then two are dealt the skat; next four cards are dealt to each player, with a last round of three cards to each. Bids must be made in terms of the numerical value of some variety of game. "Passt-Mir-Nicht-Tournée" permits a player who dislikes the first card turned in the skat to reject that card without showing it, and to display the other skat card as the trump. If the exposed card be a jack, the player may choose its suit as the trump or he may elect to play a *grande tournée.* If the player utilizes the skat, neither "Schneider" nor "Schwarz" may be announced. Unannounced *Schneider* counts 2 points; unannounced *Schwarz,* 3 points. Announced *Schneider* counts 3 points, or in case *Schwarz* is made it counts 4 points. Announced *Schwarz* counts 5 points. A "grand" counts 20 points; a "grand ouvert" counts 24 points.

Although readily recognizable, the American nomenclature frequently differs from terms used in the European game: thus *grand* is often employed, instead of *grando; ouvert grand* replaces *open grando,* while *null* frequently supplants *nullo.* Almost invariably the word *jack* is used in place of *knave, wenzel* or *unter.* Except among those of foreign birth or close affiliation with those of foreign birth, the word *suit* is employed universally instead of the word *colour.* (E. V. S.)

SKATING, a mode of progression on ice with the aid of appliances called skates, attached to the sole of the shoe by straps, clamps or screws. The earliest form of skate that we know is that of the bone "runners" worn by the primitive Norsemen. These were bound to the foot with thongs. The Norse sagas speak with pride of the national achievements in skating, and the early development of the art was due principally to the Norsemen, Swedes, Danes, Finns and the Dutch. Whatever its origin in Great Britain, skating was certainly a common sport in England in the 12th century, as is proved by an old translation of Fitz-Stephen's *Description of London,* published in 1180, in which the following words occur:

"When the great fenne or moore (which watereth the walls of the citie on the North side) is frozen, many young men play on the yce . . . asome tye bones to their feete and under their heeles, and shoving themselves with a little picked staffe do slide as swiftlie as a birde flyeth in the aire or an arrow out of a cross-bow."

At what period the use of metal runners was introduced is unknown, but it was possibly not long after the introduction into northern Europe, in the 3rd century, of the art of working in iron. By the time of Charles II. skating had become popular, with the aristocracy as well as with the people, as is proved by entries in the diaries of Pepys and Evelyn.

The modern skate is in the form of a steel blade mounted upon a wood or metal base. In the old-fashioned skate the wooden base was strapped to the boot and kept firm by low spikes or screws that entered the sole. The next step in development was the "club-skate," originally Canadian, a patent appliance adjusted by clamps to fit the sole. There are several varieties of club-skates still popular. They have a broad blade with slightly curved edge, and are more suitable for figure-skating than for speed. The best skaters now use skates fixed permanently to special skating-boots.

As in ancient times, skating is most practised by the Scandinavians, Finns, Dutch and British, to whom in modern days have been added the Germans, Swiss, Austrians, Hungarians, French, Belgians, Italians, Japanese, Russians, Canadians and Americans. All these nations have "control" organizations, the British, founded in 1879, being the National Skating Association. The American, founded in 1884, is similarly styled, and co-operates with the Canadian Amateur Skating Association, founded in 1888. All are subject to the International Skating Union, the central body to which some 23 nations belong. In 1928 the U.S.A. Figure Skating Association transferred its membership of the I.S.U. to the Amateur Skating Union of the U.S.A.

Speed Skating.—Of the earliest skating races no records have been kept. That racing was a popular pastime in Holland two centuries and longer ago is proved by the numerous paintings of the time depicting racing scenes. In England the first skating match recorded was that in which Youngs of Mepal beat Thomson of Wimblingdon, both men of the Fens, in the year 1814. The Fen country has remained the chief English home of skating, owing to the abundance of ice in that district, and most British champions have been Fenmen, notably the Smarts of Welney. In Jan. 1823, according to the *N.S.A. Handbook,* the first amateur match took place between teams of six gentlemen from March and Chatteris, Drake of Chatteris finishing first. In the same year the *Sporting Magazine* records a match for a silver bowl on the Maze lake, Hertfordshire, over a course 5m. long, the winner being Blenkinsop. Racing, more or less intermittent, continued annually, the Fen skaters generally triumphing. In 1854 appeared the celebrated William ("Turkey") Smart, who, after defeating Larmen Register in that year, remained champion for more than a decade. His nephew, George ("Fish") Smart, won the championship in 1878 and held it until 1889, only to relinquish it to his younger brother James. The first amateur championship of England was held in 1880 at Hendon, and was won by F. Norman, a Fen skater.

Owing to the great area and cold winters of Canada and the northern United States, the sport of skating is indulged in to a great extent. Charles June was considered the best American skater from 1838 for many years, and his place of residence, Newburgh, N.Y., on the Hudson river, became the headquarters of American speed skating. This city also is the birthplace of the Donoghue family, who may be called the Smarts of America. The most noted members of this family were Mr. T. Donoghue and his two sons, Tim and J. F. Donoghue, each in his day the fastest skater in the world, Joseph Donoghue winning every event at the international championship meeting at Amsterdam in 1891. There is very little professional skating in America, and the only American who has appeared in important international races in recent years until the Olympiad of 1928 is C. Jewtraw, who won the 500 metres race in the Olympic skating at Chamonix in 1924.

Skating received a great impetus during the last decade of the 19th century, profiting both by the growing devotion to athletics and by increased facilities of communication, which led to international competitions and the institution of skating clubs in Switzerland and elsewhere, especially those of Davos, St. Moritz and Grindelwald, where ice is available every winter. Although skating instruments are so simple, the evolution of the skate has advanced considerably, contributing to marked improvement in the skater's skill. In speed-skating an epoch was marked, first, by the almost universal adoption of the Norwegian type of racing skate; and, secondly, by the institution in 1892, at an international congress held in Holland, of annual races for the championships of Europe and of the world.

The Norwegian skate, introduced and perfected (1887–1902) by

Axel Paulsen and Harald Hagen, is constructed with a view to lightness, strength and diminution of friction. The blade, of specially hardened steel, is set in a hollow horizontal tube of aluminium, and connected by similar vertical tubes with footplates riveted to a closely-fitting boot with thin leather sole. It is $16\frac{1}{2}$–19in. (42–48cm.) long, according to the height of the skater, and $\frac{1}{2}$–4mm. thick (*i.e.*, ·019–·157in.) the average employed for hard ice being $\frac{3}{4}$mm., often thinner towards the heel. This thickness is suitable for hard ice, but for softer ice $\frac{1}{16}$ or $\frac{1}{8}$in. is preferable. The blade is nearly flat on the ice throughout, except for a few inches in front; this flatness distributes the weight, and with the extreme thinness of blade, reduces friction to a minimum. At the same time the very slight curve to which the blades are built permits flexibility of stroke. This curve is such that when the blades are placed against each other, touching in the middle, the distance between them at the front stay should be about 1mm. and at the back about $\frac{1}{2}$mm. only. The edges are right-angled and should be kept sharp. A special machine has been invented for this purpose.

The skater's style has been modified. The blade, when planted on the ice with weight upon it, describes a nearly straight line, the last few feet only curving slightly outwards as the skate leaves the ice. Hence the stroke of the best skaters of the famous Peder Oestlund's period (*c.* 1900), was almost, if not entirely, on the inside edge, a gain in directness and speed, the outside edge being used for curves only. Since the World War there has been a tendency to revert to rather thicker blades than the very thin $\frac{1}{2}$mm.; making it possible to travel for several feet on the flat of the skate, or even on the outside edge as long as there is no appreciable weight yet transferred to that foot. This, however, at once increases the slight curve in the stroke, and the loss of directness must be compensated by more frequent striking. The

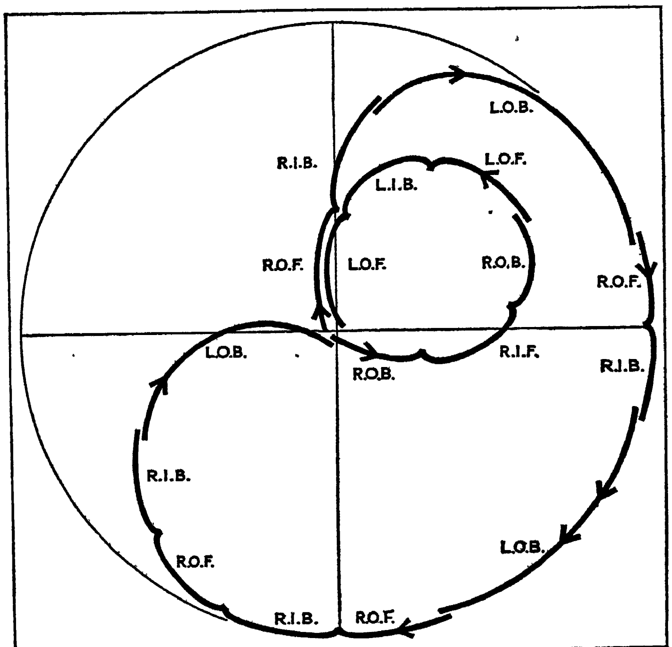

FIG. 1.—ENGLISH STYLE FIGURES SHOWING TWO REPRESENTATIVE COMBINED FIGURES SELECTED FOR THE NATIONAL SKATING ASSOCIATION'S FIRST-CLASS TEST
R=right foot: L=left foot: F=forward: B=back: I=inside edge: O=outside edge

length of stroke has tended on the whole to diminish. Contrasted with the 12–18 yards' stroke attributed to the old English champion, W. "Turkey" Smart, on the wooden fen "runner" which began decidedly on the outside edge, the modern racing stroke rarely exceeds 10yd., and is usually nearer 6 or 7. Particular instances vary with conditions of ice, etc., but at St. Petersburg, in 1896, Eden's stroke in the 10,000 metre race averaged about $7\frac{1}{2}$ yd., that of P. Oestlund at Davos, in 1900, the same (for one lap, 8yd.). J. F. Donoghue's stroke in 1891 was computed at about 9 yards. The general effect has been vastly increased speed, and a conjoint cause is the stricter training undergone before important races, together with the gradual improvement in skates and especially in race-courses.

The races held annually since 1892–93 for the championships of Europe and of the world, under the auspices of the I.S.U., have assembled representatives from the skating countries of Europe. The races are four in number, over distances of 500, 1,500, 5,000

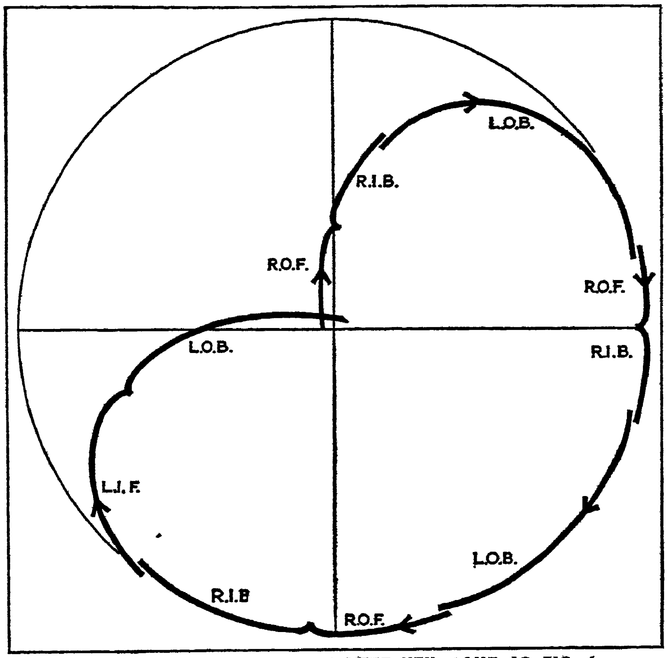

FIG. 2.—STYLE FIGURES; LETTER KEY, SAME AS FIG. 1

and 10,000 metres, and the winner at three or four distances becomes champion; failing this, the decision is by points on an elaborate system of marking. In addition, each country, when possible, holds its own championship races.

In England races are still skated, with rare exceptions, on straight courses, with a sharp turn round a post or barrel, the distance prescribed for N.S.A. championships being $1\frac{1}{2}$m., with three turns. The international system involves a course with straight sides and curved ends of such a radius that no slackening of speed is necessary. In both instances the competitors race two at a time on a double track, and the time test is used. Each skater must keep his own course, to prevent either from using the other as pacemaker or wind-shield. The international regulations (*Eiswettlauf-Ordnung*) prescribe that, if a single track be used, the hindmost skater must keep at a minimum distance of 5 metres from the other, on pain of disqualification. The advantage of inner curve on a Continental course is given alternately, and a space left open between the tracks at one point for the skaters to cross.

The curves are skated with a step-over-step action, and the direction is always from right to left. Hence, on entering the curve the right foot is brought across in front and set down on the inside edge, the left passing behind on the outside edge, and being in its turn set down on an outside edge in front. The strokes thus form a series of tangents to the curve, and are little shorter than in the straight. With a radius of 25 and 30 metres, as on the superb 400 metres racing track at Davos, the curves can be skated with safety at full speed.

The following are the amateur speed records at the principal distances:

Distance	m.	s.	Name	Nationality
500 metres (546·8yd.) .		$43\frac{3}{5}$	R. Larsen	Norway
1,000 metres (1,093·6yd.) .	1	$31\frac{4}{5}$	O. Mathiesen	Norway
1,500 metres (1,640·4yd.) .	2	$17\frac{2}{5}$	O. Mathiesen	Norway
5,000 metres (3 m. 188·2yd.)	8	$26\frac{5}{10}$	H. Strom	Norway
10,000 metres (6 m. 376·3yd.)	17	$17\frac{2}{5}$	A. Carlsen	Norway

The superiority of Norwegian skaters in world's championship races has been remarkable, Norway having provided 13 out of 24 winners between 1893 and 1928. On five occasions before the present system of points was adopted the result was indecisive, no skater winning three out of four races. Of these 13 victories no less than five stand to the credit of the Norwegian champion, Oscar Mathiesen, of Christiania (Oslo), who from 1914–27 was also holder of four out of five world's records for the usual distances. Holland has four victories to its credit (J. J. Eden three and De Koning one), Finland four (F. Wathén one and C. Thunberg three), and Russia two (N. Strunnikoff), while the only New World winner was T. McCulloch (Canada) when the championship was held at Montreal in 1897.

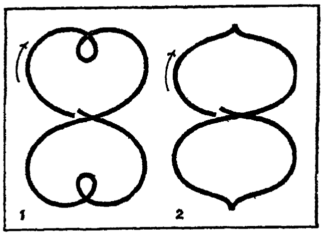

FIG. 3.—(1) LOOP-CHANGE-LOOP AND (2) BRACKET-CHANGE-BRACKET, SCHOOL FIGURES OF THE INTERNATIONAL SKATING UNION

Owing to the fickleness of the British climate, England, through lack of ice, has fallen behind in skill since the days of the Smarts, and practically the only Englishmen to compete in international races during the past 30 years have been C. Edgington, president of the Oxford University Speed Skating club, formed in 1895, which won the first representative race on skates between the universities on the duke of Marlborough's lake at Blenheim, defeating Cambridge in each of six races of 1 m. each, with three turns; F. W. Dix, British amateur champion in 1908–09 and 1912—the last year in which the championship was held up to 1928, winner of the Duddleston Cup (1m., 1908) and Baker Cup (220yd., 1912); and L. T. Redburn, winner of the 1m. amateur championship of London (1927). C. Edgington was second in each of the five international races at Davos (1901), fourth in two races (1,500 and 10,000 metres) in the world's championship at Berlin and in the European championship at Davos (1899), and in 1898 and 1899 twice beat the world's record for an hour's skating, accomplishing 18m. 1709yd. and 19m. 348yd., the latter standing for seven years till C. C. J. de Koning, Dutch world's champion (1905) made the present record, 20m. 207yd. The previous world's record was 18m. 215yd. by A. D. Smith (America) at St. Paul, Minn. (1894). In 1901, Edgington, at Davos, skated 10m. in 33min. 38$\frac{3}{5}$sec., beating the best English professional time of James Smart at Hamar (Norway) in 1891, viz., 35min. 10seconds. The best world's time for 10m. was made by J. S. Johnson (American amateur) at Montreal (1894), viz., 31 min. 11$\frac{1}{5}$ sec.

There are the American records (*see* Morgan-Browne, *Sporting and Athletic Records*), for short distances straight away, and with a wind behind, which show the speed attainable on ice with the help of a strong wind. Such are T. Donoghue, Jr.'s (American amateur) time of 2min. 12$\frac{3}{5}$sec. for 1 mile at Newburgh, N.Y. (1887), H. Davidson's 100yd. in 9sec. at Red Bank, N.J. (1895), H. Davidson and H. P. Moshier's 33$\frac{1}{5}$sec. for $\frac{1}{4}$m. (Orange lake, N.Y., and Red Bank, N.J., 1895), and J. F. Donoghue's 1min. 5$\frac{2}{5}$sec. for $\frac{1}{2}$m. with flying start (Newburgh, N.Y., 1892). Competition records (amateur) in America (outdoors) are: Jewtraw, 100yd., 9$\frac{2}{5}$sec.; Gorman, 440yd., 36$\frac{3}{5}$sec.; Thunberg, Finland, 880 yd., ($\frac{1}{2}$ mile) 1min. 15$\frac{1}{5}$sec.; Thunberg, 1 mile, 2min. 38$\frac{1}{5}$sec.

The best British time for 1m. is that of F. W. Dix, made on Cowbit Wash in 1912, without favour of wind, but with flying start, viz., 2min. 27$\frac{1}{5}$ seconds. In 1912 Dix, at Davos, won the 5,000 metres in 9min. 16$\frac{3}{5}$sec., and 10,000 metres in 18min. 49$\frac{2}{5}$sec., defeating the Austrian champion, T. Bohrer, and was second to the latter in the 1,500m. in 2 min. 33$\frac{1}{5}$ seconds. These are the best times made by an Englishman. On Dec. 31, 1927, on Lingay fen, near Cambridge, the British amateur championship was contested over a course of 1$\frac{1}{2}$m., with three turns, and was won by C. W. Horn (of Upwell, near Wisbech), in 4min. 55sec., with F. W. Dix (of Raunds, Northants), second. Dix had won this championship in Jan. 1908 in 4min. 37$\frac{2}{5}$sec., a time which remains the record. A thaw came before the professional championship could be decided. There had been no competitions for 15 years, and 25 men started, the oldest of whom was J. C. Aveling, champion in 1895 and on the next three occasions.

The world's speed championship for 1928 was decided on Feb. 4 and 5, at Davos, resulting in a narrow victory for C. Thunberg (Finland), who won but one race out of the four distances, each of which fell to a different man. Norwegians monopolized the next six places out of an entry of 31. The result was 1st, C. Thunberg, 193·87 points; 2nd, I. Ballangrud, 194·38; 3rd, B. Evensen, 194·86; 4th, R. Larsen, 195·68; 5th, M. Staksrud, 196·25; 6th, M. Mjelde, 196·41; 7th, A. Carlsen, 199·20. No Americans entered. Two young Englishmen were entered by the N.S.A. after a trial race of 1$\frac{1}{2}$m., in which they finished first and second respectively, C. W. Horn, amateur champion, and Spenser Edgington, but they naturally had no chance against the Norwegians and Finns. Horn skated very creditably in the 5,000 metres, accomplishing 9min. 32 sec., and beating two Dutchmen and a Lithuanian. New world's records for 500 and 10,000 metres were made respectively by R. Larsen (Norway), 43·1sec., and A. Carlsen (Norway), 17min. 17·4 seconds. Thunberg also won the European championship for 1928.

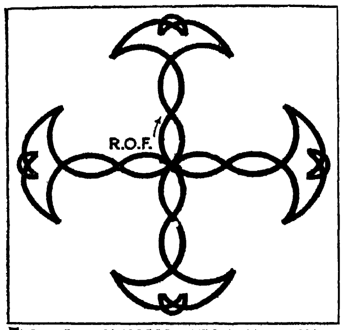

FIG. 4.—SPECIAL FIGURE SKATED BY MR. CUMMING AT PRINCE'S SKATING CLUB, LONDON, OCTOBER 1908
R.O.F. (direction for starting)

The Olympic speed skating was held at St. Moritz on Feb. 13 and 14, with 15 nations represented. The 500 metres was won by C. Thunberg (Finland) and B. Evensen (Norway), who skated a dead heat in 43·4sec., R. Larsen (Norway), J. Friman (Finland), and O. Farrell (U.S.A.), were bracketed for third place in 43·6sec. The 1,500 metres also fell to Thunberg in 2min., 21·1sec., Evensen being a fraction of a second slower, with I. Ballangrud third, R. Larsen fourth, followed by four Americans, E. Murphy, V. Bialas, I. Jaffee, and O. Farrell. The 5,000 metres was won by I. Ballangrud (Norway) in 8min. 50$\frac{1}{2}$sec., J. Skutnobb (Finland) being second, B. Evensen (Norway) third, I. Jaffee (U.S.A.) fourth, A. Carlsen (Norway) fifth, and V. Bialas (U.S.A.) sixth. The 10,000 metres race was spoilt by thaw, and had to be abandoned after four heats were attempted, although it was awarded to I. Jaffee (U.S.A.).

FIGURE SKATING

This artistic and fascinating class of skating, as subjected to definite rules, is quite modern, having originated in the 19th century, though the cutting of figures on the ice was regarded as an accomplishment by skaters long before.

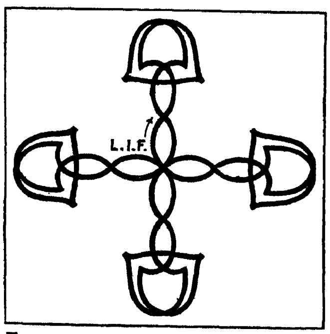

FIG. 5.—THE PANIN STAR SKATED BY MR. PANIN, A RUSSIAN, AT THE PRINCE'S SKATING CLUB IN THE OLYMPIC GAMES, OCTOBER 1908
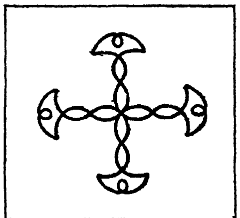
L.I.F. (direction for starting)

Although the Edinburgh Skating Club, founded probably in 1742, is the oldest skating organization in Great Britain, the Skating club, of London, formed in 1830, is the most important, and for many years practically controlled figure skating. Figure skating championships are held in many countries under the auspices of the national associations, the world's and European championship meetings having been held since 1896 and 1891, respectively, by the International Skating Union. In England great impetus has been given to figure skating by the multiplication of clubs, *e.g.*, Wimbledon, founded 1870, Thames Valley, Crystal Palace, and more recently the Figure Skating club, formed for the encouragement of the International style, the combined Figure Skating club, the Manchester S.C. and Combined F.S.C.,

the Kettering and District, Birmingham, Cambridge university and others, most of which are affiliated to the N.S.A., as well as those of Davos, St. Moritz, Château d'Oex, Engelberg, Wengen, Suvretta and the Bear S.C. at Morgins in Switzerland, the latter an enthusiastic nursery of the English style. Further valuable help has been derived from the construction of numerous artificial rinks, such as at Niagara, the National Skating Palace (known as Hengler's), Prince's club, Manchester Ice palace, and the new Ice club opened in London (Westminster) in 1926. To these must be added the Richmond (1928) and Grosvenor House (1929) rinks. The Richmond Ice Rink Club, on the Middlesex bank of the Thames, built at a cost of £80,000, was opened on Dec. 18, 1928, and has an artificial ice rink 286 ft. by 85 ft. (an area of 24,300 sq.ft.—the largest covered ice skating rink in the world). The periodical planing, scraping and sweeping of the ice surface is performed by electrical apparatus. The surface will accommodate 1,000 skaters, and speed skating is possible on a track of about eight laps to the mile. The N.S.A., which nearly to 1898 had supported exclusively the English style, has in recent years offered 1st, 2nd and 3rd class badges for figure tests in both English and International styles, as well as for speed; in 1893 the association founded a London Skating Council, while in 1898 and 1902 it held the figure skating championship of the world in London. In America comparatively little interest is shown in this branch of the sport.



THE ENGELMANN STAR
This figure was invented by E. Engelmann (Austria), champion of Europe in 1894

In the British style of figure skating, which is not recognized by the International Skating Union, the body is held as nearly as possible upright, the employed leg is kept straight, the unemployed leg carried behind, the arms hang loosely at the sides, and the head is turned as a rule in the direction of progress. In the so-called Anglo-Swiss style, affected by British skaters trained at Davos, St. Moritz, and other Swiss centres such as Morgins, the upright, almost rigid position is insisted on, even the unemployed leg being held straight. Much more latitude is allowed by the Continental school, though here too definite rules of form have been laid down. The knee of the employed leg is slightly bent, and the unemployed leg is in constant action, being used to balance the body during the execution of the figures. The Continental is less difficult in execution than the British style, but its movements are more graceful. There are, of course, local modifications. Canadians, whose Toronto Skating club is affiliated to the N.S.A., cultivate also grape-vines and other two-footed figures. The essential features are, however, identical. Thus Englishmen consider of secondary importance loops, cross-cuts, continuous and hand-in-hand skating (though such figures as grape-vines, single, double, Pennsylvania and Philadelphia are included in the 1st class test of the N.S.A.), and devote themselves mainly to "combined figures." Since 1901, however, the N.S.A., has devoted the English challenge cup to the encouragement of single skating in the English style, and since 1906 this competition has constituted the championship of Great Britain in that style. There was no contest for the years 1915–20; since then it was won for five out of seven years by R. S. Hewett, Bear S.C., and in 1928 by H. A. C. Goodwin.

Combined figures have been defined as "symmetrical execution of a figure by one or more pairs of skaters." Originally known as the "skating club figures," they have been gradually developed, and in 1882 a regular terminology was established, successively revised and extended by delegates from the principal clubs in 1891, 1903 and 1922. The ideal number of skaters for a combined figure is four, though sixes and eights are seen, one being chosen "caller" of the movement to be skated. Various sets of "calls" are arranged at the discretion of different clubs, and consist ordinarily of "turns" and "changes." The N.S.A. offer a challenge shield for an annual competition in combined figure skating, and a challenge cup was instituted in 1924 by the Bear S.C. won in 1928 by the Wimbledon S.C. In 1905 there was instituted a hand-in-hand competition for gentlemen and ladies, the winners of which hold a pair of salvers presented by Viscount Doneraile, president of the N.S.A. The winners the first two years this was held were A. J. Davidson and Miss D. R. Jameson, and in 1927, H. Whitehurst and Miss K. Lovett.

Though English style skating has flourished amazingly in recent years, the development of the international style in England and abroad since the beginning of the 20th century has been no less striking. In 1901 the Figure Skating club was established, as already stated, for this purpose, and its members attained such success that an English lady, Mrs. Syers, gained the second place in the world's championship competition in 1902, and with her husband won an international pair skating contest in that year, and again in 1904; and in 1906 and 1907, the first two years of its institution, she won the ladies' amateur championship of the world, or as it was styled previously to 1924, of the International Skating Union. The only English pair which has won the pair skating championship of the world (previously to 1924 styled the pair skating championship of the I.S.U.) is Mr. and Mrs. J. H. Johnson, also of the F.S.C., who were successful in 1909 at Stockholm and in 1912 at Manchester. This pair presented a trophy known as the Johnson challenge cup for a British pair skating championship in the international style, instituted by the N.S.A. in 1913, and won by themselves the first year, 1914, in 1921–22 by Major and Mrs. K. M. Beaumont, and from 1923–28 inclusive by J. F. Page and Miss E. Muckelt. The Swedish challenge cup, presented to the N.S.A. in 1902 by Col. Balck, president of the I.S.U., in the name of the Stockholm Allmänna Skridskoklub, was won by Mrs. Syers, in 1903 and 1904. In 1905 this was constituted the championship of Great Britain in the international style and was won by two other ladies, Mrs. Greenhough Smith in 1908 and 1911, and Mrs. Johnson in 1921. From 1922–28, inclusive, the holder was J. F. Page, who was fourth in the world's championship at Manchester in 1924, and third in 1925 to Herren Böckl and Dr. Preissecker, of Vienna, in Berlin, in an entry of nine, the greatest success that an English figure skater has ever attained. In 1927 the first competition for the challenge cup presented by H. M. Martineau for the championship of Great Britain in the international style for ladies was won by Miss K. Shaw (Manchester S.C.). In 1928 this was won by Miss C. Wilson (Toronto Skating Club), lady champion of Canada.

The world's figure skating championship was won in 1896 by G. Fuchs, Austria; 1897, G. Hügel, Austria; 1898, H. Grenander, Sweden; 1899 and 1900, G. Hügel, Austria; 1901–11 (inclusive, with the exception of 1906, when Dr. Fuchs was again the winner), U. Salchow, Sweden; 1912–13 and 1923, F. Kachler, Austria; 1914, G. Sandahl, Sweden; 1922 and 1924, G. Grafström, Sweden; 1925–27, W. Böckl, Austria; Böckl also won the European championship for 1928.

The competition consists of two parts, (*a*) compulsory figures (*Pflichtübungen*), (*b*) free skating (*Kürlaufen*), the latter affording scope for the performance of dance steps and brilliant individual figures, such as the "sitting pirouette," the spread-eagle (Mond), and the "star" consisting of four crosses (forward rocker, back loop, back counter), invented by Engelmann and splendidly rendered by Salchow.

The skates used for the English and international styles are shorter than those used for speed-skating, and differ in radius, though both are of the same type, *i.e.*, a blade fastened to the boot by sole-plates, the "Mount Charles" pattern being the one generally adopted by Englishmen. The English radius is 7ft., or in modern times more usually 6ft.; the foreign, 5½ or even 5ft., and the result is seen in the larger curves skated on the former, and the greater pace obtained owing to decreased friction; at the same time, the difficulty of making a turn is greater. The English skate has generally right-angled edges and blade of the same thickness throughout, except in the "Dowler" variety, which is thicker towards the extremities. The foreign skate is sometimes thicker in the middle than at the ends.

The Olympic figure skating championship was held at St. Moritz in Feb. 1928. The figure skating for men was won by G. Grafström (Sweden) for the third time, W. Böckl (Austria) being

second and Van Zeebroeck (Belgium) third. The ladies' event fell to Fröken Sonja Henie (Norway), Fräulein Fritzi Burger (Austria) being second, and Miss Beatrix Loughran (United States) third. The pair skating was won by the French pair, Mlle. Andrée Joly and Monsieur Pierre Brunet, Fräulein Lilli Scholz and Herr Otto Kaiser (Austria) being second, and Fräulein Melitta Brunner and Herr Ludwig Wrede (Austria) third.

The figure skating championship of the world for ladies and the pair skating championship of the world were held in March 1928, at the Ice club in London. This club, which has a membership of 1,500, was established on the lines of the Bath and Hurlingham clubs, and has a rink 170 by 90ft., with a 100ft. circle in the centre. The ice, 1½–2in. thick, is formed by the ammonia process, and there are no less than 8½m. of pipes. The ladies' championship of the world and the world's pair skating championship for 1928 resulted as follows: Ladies, 1st, Fröken Sonja Henie (Norway); 2nd, Miss Maribel Vinson (United States), afterwards winner of the ladies' championship of the U.S.A., and of the U.S.A. pair skating championship (with T. Coolidge); 3rd, Fräulein Fritzi Burger (Austria); 4th, Miss Constance Wilson (Canada); 5th, Fräulein Melitta Brunner (Austria); 6th, Miss Kathleen Shaw (England, Manchester Skating club). Pairs: 1st, Mlle. Andrée Joly and Pierre Brunet (France); 2nd, Fräulein Lilli Scholz and Otto Kaiser (Austria); 3rd, Fräulein Melitta Brunner and Ludwig Wrede (Austria); 4th, Miss Ethel Muckelt and J. F. Page (England, Figure Skating club); 5th, Miss Beatrix Loughran and Sherwin Badger (United States); 6th, Miss Maude Smith and Jack Eastwood (Canada); 7th, Mrs. J. W. Blanchard and N. W. Niles (United States); 8th, Miss K. M. Lovett and A. P. Burman (England, Manchester Skating club). (*See* also ROLLER SKATING.)

SKEAT, WALTER WILLIAM (1835–1912), English philologist, was born in London on Nov. 21, 1835, and educated at King's College School, Highgate Grammar School, and Christ's College, Cambridge, of which he became a fellow in July 1860. In 1878 he was elected Ellington and Bosworth Professor of Anglo-Saxon at Cambridge. His great work on Middle English literature includes the three parallel texts of *Piers Plowman* (1886), the Oxford edition of Chaucer (6 vols., 1894), with a supplementary volume of *Chaucerian Pieces* (1897), and important editions for the Early English and Scottish Text Societies. In pure philology Skeat's great work is his *Etymological English Dictionary* (4 parts, 1879–82; rev. and enlarged, 1910). In the publications of the English Dialect Society he had a hand as the founder of the society and afterwards its president. He died at Cambridge on Oct. 7, 1912.

SKEGNESS, a seaside resort in Lincolnshire, England; 131 m. N. by E. from London by L.N.E.R. Pop. (1931) 9,121. Since 1873, the place has undergone a transformation, and now possesses good hotels and a pier. There are broad, firm sands.

SKELETON. In most animals and plants, the shape could not be maintained without a thickening and hardening of certain parts to form a support for the whole. These hardened parts are the skeleton; they dry and remain after the rest of the body has disappeared. In higher animals the skeleton is always rendered more rigid and permanent by the deposit in it of lime salts, thus leading to the formation of bone. In most of the lower or invertebrate animals, the skeleton is on the surface and acts as a protection as well as a framework. This is an *exoskeleton.* In the higher or vertebrate animals there is an internal or *endoskeleton* and the exoskeleton is either greatly modified or disappears.

The following account is divided into (1) axial, or skeleton of the trunk, (2) appendicular or skeleton of the limbs, (3) visceral skeleton, or those parts which originally form the gill supports of water breathing vertebrates. The skull and exoskeleton are considered separately (*see* SKULL; SKIN AND EXOSKELETON).

Spine.—The SPINE, SPINAL or VERTEBRAL COLUMN, chine or backbone in man consists of superimposed bones named vertebrae. It lies in the middle of the back of the neck and trunk; has the cranium at its summit; the ribs at its sides, which in their turn support the upper limbs; whilst the pelvis, with the lower limbs, is jointed to its lower end. The spine consists in an adult of twenty-six bones, in a young child of thirty-three, certain of the bones in the spine of the child becoming ankylosed later. The bones of the spine are arranged in groups, named from their position, cervical, thoracic (formerly called dorsal), lumbar, sacral, and coccygeal or caudal; and the number of vertebrae in each group may be expressed in a formula. In man the formula is as follows:—$C_7Th_{12}L_5S_5Coc_4 = 33$ bones, as seen in the child; but the five sacral vertebrae fuse together into a single bone—the sacrum—and the four coccygeal into the single coccyx.

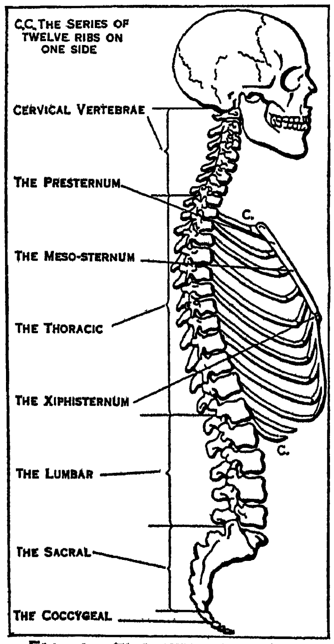

FIG. 1.—THE AXIAL SKELETON

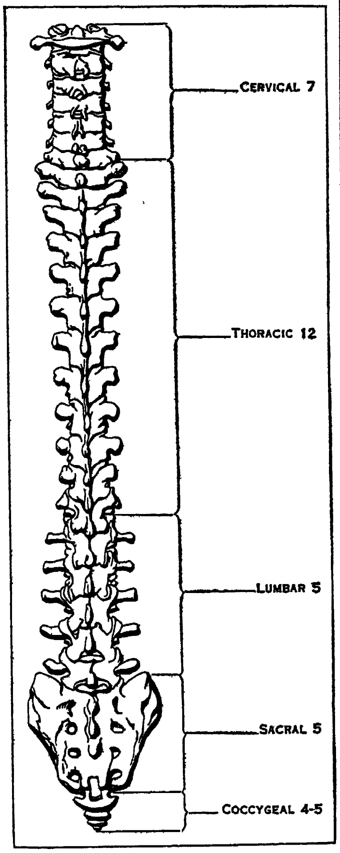
The vertebrae are irregularly-shaped bones, but have certain characters in common. Each possesses a body and an arch, which enclose a ring, with certain processes and notches. The body, or centrum, is a short cylinder, which by its upper and lower surfaces is connected by fibrocartilage with the bodies of the vertebrae immediately above and below. The arch encloses the spinal marrow or nervous axis, springs from the back of the centrum, and consists of two symmetrical halves united behind in the middle line. Each half has an anterior part or pedicle, and a posterior part or lamina. The processes usually spring from the arch. The spinous process projects backward from the junction of the two laminae, and the collective series of these processes gives to the entire column the character from which has arisen the term "spine." The transverse processes project outward, one from each side of the arch. The articular processes project, two upward and two downward, and are for connecting adjacent vertebrae. The notches, situated on the upper and lower borders of the pedicles, form in the articulated spine the intervertebral foramina through which the nerves pass out of the spinal canal. The vertebrae in each group have special characters.

Cervical Vertebrae.—In man and all mammals, with few exceptions, whatever be the length of the neck, the cervical vertebrae are seven in number. The first, or *atlas,* has no body or spine: its ring is very large, and on each side of the ring is a thick mass of bone by which it articulates with the occipital bone above and the second vertebra below. The second vertebra, *axis,* has its body surmounted by a thick, tooth-like *odontoid* process, which is regarded as the body of the atlas displaced from its proper vertebra

and fused with the axis. This process forms a pivot round which the atlas and head move in turning the head from one side to the other; the spine is large, thick and deeply bifid. The seventh is distinguished by its long prominent spine, which is not bifid, and by the small size of the foramen at the root of the transverse process. In the human spine the distinguishing character of all the cervical vertebrae is the foramen at the root of the transverse process.

Thoracic Vertebrae.—There are twelve of these in the human spine and all are distinguished by having one or two smooth surfaces on each side of the body for articulation with the head of one or two ribs. The transverse processes have an articular surface in front for the tubercle of a rib. The first thoracic vertebra is very like the seventh cervical; the twelfth has its lower articular processes shaped like those of a lumbar vertebra.



FROM ARTHUR THOMPSON IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 2.—VERTEBRAL COLUMN, SEEN FROM BEHIND

Lumbar Vertebrae.—These in man are five in number. They are the largest of the true vertebrae, especially in the centrum. The fifth lumbar vertebra has its body much deeper in front than behind and its spine is less massive.

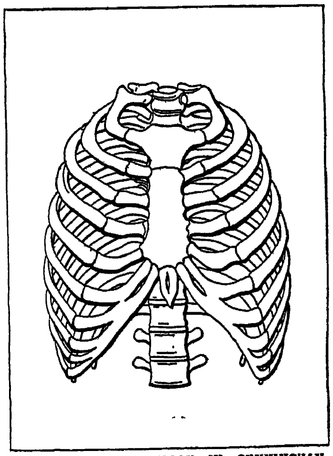
Sacrum.—The sacrum is composed of five originally separate vertebrae fused into a single bone. It forms the upper and back wall of the pelvis, is triangular in form, and possesses two surfaces, two borders, a base and an apex. The anterior or pelvic surface is concave, and is marked by four transverse lines, which indicate its original subdivision into five bones, and by four pairs of foramina, through which are transmitted the anterior sacral nerves. Its posterior surface is convex; in the middle line are four spines. On each side of these are two rows of tubercles, the inner of which are the conjoined articular and mammillary processes, the outer the transverse processes of the originally distinct vertebrae. Between these rows four pairs of foramina transmit the posterior sacral nerves from the sacral canal, which extends through the bone from base to near the apex, and forms the lower end of the spinal canal. By its borders the sacrum is articulated with the haunch-bones—by its base with the last lumbar vertebra, by its apex with the coccyx. The human sacrum is broader in proportion to its length than in other mammals; this great breadth gives solidity to the lower part of the spine, and, conjoined with the size of the lateral articular surfaces, it permits a more perfect junction with the haunch-bones, and is correlated with the erect position. Owing to the need in woman for a wide pelvis, the sacrum is broader than in man. (For details *see* A. M. Paterson, "The Human Sacrum," *Sci. Trans. R. Dublin Soc.* vol. v. ser. 2.)

Coccyx.—The coccyx consists of four or five vertebrae in the human spine though the last one is sometimes suppressed. It is the rudimentary tail, but instead of projecting back, as in mammals generally, is curved forward, an arrangement also found in the anthropoid apes and in Hoffmann's sloth. The vertebrae of which it is composed are small, and represent merely the bodies and transverse processes of the true vertebrae. There are no arches.

The human spine is more uniform in length in persons of the same race than might be supposed, variation in the height of adults being due chiefly to differences in the length of the lower limbs. The average length of the spine is 28 in.; its widest part is at the base of the sacrum, from which it tapers down to the tip of the coccyx. It diminishes also in breadth from the base of the sacrum upwards to widen again in the region of the neck. Behind and laterally it presents an irregular outline, but in front it is more uniformly rounded, owing to the convex form of the antero-lateral surfaces of the bodies of its vertebrae. In its general contour two series of curves may be seen, an antero-posterior and a lateral. The antero-posterior is the more important. In the infant at birth the sacro-coccygeal part of the spine is concave forward, but the rest of the spine is almost straight. When the infant begins to sit up, a convexity forward in the region of the neck appears, and subsequently, as the child learns to walk, a convexity forward in the region of the loins. Hence in the adult spine a series of convexo-concave curves are found, which are alternate and mutually dependent, and are associated with the erect attitude of man. A lateral curve, convex to the right, opposite the third, fourth and fifth thoracic vertebrae, with compensatory curve convex to the left immediately above and below, is due apparently to the greater use of the right arm. In disease of the spine its natural curvatures are much increased, and the deformity known as humpback is produced. As the spine forms the central part of the axial skeleton, it acts as a column to support not only the weight of the body, but of all that can be carried on the head, back and in the upper limbs: by its transverse and spinous processes it serves also to give attachment to numerous muscles, and the transverse processes of its thoracic vertebrae are also for articulation with the ribs.

Thorax.—The thorax, pectus or chest is a cavity, the walls of which are formed of bone and of cartilage. Its skeleton consists of the sternum in front, the twelve thoracic vertebrae behind, and the twelve ribs, with their corresponding cartilages, on each side.

Sternum.—The sternum or breast bone is an elongated bone which inclines downward and forward in the front wall of the chest. It consists of three parts—an upper, called manubrium or presternum; a middle, the gladiolus or mesosternum; and a lower, the ensiform process or xiphisternum. Its anterior and posterior surfaces are marked by transverse lines, which indicate not only the subdivision of the entire bone into three parts, but that of the mesosternum into four originally distinct segments. Each lateral border is marked by seven depressed surfaces for articulation with the seven upper ribs; at each side of the upper border of the presternum is a sinuous depression, where the clavicle articulates. The xiphisternum remains cartilaginous up to a late period of life.



FROM ARTHUR THOMPSON IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 3.—THE THORAX, SEEN FROM THE FRONT

Ribs.—The ribs or costae, twelve on each side of the thorax, consist not only of the bony ribs, but of a bar of cartilage continuous with the anterior end of each bone, called a *costal cartilage,* so that they furnish examples of a cartilaginous skeleton in the adult human body; in aged persons these cartilages usually become converted into bone. The upper seven ribs are connected by their costal cartilages to the side of the sternum, and are called *true ribs;* the lower five do not reach the sternum, and are named *false,* and of these the two lowest, from being comparatively unattached in front, are called *floating.* All the ribs are articulated behind to the thoracic vertebrae, and as they are symmetrical on the two sides of the body, the ribs in any given animal are always twice as numerous as the thoracic vertebrae in that animal. They form a series of osseo-cartilaginous arches, which extend more or less perfectly around the sides of the chest. A rib is an elongated bone, and as a rule

possesses a head, a neck, a tubercle and a shaft. The head usually has two articular surfaces, and is connected to the side of the body of two adjacent thoracic vertebrae; the neck is a constricted part of the bone, uniting the head to the shaft; the tubercle, close to the junction of the shaft and neck, is the part which articulates with the transverse process of the vertebra. The shaft is compressed, possesses an inner and outer surface, and an upper and lower border, but from the shaft being somewhat twisted on itself, the direction of the surfaces and borders is not uniform throughout the length of the bone. The ribs slope from their attachments to the spine, at first outward, downward and backward, then downward and forward, and where the curve changes from the backward to the forward direction an *angle* is formed on the rib. The angle and the tubercle are at the same place in the first rib and in each succeeding rib the angle is a little farther from the tubercle than in the last.

The surface of the first rib which is not in contact with the lung is directed upward, forward and outward while that of the second rib is much more outward; the eleventh and twelfth ribs are rudimentary, have neither neck nor tubercle, and are pointed anteriorly. The ribs increase in length from the first to the seventh or eighth, and then diminish to the twelfth; the first and twelfth are therefore the shortest ribs. The first and second costal cartilages are almost horizontal, but the others are directed upward and inward.

In its general form the chest is like a barrel which is wider below than above. It is rounded at the sides and flattened in front and behind, so that a man can lie either on his back or his belly. Its upper opening slopes downward and forward, is small in size, and allows the passage of the windpipe, gullet, large veins and nerves into the chest, and of several large arteries out of the chest into the neck. The base or lower boundary of the cavity is much larger than the upper, slopes downward and backward, and is oc-

FIG. 4.—TRANSVERSE SECTION OF A FERRET EMBRYO, SHOWING FURTHER DIFFERENTIATION OF THE MESODERM

cupied by the diaphragm (*q.v.*), which separates the chest from the abdomen. The transverse diameter is greater than the antero-posterior, and the antero-posterior is greater laterally, where the lungs are lodged, than in the mesial plane, which is occupied by the heart.

Embryology.—The first stiffening of the embryo is the formation of the *notochord*, which in higher vertebrates is temporary and is not converted into cartilage or bone. It is derived from the entoderm or inner of the three layers of the embryo while the bony skeleton is formed from the mesoderm or middle layer and, just as the entoderm is an older layer of the embryo than the mesoderm, so the notochord or entodermal skeleton precedes, both in embryology and in phylogeny or comparative anatomy, the bony mesodermal skeleton.

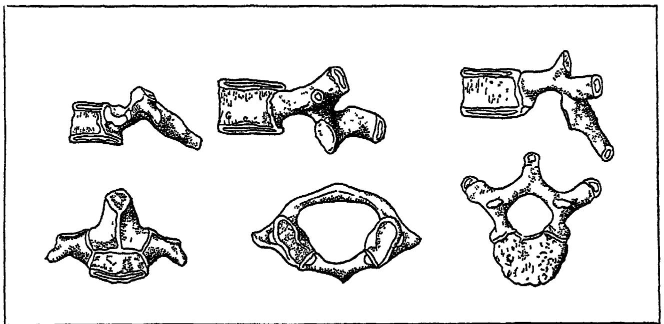
In the accompanying figure (fig. 4) the notochord is seen in section fully formed and lying between the entoderm and the neural canal. Its first formation is at an earlier period than this, before the neural groove has closed into a canal, and it appears at first as an upward groove from the most dorsal part of the entoderm in what will later on be the cervical region of the embryo. The groove, by the union of its edges, becomes a tube, but the cavity of this is soon obliterated by the growth of its cells, so that a solid elastic rod is formed which grows forward as far as the pituitary region of the skull and backward to where the end of the coccyx will be.

While the development of the notochord is going on the mesoderm on each side of it is dividing itself into a series of masses called *mesodermic somites* (see fig. 4, PS) or *protovertebrae*. This process begins in the cervical region and proceeds forward and backward until thirty-eight pairs have been formed for the neck and trunk and probably four extra ones for the occipital region of the skull. Each of these somites consists of three parts: that nearest the surface ectoderm is the cutaneous lamella (fig. 4, CL). Deep to this and separated in the earlier-formed somites by a space is the muscle layer (fig. 4, ML) while deepest of all and nearest the nerve cord and notochord is the *scleratogenous layer* (fig. 4, SL). It is this layer which gradually meets its fellow of the opposite side and encloses the nerve cord and the notochord in continuous tubes of mesodermal tissue, thus forming the *membranous vertebral column,* which is perforated for the exit of the spinal nerves, but the intervals between the successive mesodermic somites are still marked by the tissue being rather denser there. The next stage is conversion into cartilage of each segment of the membranous vertebral column surrounding the notochord. In this way the bodies of the cartilaginous vertebrae are formed and each of these is segmental, that is, it corresponds to a muscle segment and a spinal nerve. The cartilaginous neural arch, however, which surrounds the nerve cord is intersegmental and is formed in the denser fibrous tissue which separates each somite from the next. This also applies to the cartilaginous ribs which appear in the fibrous intervals (myocommata) between the muscle plates (myotomes), and so it is easy to realize that each typical rib must articulate with the bodies of two adjacent vertebrae, but with the neural arch, through its tranverse process, of only one.

The intersegmental tissue between the bodies of the vertebrae becomes the intervertebral discs and in the centre of these a pulpy mass is found which contains some remnants of the notochord. Elsewhere this structure is pressed out of existence and there is no further use for it when the cartilaginous vertebrae are once formed. One other series of structures must be mentioned though they do not play any great part in human development. In the intersegmental tissue ventral to each of the intervertebral discs a transverse rod of cells, known as a *hypochordal bar,* is formed which connects the heads of two opposite ribs. In man the greater number of these disappear, but in the case of the atlas the rod chondrifies to form the anterior (ventral) arch which is therefore intersegmental, while the segmental body of the atlas, through which the notochord is passing, joins the axis to form the odontoid process. These hypochordal bars are the last remnant in man of the haemal arch of the vertebrae of fishes (*see* subsection on comparative anatomy). In the cervical region the ribs form the ventral boundary of the foramen for the vertebral artery. They are so short that they become fused with the centrum and transverse process, leaving the vertebrarterial canal between. Sometimes in the seventh cervical vertebra the rib element is much longer and remains as a separate cervical rib with definite joints.

The sternum is developed according to G. Ruge by a fusion of the ventral ends of the ribs on each side thus forming two parallel longitudinal bars which chondrify and eventually fuse together in the mid line. The anterior seven or sometimes eight ribs reach the sternum, but the ventral ends of the ninth and sometimes the eighth probably remain as the xiphisternum. The morphological

meaning of the sternum and surrounding parts cannot be settled entirely by a study of their development even when combined with what we know of their comparative anatomy or phylogeny. Professor A. M. Paterson (*The Human Sternum,* London, 1904) takes



FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 5.—OSSIFICATION OF VERTEBRAE

a different view from the foregoing and regards the sternum as derived from the shoulder girdle. To this point of view we shall return in the section on comparative anatomy. The position of the vertebral and sternal centres of ossification is shown in figs. 5, 6 and 7. The ribs ossify by one primary centre appearing about the sixth week and by secondary ones for the tubercle and head. The sternum is ossified by centres which do not appear opposite the attachment of the ribs but alternately with them, so that although the original cartilaginous structure is probably intersegmental the bony segments are segmental like those of the vertebral centra.

For further details *see* C. S. McMurrich, *The Development of the Human Body* (London, 1923). This includes bibliography, but G. Ruge's paper on the development of the sternum (*Morph. Jahrb.* vi. 1880) is of special importance.

Comparative Anatomy.—Just as in development the notochord forms the earliest structure for stiffening the embryo, so in the animal kingdom it appears before the true vertebral column is evolved. This is so important that the older phylum of Vertebrata has now been expanded into that of Chordata to include all animals which either permanently or temporarily possess a notochord. In the subphylum Adelochorda, which includes the worm-like Balanoglossus, as well as the colonial forms Rhabdopleura and Cephalodiscus, an entodermal structure, apparently corresponding to the notochord of higher forms, is found in the dorsal wall of the pharynx. In the subphylum Urochorda or Tunicata, to which the ascidians or sea-squirts belong, the notochord is present in the tail region only and as a rule disappears after the metamorphosis from the larval to the adult form. In the Acrania, which are represented by Amphioxus (the lancelet) and are sometimes classed as the lowest division of the subphylum Vertebrata, the notochord is permanent and extends the whole length of the animal. Both this and the nerve cord dorsal to it are enclosed in tubes of mesodermal connective tissue which are continuous with the fibrous myocommata between the myotomes. Here then is a notochord and a membranous vertebral column resembling a stage in man's development.

FIG. 6.—OSSIFICATION OF SACRUM

(a, a) Centres for bodies, (b, b) Epiphysial plates on bodies, (c, c) Centres for costal elements, (d, d) Centres for neural arches, (e, e) Lateral epiphyses

In the Cyclostomata (hags and lampreys) the notochord and its sheath persist through life, but in the adult lamprey (Petromyzon) cartilaginous neural arches are developed. In cartilaginous ganoid fishes like the sturgeon, the notochord is persistent and has a strong fibrous sheath into which the cartilage from the neural arches encroaches while in the elasmobranch fishes (sharks and rays) the cartilaginous centra are formed and grow into the notochord, thus causing its partial absorption. Each centrum is deeply concave toward both the head and tail; such a vertebra is spoken of as *amphicoelous* and with one exception is always found in fishes which have centra. In the bony fish (Teleostei) and mudfish (Dipnoi) the vertebrae are ossified.

A vertebra from the tail of a bony fish like the herring has a ventral (haemal) arch surrounding the caudal blood-vessels and corresponding to the dorsal or neural arch which is also present. In the anterior or visceral part of the body the haemal arch is

FIG. 7.—OSSIFICATION OF THE STERNUM, SHOWING THE SECOND AS WELL AS THE THIRD SEGMENT OF THE BODY POSSESSING TWO CENTRES

split and its two sides spread out deep to the muscles and form the ribs. In the elasmobranchs on the other hand the ribs lie among the muscles as they do in higher vertebrates, and the fact that both kinds of ribs are coexistent in the same segments in the interesting and archaic Nilotic fish *Polypterus bichir* shows that they are developed independently of one another. The sternum is never found in fishes with the possible exception of the comb-toothed shark (Notidanus). Among the Amphibia the tailed forms (Urodela) have amphicoelous vertebrae in embryonic life and so have some of the adult salamanders, but usually the intercentral remnants of the notochord are pressed out of existence by the forward growth of the centrum behind it, so that in the adult each vertebra is only concave behind (opisthocoelous). In the Anura (frogs and toads), on the other hand, the centra are usually concave forward (procoelous) and some of the posterior ones become fused into a long delicate bone, the *urostyle.* The ribs of urodeles have forked vertebral ends and are thus attached to the centrum as well as to the neural arch of a vertebra; this forking is supposed to be homologous with the double ribs of Polypterus already referred to. The sternum as a constant structure first appears in amphibians and is more closely connected with the shoulder girdle than with the ribs, the ventral ends of which, except in the salamander Necturus, are rudimentary. It is not certain whether it is the homologue of the sternum of the fish Notidanus; the subject is discussed by T. J. Parker and A. M. Paterson (*The Human Sternum,* London, 1904, p. 50).

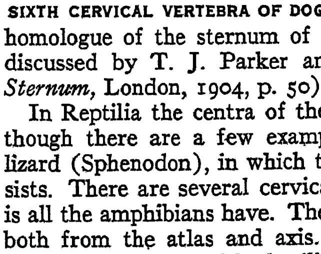

FIG. 8.—ANTERIOR SURFACE OF SIXTH CERVICAL VERTEBRA OF DOG

In Reptilia the centra of the vertebrae are usually procoelous, though there are a few examples, such as the archaic Tuatera lizard (Sphenodon), in which the amphicoelous arrangement persists. There are several cervical vertebrae instead of one, which is all the amphibians have. The odontoid bone is usually separate both from the atlas and axis. Two sacral vertebrae (*i.e.,* vertebrae articulating with the ilium) are generally present instead of the one of the Amphibia, but they are not fused together as in mammals. In the tail region haemal arches are often found enclosing the caudal artery and vein as in urodele amphibians; in

some species these are separate and are then spoken of as *chevron bones*. In the Crocodilia intervertebral disks first appear. Ribs are present in the cervical, thoracic and lumbar regions, and in the Chelonia (tortoises) the cervical ones blend with the vertebrae as they do in higher forms. In crocodiles a definite vertebrarterial canal is established in the cervical region which henceforward becomes permanent. The shafts of the ribs are sometimes all in one piece as in snakes or they may be developed by three separate centres as in Sphenodon with intervening joints.

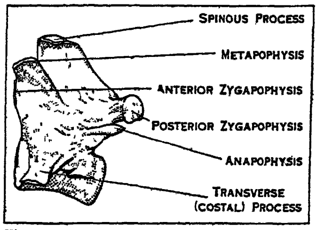

FIG. 9.—SIDE VIEW OF THE FIRST LUMBAR VERTEBRA OF A DOG

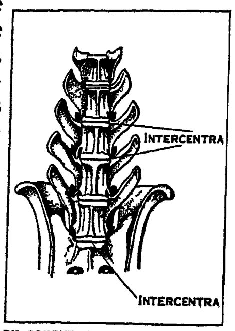
In Crocodilia and Sphenodon there are spurs from each thoracic rib which overlap the next rib behind and are known as *uncinate processes;* they are developed in connection with the origin of the external oblique muscle of the abdomen and are very constant in birds. The ventral elements of some of the hinder ribs are found in the Crocodilia lying loose in the myocommata of the rectus and obliquus internus (inscriptiones tendineae) and are known as abdominal ribs, while the sacral vertebrae articulate with the ilium through the intervention of short rods of bone, sometimes called *pleurapophyses,* which are no doubt sacral ribs. The sternum of reptiles is a broad plate of cartilage which may be calcified but is seldom converted into true bone; it always articulates with the coracoids (*see* section *Appendicular*) anteriorly and with a variable number of ribs laterally and posteriorly. It should not be confounded with the dagger-shaped interclavicle which, like the clavicles, is a membrane bone and overlaps the sternum ventrally.



BY COURTESY OF F. G. PARSONS AND THE ZOOLOGICAL SOCIETY OF LONDON

FIG. 10.—INTERCENTRA OF LOWER PART OF THE VERTEBRAL COLUMN

In birds the characteristics are largely reptilian with some specialized adaptations to their bipedal locomotion and power of flight. One effect of this is that the two true sacral vertebrae become secondarily fused with the adjacent lumbar, caudal and even thoracic, and these again fuse with the ilium so that the posterior part of a bird's trunk is very rigid. The neck, on the other hand, is very movable and the centra articulate by means of saddle-shaped joints which give the maximum of movement combined with strength (*see* JOINTS). The caudal vertebrae are fused into a flattened bone, the *pygostyle,* to support the tail feathers. In the fossil bird Archaeopteryx the centra are amphicoelous and the long tail has separate caudal vertebrae. The ribs are few and consist of dorsal and ventral parts; the former almost always have uncinate processes. Free cervical ribs are often present and Archaeopteryx possessed abdominal ribs. The sternum is very large and in flying birds (Carinatae) has a median keel (carina) projecting from it, while the non-flying, ostrich-like birds (Ratitae) have no such structure.

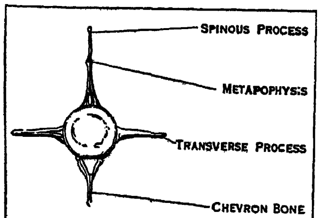


FIG. 11.—ANTERIOR SURFACE OF FOURTH CAUDAL VERTEBRA OF PORPOISE (PHOCAENA COMMUNIS)

In Mammalia the centra articulate by means of the intervertebral disks and it is only in this class that the epiphysial plates appear though these are absent in the Monotremata (duck-mole etc.) and Sirenia (sea-cows). The cervical vertebrae are with a few exceptions (two-toed and three-toed sloths and the manatee or sea-cow) always seven in number, and some, usually all, of them have a vertebrarterial canal in the transverse process. In some of the Cetacea they are fused together. In the Ornithorhynchus the odontoid is a separate bone, as in many reptiles, but this part includes the facets by means of which the axis and atlas articulate. The thoracic vertebrae vary from ten in some of the whales and the peba armadillo to twenty-four in the two-toed sloth, though thirteen or fourteen is the commonest number. In the anterior part of the thoracic region the spines point backward, while in the posterior thoracic and lumbar regions they have a forward direction. There is always one spine in the posterior thoracic region which is vertical, and the vertebra which bears this is known as the *anticlinal vertebra.* The lumbar vertebrae vary from two in the Ornithorhynchus and some of the armadillos to twenty-one in the dolphin, the average number being probably six. Both the mammillary and accessory tubercles are in some forms greatly enlarged. It is usually held that the former are morphologically muscular processes while the latter represent the transverse processes of the thoracic vertebrae. In the American edentates additional articular processes (zygapophyses) are developed, so that these animals are sometimes divided from the old-world edentates and spoken of as Xenarthra.

Lying ventral to the intervertebral disks in many mammals small paired ossicles are occasionally found; these are called *intercentra* and are ossifications in the hypochordal bar (*see* subsection on embryology). They probably represent the places where the chevron bones or haemal arches would be attached and are the serial homologues of the anterior arch of the atlas (*see* fig. 10); these intercentra, either as paired or median ossicles, are often found in lizards. The sacrum consists of true sacral vertebrae, which directly articulate with the sacrum, and false, which are caudal vertebrae fused with the others to form a single bone. There is also reason to believe that vertebrae which are originally lumbar become secondarily included in the sacrum because in the development of man the pelvis is at first attached to the thirtieth vertebra, but gradually shifts forward until it reaches the twenty-fifth, twenty-sixth and twenty-seventh; the twenty-fifth or first sacral vertebra, however, often reverts to the lumbar type and sometimes may do so on one side only.

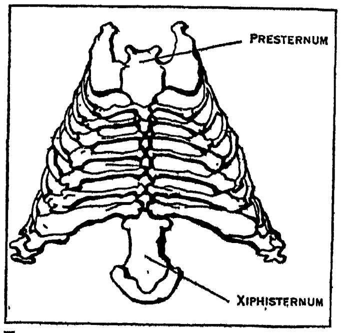

FIG. 12.—STERNUM AND STRONGLY OSSIFIED RIBS OF GREAT ARMADILLO (PRIODON GIGAS)

Taking the vertebrae which fuse together as an arbitrary definition of the sacrum, we find that the number may vary from one in *Cercopithecus patas* to thirteen in some of the armadillos, and, if the Cetacea are included, seventeen in the bottle-nosed dolphin, Tursiops. Four seems to be about the average in the mammalia and of these one or two are true sacral. In some of the Edentata the posterior sacral vertebrae are fused with the ischium, in other words the great sacro-sciatic ligament is ossified. The tail vertebrae vary from none at all in the bat Megaderma to forty-nine in the pangolin (*Manis macrura*). The anterior ones are remarkable for usually having chevron bones (shaped like a V) on the ventral surface of the intercentral articulation. These protect the caudal vessels and give attachment to the ventral tail muscles. The ribs in mammals correspond in number to the thoracic vertebrae. In typical pronograde mammals the shape of the ribs differs from that of the higher Primates and man: they are so curved that the dorso-ventral diameter of the thorax is greater than the transverse while in the higher Primates the thorax is broader from side to side than it is dorso-ventrally. In this respect the bats agree with man and the lemurs with the pronograde mammals.

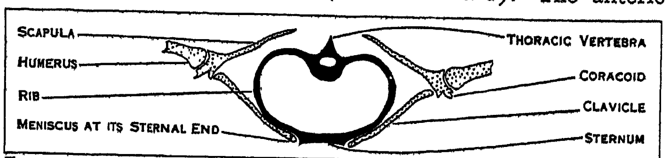

FIG. 13.—DIAGRAMMATIC SECTION REPRESENTING THE RELATIONS OF THE SHOULDER GIRDLE TO THE TRUNK

For further details and literature *see* S. H. Reynolds, *The Vertebrate*

Skeleton (Cambridge, 1897); W. H. Flower and H. Gadow, *Osteology of the Mammalia* (London, 1885); R. Wiedersheim, *Comparative Anatomy of Vertebrates,* adapted and translated by W. N. Parker (London, 1907); R. Wiedersheim and G. Howes, *The Structure of Man* (London, 1897); C. Gegenbaur, *Vergleich. Anat. der Wirbeltiere,* Band i. (Leipzig, 1901).

APPENDICULAR SKELETON

The bony framework of the upper and lower limbs is built up on the same plan in both. Each consists of a limb girdle connecting it with the axial skeleton, a proximal single bone segment, a distal double bone segment, the hand and foot segments and the digits (phalanges). It should be understood that in the following descriptions the terms internal and external are used in relation to the mid-line of the body and not to that of the limb.

Upper Limb.—The upper limb in man consists of a proximal part or shoulder, a distal part or hand, and an intermediate shaft, which consists of an upper arm, and a forearm. In each of these subdivisions certain bones are found: in the shoulder, the clavicle and scapula; in the upper arm, the humerus; in the forearm, the radius and ulna, the bone of the upper arm in man being longer than the bones of the forearm; in the hand, the carpal and metacarpal bones and the phalanges. The scapula and clavicle together form an imperfect bony arch, the Shoulder Girdle; the shaft and hand form a free divergent Appendage. The shoulder girdle is the direct medium of connection between the axial skeleton and the divergent part of the limb; its anterior segment, the clavicle, articulates with the upper end of the sternum, whilst its posterior segment, the scapula, approaches, but does not reach, the dorsal spines.

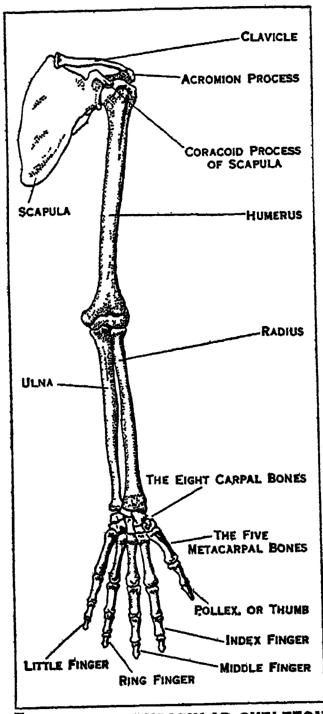

FIG. 14.—APPENDICULAR SKELETON OF LEFT UPPER LIMB

Clavicle.—The clavicle or collar bone (fig. 14) is an elongated bone which extends from the upper end of the sternum horizontally outward, to articulate with the acromion process of the scapula. It presents a strong sigmoidal curve, is slender in the female, but powerful in muscular males; its sternal end is thick and somewhat triangular; its acromial end, flattened from above downward, has an oval articular surface for the acromion. Its shaft has four surfaces for the attachment of muscles; and strong ligaments connecting it with the coracoid and the first rib.

Scapula.—The scapula or shoulder blade (fig. 14) is present in all mammals. It lies at the upper and back part of the wall of the chest, reaching from the second to the seventh rib. Its form is plate-like and triangular, with three surfaces, three borders and three angles. Its ventral surface is in relation to the ribs, from which it is separated by certain muscles: the dorsum is traversed from behind forward by a prominent *spine,* which subdivides this aspect of the bone into a *supra-spinous* and an *infra-spinous fossa.* The spine arches forward to end in a broad flattened process, the *acromion,* which has an oval articular surface for the clavicle; both spine and acromion are largely developed in the human scapula in correlation with the great size of the trapezius and deltoid muscles, which are concerned in the elevation and abduction of the upper limb. The borders of the scapula give attachment to several muscles. The angles are inferior, antero-superior and postero-superior. The antero-superior is truncated and has a large, shallow, oval, smooth surface, the *glenoid fossa,* for articulation with the humerus, to form the shoulder joint. Overhanging the glenoid fossa is a curved beak-like process, the *coracoid,* corresponding with the separate coracoid bone of monotremes, birds and reptiles.

Humerus.—The humerus (fig. 14) is a long bone, and consists of a shaft and two extremities. The upper extremity possesses a convex spheroidal smooth surface, the *head,* for articulation with the glenoid fossa of the scapula; it is surrounded by a narrow constricted *neck,* and where the neck and shaft become continuous with each other, two processes or *tuberosities* are found, to which are attached the rotator muscles arising from the scapular fossae. Between the tuberosities is a groove in which the long tendon of the biceps rests. The shaft is triangular in section above, but flattened and expanded below. A shallow groove winds round the back of the bone, in which the musculo-spiral nerve is lodged. The lower extremity consists of an articular and a non-articular portion. The articular has a small head externally for the radius, and a pulley internally for the movements of the ulna in flexion and extension of the limb. The non-articular part has projections on its inner and outer aspects, the *internal* and *external* condyles; each is surmounted by a *supracondylar ridge,* and the internal condyle and ridge attach the muscles passing to the flexor surface of the forearm, while the external are for those passing to the extensor surface.

Before describing the two bones of the forearm, the range of movement which can take place between them should be noticed. In one position, *supine,* they lie parallel to each other, the radius being the more external bone, and the palm of the hand being directed forward; in the other or *prone* position the radius crosses obliquely in front of the ulna, and the palm of the hand is directed backward. Not only the bones of the forearm, but those of the hand are supposed to be in the supine position when they are described.

Radius.—The radius (fig. 14) is the outer bone of the forearm, and possesses a shaft and two extremities. The upper extremity or *head* has a shallow, smooth cup for articulation with the humerus; the outer margin of the cup is also smooth, for articulation with the ulna and orbicular ligament; below the cup is a constricted *neck,* and immediately below the neck a *tuberosity* for the insertion of the biceps. The shaft of the bone possesses three surfaces for the attachment of muscles and a sharp inner border for the interosseous membrane. The lower end of the bone is much broader than the upper, and is marked posteriorly by grooves for the lodgment of tendons passing to the back of the hand: from its outer border a pointed *styloid* process projects downward; its inner border has a smooth shallow fossa for articulation with the ulna, and its broad lower surface is smooth and concave, for articulation with the scaphoid and semilunar bones of the wrist.

Ulna.—The ulna (fig. 14) is also a long bone. Its upper end is subdivided into two strong processes by a deep fossa which possesses a smooth surface for articulation with the humerus. The anterior process is rough in front for the insertion of the brachialis anticus, whilst the posterior or *olecranon* process gives insertion to the large triceps muscle of the upper arm. Immediately below the outer border of the great fossa is the *small sigmoid cavity* for articulation with the side of the head of the radius. The shaft of the bone has three surfaces for the attachment of muscles, and a sharp outer border for the interosseous membrane. The lower end, much smaller than the upper, has a pointed *styloid* process and a smooth articular surface, the outer portion of which is for the lower end of the radius, the lower part for moving on a cartilage of the wrist joint called the triangular fibro-cartilage.

Hand.—The hand consists of the carpus or wrist, the metacarpus or palm and the free digits, the thumb and four fingers. Anatomists describe it with the palm turned to the front, and with its axis in line with the axis of the forearm.

The *carpal* or *wrist* bones (fig. 14) are eight in number arranged in two rows, a *proximal,* consisting of the scaphoid, semilunar, cuneiform and pisiform, and a *distal,* consisting of a trapezium, trapezoid, os magnum and unciform; the bones in each row being named in the order they are met with, from the radial or outer to the ulnar or inner side of the wrist.

The *metacarpal* bones are five in number (fig. 14). They are miniature long bones, and each possesses a shaft and two extremities. The metacarpal of the thumb is the shortest, and diverges outward from the rest; its carpal extremity is saddle-shaped, for articulation with the trapezium; its shaft is somewhat compressed, and its phalangeal end is smooth and rounded, for the first phalanx of the thumb. The four other metacarpal bones belong to the four fingers. Their carpal ends articulate with the trapezoid, os magnum and unciform: their phalangeal ends articulate with the proximal phalanges of the fingers.

The number of *digits* in the hand is five. They are distinguished by the names of pollex or thumb, index, medius, annularis and minimus. Their skeleton consists of fourteen bones named phalanges, of which the thumb has two, and each of the four fingers three. Each is a miniature long bone, with two articular extremities and an intermediate shaft, except the terminal phalanges in which the distal end is rounded for the nail.

Lower Limb.—The lower limb consists of a proximal part or haunch, a distal part or foot, and an intermediate shaft subdivided into thigh and leg. Each part has its appropriate skeleton (the thigh-bone in man being longer than the leg-bones). The bone of the haunch (os innominatum) forms an arch or pelvic girdle, which articulates behind with the side of the sacrum, and arches forward to articulate with the opposite haunch-bone at the pubic symphysis. It is the direct medium of connection between the axial skeleton and the shaft and foot, which form a free divergent appendage.

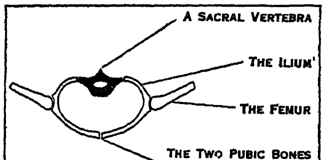

FIG. 15.—DIAGRAMMATIC SECTION SHOWING RELATIONS OF PELVIC GIRDLE TO THE TRUNK

The os innominatum, or haunch-bone, is a large irregular plate-like bone, which forms the lateral and inferior boundary of the cavity of the pelvis. In early life it consists of three bones—ilium, ischium and pubis—which unite about the twenty-fifth year into a single bone. These bones converge, and join to form a cup, the *acetabulum,* on the outer surface of the bone, which lodges the head of the thigh-bone at the hip-joint. At the bottom of the acetabulum is a depression, to the sides of which the ligamentum teres of the hip-joint is attached. From the acetabulum the ilium extends upward and backward, the ischium downward and backward, the pubis forward, inward and downward. Below the acetabulum is a large hole, the *obturator foramen,* which is bounded by the ischium and pubes; behind and above the acetabulum is the *deep sciatic notch,* which is bounded by the ischium and ilium, and below this is the *small sciatic notch.*

Ilium.—The ilium (fig. 16) in man is a broad plate-like bone, the lower end of which aids in forming the acetabulum, while the upper end forms the iliac crest, which, in man, is elongated into the sinuous crest of the ilium. This crest affords attachment to the broad muscles which form the wall of the abdominal cavity. One surface of the ilium is *external,* and marked by curved lines which subdivide it into areas for the origin of the muscles of the buttock; another is *anterior,* and hollowed out to give origin to the iliacus muscle; the third, or *internal,* surface articulates posteriorly with the sacrum, whilst anteriorly it forms a part of the wall of the true pelvis. The external is separated from the anterior surface by a border which joins the anterior end of the crest, where it forms a process, the *anterior superior spine.* Between the anterior and internal surfaces is the ilio-pectineal line, which forms part of the line of separation between the true and false pelvis.

Pubis.—The pubis (fig. 16) is also a three-sided, prismatic, rod-like bone, the fundamental form of which is obscured by the modification in shape of its inner end. In human anatomy it is customary to regard it as consisting of a *body* and of two branches, an upper and a lower *ramus.* Projecting forward from the junction of the body and upper ramus is the *pubic spine,* a landmark in surgery, and to this the ilio-pectineal line may be traced.

Ischium.—The ischium (fig. 16) also has the fundamental form of a three-sided prismatic rod. One extremity (the upper) completes the acetabulum, whilst the lower forms the large prominence, or *tuber ischii.* The tuberosity, a thick, rough and strong process, gives origin to several powerful muscles: on it the body rests in the sitting posture; a flattened ramus ascends from it to join the lower ramus of the pubis, and completes both the pubic arch and the margin of the obturator foramen.

Pelvis.—By the articulation of the two innominate bones with each other in front at the pubic symphysis, and with the sides of the sacrum behind, the osseous walls of the cavity of the pelvis are formed. This cavity is subdivided into a false and a true pelvis. The false pelvis lies between the expanded wing-like portions of the two ilia. The true pelvis lies below the two ilio-pectineal lines and the base of the sacrum, which surround the upper orifice or brim of the true pelvis, or pelvic inlet, whilst its lower orifice or outlet is bounded behind by the coccyx, laterally by the ischial tuberosities, and in front by the pubic arch. In the erect attitude the pelvis is so inclined that the plane of the brim forms with the horizontal plane an angle of from 60° to 65°. The axis of the cavity is curved, and is represented by a line dropped perpendicularly from the planes of the brim, the cavity and the outlet; at the brim it is directed downward and backward, at the outlet downward and a little forward. Owing to the inclination of the pelvis, the base of the sacrum is nearly 4 in. higher than the upper border of the pubic symphysis. The female pelvis is distinguished from the male by certain sexual characters. The bones are more slender, the ridges and processes for muscular attachment more feeble, the breadth and capacity greater, the depth less, giving the greater breadth to the hips of a woman; the inlet more nearly circular, the pubic arch wider, the distance between the tuberosities greater, and the acetabulum smaller in the female than in the male. The greater capacity of the woman's over the man's pelvis is to afford greater room for the expansion of the uterus during pregnancy, and for the expulsion of the child at the time of birth.

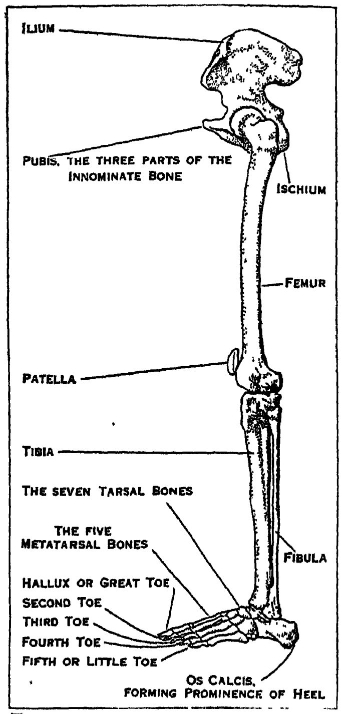

FIG. 16.—APPENDICULAR SKELETON OF THE LEFT LOWER LIMB

Femur.—The femur or thigh-bone (fig. 16) is the longest bone in the body, and consists of a shaft and two extremities. The upper extremity or *head* has a smooth hemispherical surface, in which an oval roughened fossa, for the attachment of the ligamentum teres of the hip, is found; from the head a strong elongated *neck* passes downward and outward to join the upper end of the shaft; the place of junction is marked by two processes or trochanters; to the *external* or *great trochanter* are attached many muscles; the *internal* or *lesser trochanter* gives attachment to the psoas and iliacus. A line drawn through the axis of the head and neck forms with a vertical line drawn through the shaft an angle of 30°; in a woman this angle is a little less obtuse, and the obliquity of the shaft of the femur is slightly greater. The shaft is almost cylindrical about its centre, but expanded above and below; its front and sides give origin to the extensor muscles of the leg; behind there is a rough ridge, which gives attachment to several muscles. The lower end of the bone presents a large smooth articular surface for the knee-joint, the anterior portion of which forms a *trochlea* or pulley for the movements of the patella, whilst the lower and posterior part is subdivided into two convex *condyles* by a deep fossa which gives attachment to the crucial ligaments of the knee.

The *femur* constitutes usually about 0·275 of the individual stature; but this proportion is not constant, as this bone forms a

larger element in the stature of a tall than of a short man. The human femur presents also a concave popliteal surface, thus differing from that of Pithecanthropus, whose popliteal surface is convex. In the bones of some races the dorsal ridge of the thighbone (linea aspera) projects as a prominent crest causing the bones to appear "pilastered." Pilastering, though characteristic of lower and primitive races of man, is never found in the anthropoids.

Patella.—The patella or knee-cap (fig. 16) is a triangular flattened bone developed in the tendon of the great extensor muscles of the leg. Its anterior surface and sides are rough, for the attachment of the fibres of that tendon; its posterior surface is smooth, and enters into the formation of the knee-joint.

Between the two bones of the leg there are no movements of pronation and supination as between the two bones of the forearm. The tibia and fibula are fixed in position; the fibula is always external, the tibia internal.

Tibia.—The tibia or shin-bone (fig. 16) is the larger of the two bones of the leg; the femur moves and rests upon its upper end, and down it the weight of the body in the erect position is transmitted to the foot. Except the femur, it is the longest bone of the skeleton, and consists of a shaft and two extremities. The upper extremity is broad, and is expanded into two *tuberosities,* the external of which has a small articular facet inferiorly, for the head of the fibula; superiorly, the tuberosities have two smooth surfaces, for articulation with the condyles of the femur; they are separated by an intermediate rough surface, from which a short *spine* (really a series of elevations) projects, which gives attachments to the interarticular crucial ligaments and semilunar cartilages of the knee, and lies opposite the intercondylar fossa of the femur. The shaft of the bone is three-sided; its inner surface is subcutaneous, and forms the shin; its outer and posterior surfaces are for the origin of muscles; the anterior border forms the sharp ridge of the shin, and terminates superiorly in a tubercle for the insertion of the extensor tendon of the leg; the outer border of the bone gives attachment to the interosseous membrane of the leg. The lower end of the bone, smaller than the upper, is prolonged into a broad process, *internal malleolus,* which forms the inner prominence of the ankle: its under surface is smooth for articulation with the astragalus; externally it articulates with the lower end of the fibula.

The tibia in most civilized races is triangular in the section of its shaft, but in many savage and prehistoric races it is two-edged. The foetal tibia has its head slightly bent backward with regard to the shaft, a condition which usually disappears in the adult, but is shown in the prehistoric tibiae found in the cave of Spy. In races that squat on their heels the front margin of the lower end of the tibia is marked by a small articular facet for the neck of the astragalus.

Fibula.—The fibula, or splint-bone of the leg (fig. 16), is a slender long bone with a shaft and two extremities. The upper end or *head* articulates with the outer tuberosity of the tibia. The shaft is four-sided and roughened for the origins of the muscles. Separating the anterior from the internal surface is a slender ridge for the attachment of the interosseous membrane. The lower end has a strong process (*external malleolus*) projecting downward to form the outer prominence of the ankle, and a smooth inner surface for articulation with the astragalus, above which is a rough surface for the attachment of ligaments which bind together the tibia and fibula.

Foot.—The foot consists of the tarsus, the metatarsus and the five free digits or toes. The human foot is placed in the prone position, with the dorsum or back of the foot directed upward; the axis of the foot at about a right angle to the axis of the leg; and the great toe or hallux, which is the corresponding digit to the thumb, at the inner border of the foot. The human foot, therefore, is a pentadactylous, plantigrade foot.

The bones of the tarsus or ankle (fig. 16) are seven in number, and are arranged in three transverse rows—a proximal, consisting of the astragalus and os calcis, a middle, of the scaphoid and a distal, consisting of the cuboid, ecto-, meso- and ento-cuneiform. The tarsal, like the carpal bones, are short and, with the exception of the cuneiforms which are wedge-shaped, irregularly cuboidal; the dorsal and plantar surfaces are as a rule rough for ligaments, but as the astragalus is locked in between the bones of the leg and the os calcis, its dorsal and plantar surfaces, as well as the dorsum of the os calcis, are smooth for articulation; similarly, its lateral surfaces are smooth for articulation with the two malleoli. The posterior surface of the os calcis projects backward to form the prominence of the heel. With this exception, the bones have their anterior and posterior surfaces smooth for articulation. Their lateral surfaces are also articular, except the outer surface of the os calcis and cuboid, which form the outer border; and the inner surface of the os calcis, scaphoid and the ento-cuneiform, which form the inner border of the tarsus. Supernumerary bones are occasionally found as in the hand.

The metatarsal bones and the phalanges of the toes agree in number and general form with the metacarpal bones and the phalanges in the hand. The bones of the great toe or hallux are more massive than those of the other digits, and this digit, unlike the thumb or pollex, does not diverge from the other digits, but lies almost parallel to them.

Embryology.—The development of the appendicular skeleton takes place in the core of mesenchyme in the centre of each limb. By mesenchyme is meant that part of the mesoderm, or middle layer of the embryo, in which the cells are irregularly scattered in a matrix, and are not arranged in definite rows or sheets as in the coelomic membrane. This substance first becomes changed into cartilage, except perhaps in the case of the clavicle.

The factors which determine the general shape and proportionate size of each limb bone are at work while the cartilage is being formed, because each future bone has a good cartilaginous model laid down before ossification begins. Calcification usually begins at one point in each bone, unless that bone be a compound one formed by the fusion of two or more elements which were distinct in lower vertebrate types, as is the case with the os innominatum.

Calcification, once established, acts as an attraction for blood-vessels, which probably bring with them osteoblasts, and the subsequent ossification is a process which needs and receives a plenteous supply of nourishment. After a long bone has reached a certain size it very often has extra centres of ossification (epiphyses) developed at its ends as well as at places where important muscles have raised lever-like knobs of cartilage on the model.

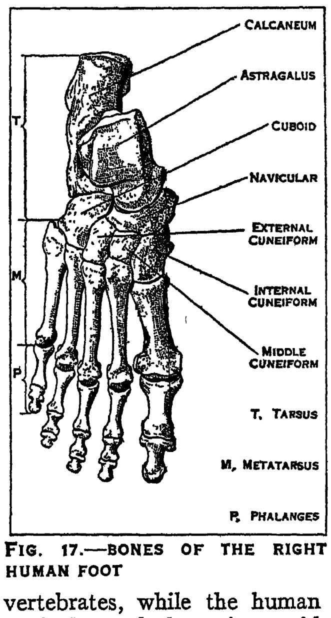

FIG. 17.—BONES OF THE RIGHT HUMAN FOOT

Turning now to the development of the individual bones of the axial skeleton, the clavicle is partly fibrous, and partly cartilaginous; its primary centre is the earliest of all in the body to appear, while its sternal epiphysis does not come till the bone is fully grown, and so can have no effect on the growth of the bone. It is probably atavistic, and is often regarded as the vestige of the precoracoid, though it may represent the inter-clavicle. It sometimes fails to appear at all.

The centres for the scapula are shown in the accompanying figures (fig. 19). G. B. Howes regarded the subcoracoid centre as the atavistic epiphysis representing the coracoid bone of lower vertebrates, while the human coracoid he looked upon as the equivalent of the epicoracoid. The epiphyses in the vertebral border are atavistic and represent the supra-scapular element (*see* section on *Comparative Anatomy*).

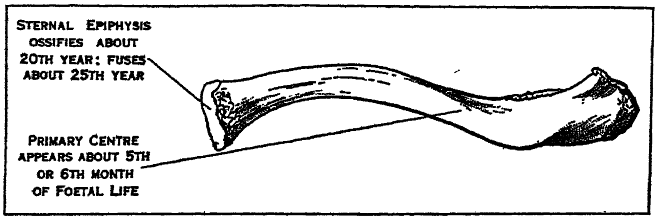
In the humerus the centre for the shaft appears about the eighth week of foetal life, which is the usual time for primary centres.

The ulna is a very interesting bone. The upper epiphysis shown

in fig. 21 does not encroach upon the articular surface, but is developed in the triceps tendon and is serially homologous with the patella in the lower limb.

In the radius there are two terminal epiphyses and one for the insertion of the biceps.

The carpus ossifies after birth, one centre for each bone occurring in the following order: os magnum, 11 to 12 months; unciform, 12 to 14 months; cuneiform, 3 years; semilunar, 5 to 6 years; trapezium, 6 years; scaphoid, 6 years; trapezoid, 6 to 7 years; pisiform, 10 to 12 years.



FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

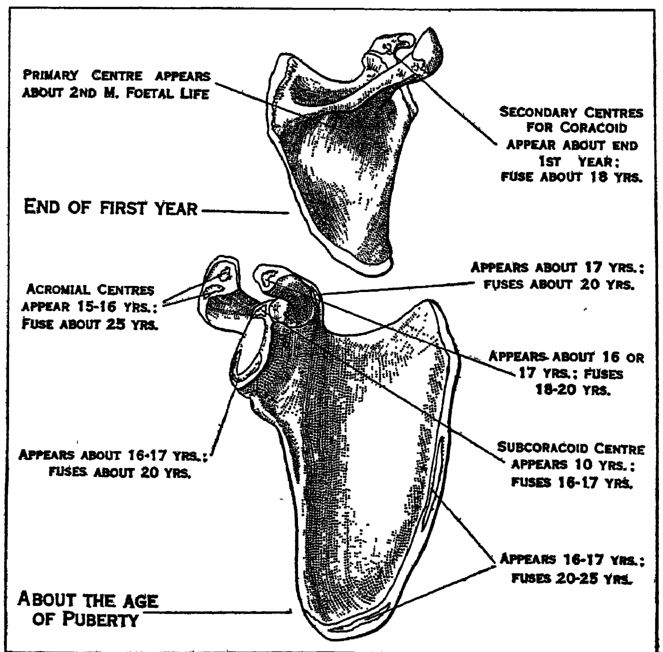
FIG. 18.—OSSIFICATION OF THE CLAVICLE

The metacarpal bones have one centre each for the shaft and one epiphysis for the head, except that for the thumb which has one centre for the shaft and one epiphysis for the proximal end.

The phalanges develop in the same way that the metacarpal bone of the thumb does.

The os innominatum has three primary centres for the ilium, ischium and pubis.

The special centres for the crest of the ilium are probably a serial repetition of those for the vertebral border of the scapula (*see* fig. 19). The centre for the pubic symphysis probably represents the epipubis of amphibians, while that for the tuberosity of the ischium is the hypoischium of reptiles (*see* subsection on comparative anatomy). The most anterior of the epiphyses in the acetabulum is the os acetabuli of lower mammals, while the occasional one for the spine of the pubis is often looked on as the vestige of the marsupial bone of monotremes and marsupials. It will thus be seen that many of the secondary centres of the os innominatum are atavistic.



FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

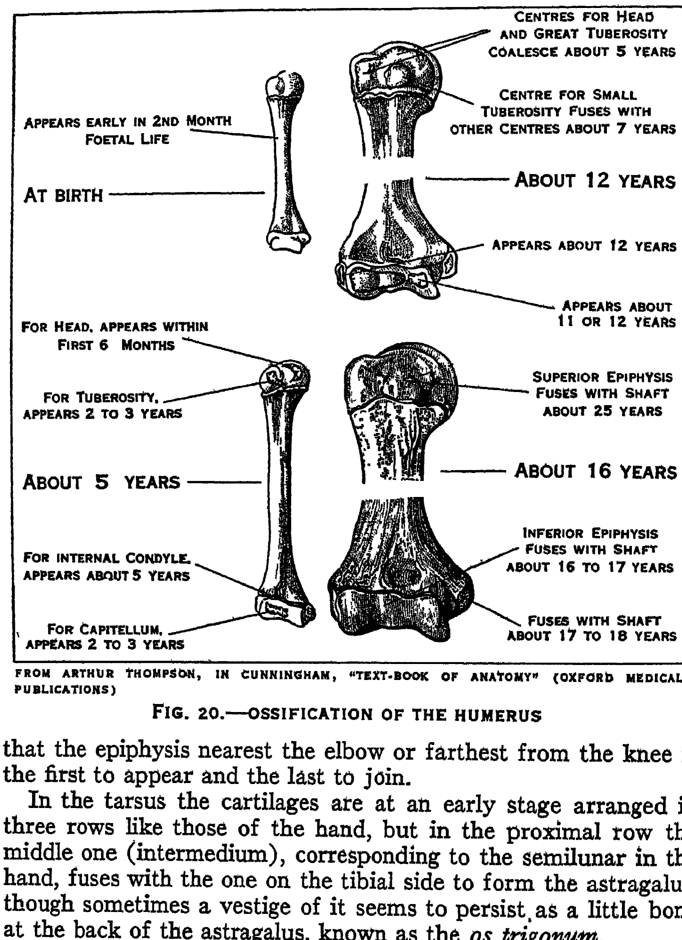
FIG. 19.—OSSIFICATION OF THE SCAPULA

The femur has epiphyses for the head, the lower end, the great and the small trochanters.

The cartilaginous patella does not appear until the third month of foetal life, that is well after the quadriceps extensor cruris, in the tendon of which it is formed, is defined. Its ossification begins in the third year. The patella is usually looked upon as the largest and most typical example of a sesamoid bone in the body.

The tibia has an epiphysis at either end, but that for the upper comes down in front so as to include a good deal of the tubercle. In almost any other mammal, and often in man himself, it may be seen that this down-growth is an epiphysis developed in the quadriceps tendon below the patella and joining the main upper epiphysis before uniting with the diaphysis or shaft.

The fibula has two epiphyses, the lower of which appears first. The general rule with the long bones of the extremities is that the epiphysis nearest the elbow or farthest from the knee is the first to appear and the last to join.



FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 20.—OSSIFICATION OF THE HUMERUS

In the tarsus the cartilages are at an early stage arranged in three rows like those of the hand, but in the proximal row the middle one (intermedium), corresponding to the semilunar in the hand, fuses with the one on the tibial side to form the astragalus, though sometimes a vestige of it seems to persist as a little bone at the back of the astragalus, known as the *os trigonum*.

The centre for the calcaneum appears in the sixth month of foetal life, that for the astragalus in the seventh, the cuboid about birth, the external, middle and internal cuneiforms in the first and second years, while the navicular is the last to appear in the third year.

The calcaneum has an epiphysis developed in the insertion of the tendo Achillis behind.

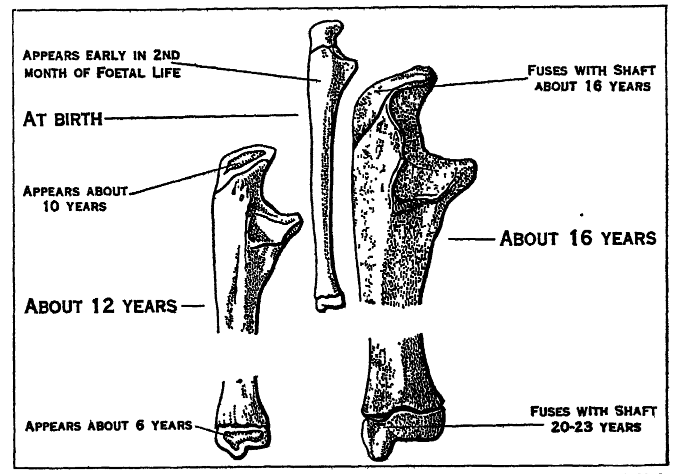
The development of the metatarsal bones and phalanges of the foot is the same as that of the hand.

For further details and literature *see* J. P. M'Murrich's *Development of the Human Body* (London, 1923) and D. J. Cunningham's *Text-Book of Anatomy*.

Comparative Anatomy.—It is only when the class of pisces is reached that paired appendages are found, and there are two main theories to account for their first occurrence. The one which is at present most favoured is that in some ancestral fishes two folds ran along the ventro-lateral part of the body, like the bilge keels of a boat, and that these joined one another in the mid-ventral line behind the cloacal orifice to form the median caudal fin. Into these folds the segments of the body, including myotomes and myocommata, extended. Later on parts of these ridges were suppressed, but in the pectoral and pelvic regions they were retained to form the paired fins. This theory is supported by the fact that in some elasmobranch embryos the whole length of

the folds can be traced. The second theory is that the limbs are elaborated gills. It is probable that the limb girdles are of later evolution than the skeleton of the fins themselves.

In the elasmobranch fishes (sharks and rays) there is a crescentic bar of cartilage (*pectoral girdle*), concave upward, which girdles the ventral and lateral parts of the body; it is divided into a dorsal part (scapula) and a ventral part (precoracoid and coracoid) by a facet for the articulation of the fin. This of course is the glenoid cavity. In some forms, *e.g.*, the shark Heptanchus, there is a perforation in the ventral part of the bar on each side, which possibly indicates the division between the precoracoid and coracoid elements.



FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 21.—OSSIFICATION OF THE ULNA

In many of the bony fish (Teleostei) the outline is obscured by a series of bones which connect the girdle with the skull and may be the precursors of the clavicle.

In the Amphibia the dorsally-placed scapula (fig. 27, S) has more dorsally still a cartilaginous plate, the supra-scapula (fig. 27, S.S), which may be calcified. The precoracoid (fig. 27, P.C) and coracoid (C) are quite distinct, the former being in front (cephalad) and overlaid by a dermal bone, the clavicle (Cl). Uniting the ventral ends of the precoracoid and coracoid is the epicoracoid on each side (fig. 27, E.C).

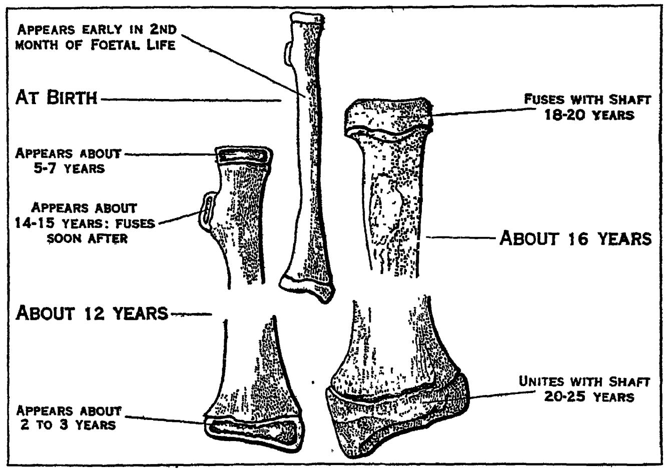
In the Reptilia the same general plan is evident, but in the lizards the ventral ends of the two clavicles are united by a median dagger-like dermal bone, the *interclavicle* (fig. 27, I.C), which lies on a plane superficial to the sternum and epicoracoids.

In birds the scapula has the shape of a sabre blade, and there is a rudimentary acromion process, though this is also indicated in some reptiles. The pre- and epi-coracoids are aborted, but the coracoids are very strong. The clavicles and interclavicle unite into a V-shaped bar which forms the furcula or "merrythought."

In the Mammalia the Monotremata (Ornithorhynchus and Echidna) retain the reptilian arrangement of large coracoids and epicoracoids articulating with the sternum, while the clavicles and interclavicle are also largely developed; the scapula too is more bird-like in shape than mammalian. In the higher mammals the scapula develops a spine and usually an acromial process, and has a triangular outline. As long as the forelimb is used for support, the vertebral border is the shortest of the three, and the long axis of the bone runs from this border to the glenoid cavity; but when the extremity is used for prehension, as in the Primates, or for flight, as in the Chiroptera, the vertebral border elongates and the distance from it to the glenoid cavity decreases so that the long axis is now parallel with that of the body instead of being transverse.

Above the monotremes too the coracoid becomes a mere knob for muscles, and no longer articulates with the sternum. There is thus a sudden transition from the way in which the forepart of the body is propped up on the forelimbs when the coracoid is functional (as in reptiles) to the way in which it is suspended like a suspension bridge between the two scapulae in pronograde mammals, the serratus magnus muscles forming the chains of the bridge (*see* fig. 28).

The clavicle is often entirely suppressed in mammals; this is the case in most of the Ursidae, all the Pinnipedia, Manis among edentates, the Cetacea, Sirenia, all Ungulata and some of the Rodentia. It is complete in all the Primates, Chiroptera, Insectivora (except Potamogale), many of the Rodentia, most Edentata, and all the Marsupialia except Perameles. In the Monotremata it is fused with a well-developed interclavicle, but in other mammals the interclavicle is either suppressed or possibly represented by the sternal epiphysis of the clavicle of the Primates. The pre-coracoid as a distinct structure entirely disappears, though vestiges of it may remain in the cartilaginous parts of the clavicle.

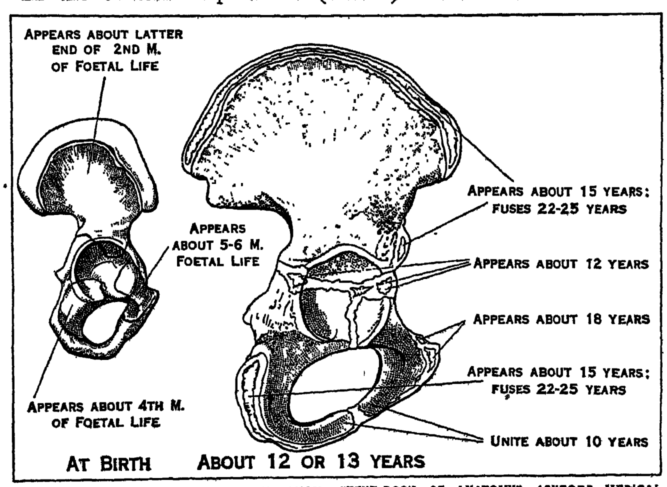


FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 22.—OSSIFICATION OF THE RADIUS

The chief modifications of the *humerus* are the development of the *pectoral ridge*, which is large whenever the pectoral muscles are strong, and is represented in man by the outer lip of the bicipital groove and the *supracondylar foramina*. Epiphyses are found in this, as in other long bones, in amphibians, reptiles and mammals, but not in birds.

In the tailless amphibians (Anura) the *radius* and *ulna* are fused, while in the Urodela and reptiles they are always distinct. In some lizards (Iguana, Sphenodon, etc.) the olecranon epiphysis remains a distinct sesamoid bone just as the patella does, and this is also the case in some bats. In the pronograde mammals the radius is in a position of permanent pronation, and is a much more important bone than the ulna, which is sometimes suppressed, so that little more than the olecranon process remains (*e.g.*, horse, giraffe). In the lower Primates the ulna articulates directly with the cuneiform and (sometimes) pisiform bones, and is not shut off

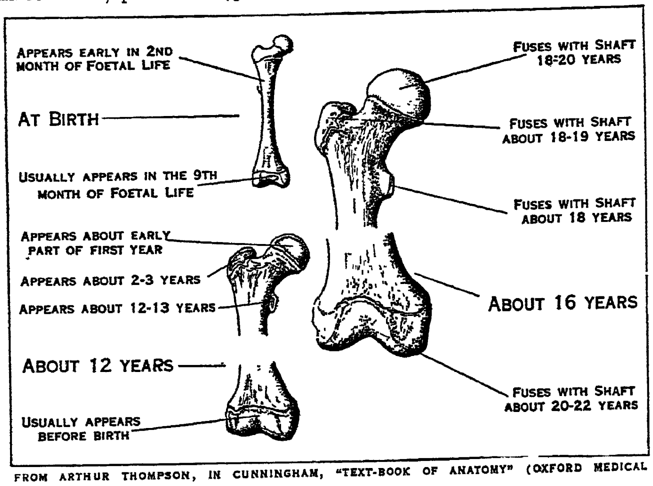


FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 23.—OSSIFICATION OF THE INNOMINATE BONE

from the carpus by a meniscus as in man.

The *carpus* of the higher vertebrates may be reduced from a generalized type by the fusion or suppression of certain of its elements. A perfect generalized type (*see* fig. 29) is not known to exist in any vertebrate. In such a type the bones are arranged in three rows; proximal (5 bones), middle (2 bones), and distal (5



FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 24.—OSSIFICATION OF FEMUR

bones). The primitive reptile sphenodon has all these bones except the radiale marginale.

In many of the urodele amphibians, *e.g.*, the salamander and newt (Molge), the carpus is very generalized; in the tailless forms (Anura), however, it is more specialized. When only four distalia are present it is doubtful whether the fifth is suppressed, or has fused with the fourth.

In the Reptilia the carpus is often very generalized, as in Sphenodon and Chelydra (*see* fig. 30).

In the birds the radiale and ulnare are distinct, but the distal bones are fused with the metacarpus to form a *carpo-metacarpus*. In Mammalia various examples of fusion and suppression occur. In man the radiale, radiale marginale, and centrale radiale fuse to form the scaphoid; the semilunar is the intermedium; the cuneiform the ulnare; and the pisiform the ulnare marginale. The trapezium and trapezoid are distalia I. and II.; the os magnum distale III. fused with the centrale ulnare; while distalia IV. and V. have either fused to form the unciform, or, as some believe, distale V. has been suppressed.

In some mammals the radiale marginale is very large, *e.g.*, mole and elephant, and is regarded as a stage in the evolution of a digit on the radial side of the pollex, hence named the *prepollex*. In the Cape jumping hare (*Pedetes*) this digit is two-jointed and bears a rudimentary nail. Feebler indications of another digit on the ulnar side of the carpus, called the *post-minimus*, are sometimes seen in relation with the pisiform, which is therefore no longer regarded as a sesamoid bone, but, with the radiale marginale, as a stage in the progress from a pentadactylous to a heptadactylous manus. The centrale radiale and radiale marginale persist as distinct bones throughout life in many monkeys.

In the suppression of digits in vertebrates a regular sequence occurs; the pollex is the first to go, then the minimus, index and annularis one after another, so that an animal like the horse, which has only one digit, has lost all except the medius.

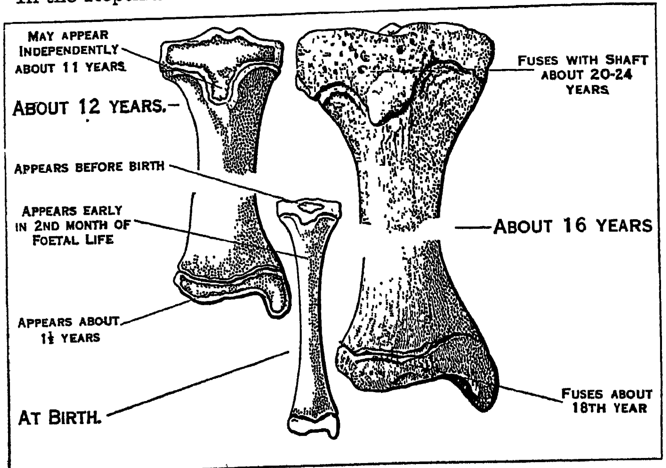
In the mammals the number of the phalanges usually corresponds with that of man, though in the lower vertebrates they are often much more numerous. When the extremity is modified to form a paddle, as in Ichthyosaurus and the Cetacea, the phalanges are often greatly increased in number.

In the elasmobranch fishes the *pelvic girdle* is a repetition of the pectoral though it is not quite so well marked. The acetabulum corresponds to the glenoid cavity, and the part of the girdle dorsal to this is the ilium; the ventral part, uniting with its fellow in the mid-line, is the ischio-pubis, the two elements of which are sometimes separated by a small foramen for the passage of a nerve. When this is the case the anterior (cephalic) part is the pubis, and is in series with the precoracoid, while the ischium (caudad) repeats the coracoid.

In Amphibia the connection between the ilium and sacrum becomes established, and some of the extinct Labyrinthodontia have separate pubic and ischial symphyses, though in existing forms the ischium and pubis are generally fused.

In the Urodela there is usually a bifid cartilage just in front (cephalad) of the pubes, in the mid-line, which is called the *epipubis*.

In the Reptilia the ilium always projects backward towards the

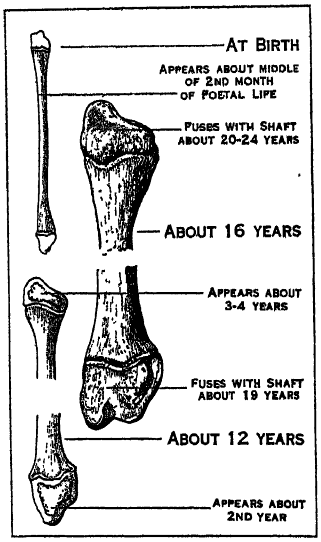


FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 25.—OSSIFICATION OF THE TIBIA

tail; the ischia usually meet in a ventral ischial symphysis, from which a cartilage or bone projects backward to support the anterior lip of the cloacal orifice; this is the *hypoischium*, a structure which is traceable throughout the Vertebrata to man (*see* fig. 31).

The hypoischium and epipubis are parts of a cartilaginous pelvic sternum, the former representing the xiphisternum and the latter the episternum of the shoulder girdle (*see* F. G. Parsons, "Epiphyses of the Pelvis," *J. Anat. and Phys.*, vol. xxxvii., p. 315).



FROM ARTHUR THOMPSON, IN CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 26.—OSSIFICATION OF FIBULA

In birds the ilium extends forward and backward, and is fused with the vertebral column. The ischia and pubes do not form a symphysis except in the struthious birds (ostrich and rhea). The acetabulum is always perforate.

In mammals the ilium projects forward toward the head, and an ischio-pubic symphysis is common, though sometimes it is only pubic as in man. In Echidna among the monotremes the acetabulum is perforate as in birds. In the monotremes and marsupials part of the external oblique muscle is ossified to form the *marsupial bones;* these are sometimes regarded as part of the epipubis, though it is more probable that they are merely adaptive strengthenings of the external oblique to support the traction of the pouch. A *cotyloid bone* (*os acetabuli*) is usually present, at all events in early life, and it often shuts out the pubis from taking any part in the formation of the acetabulum.

The *femur* is comparatively a very stable bone. Sometimes, especially in the odd-toed ungulates (Perissodactyla), the gluteal ridge forms a large third trochanter, while in most mammals, though not in ungulates, there are two sesamoid bones, called fabellae, developed in the gastrocnemius just above the condyles.

The *patella* first appears in the reptiles, though it is not present in all of them. Most of the Lacertilia show it as a small sesamoid structure in the quadriceps extensor tendon. It is present in all birds and mammals, with the exception of some bats. In most marsupials it remains cartilaginous throughout life.

The *tibia* and *fibula* fuse in the Anura and also in some mammals (*e.g.*, rodents). The fibula is often nearly or quite suppressed in birds and mammals, while in birds the tibia fuses with the proximal row of tarsal bones, so that the ankle joint is obliterated and a tibio-tarsus formed. In the marsupials the upper end of the fibula is large and may articulate with the femur in certain positions of the knee, but, as a whole, it reaches its maximum development in the Carnivora in the aquatic suborder of which (Pinnipedia) it is as large as the tibia. It is curious that the only epiphysis which occurs in the long bones of birds is in the head of the tibia of the Gallinaceae.

In the *tarsus* the bones are arranged on the same generalized plan as in the carpus, but the middle row as far as we know only contains one *centrale.*

It is more difficult to trace the fate of these structures in existing vertebrates than it is with the carpal bones. In man the astragalus probably contains the tibiale, tibiale marginale and intermedium. The fibulare and fibulare marginale probably form the calcaneum, though it is unlikely that the epiphysis at the back of that bone represents any integral part of a generalized tarsus. The centrale persists as the navicular, while the three cuneiform represent tarsalia I., II. and III. and the cuboid tarsalia IV. and V., unless V. is suppressed as some believe. Vestiges of a *prehallux* are found in the Cape jumping hare and other rodents, though they are usually more closely connected with the navicular and internal cuneiform than with the bones of the proximal row. The large size of the hallux in man is an adaptation to the erect position.

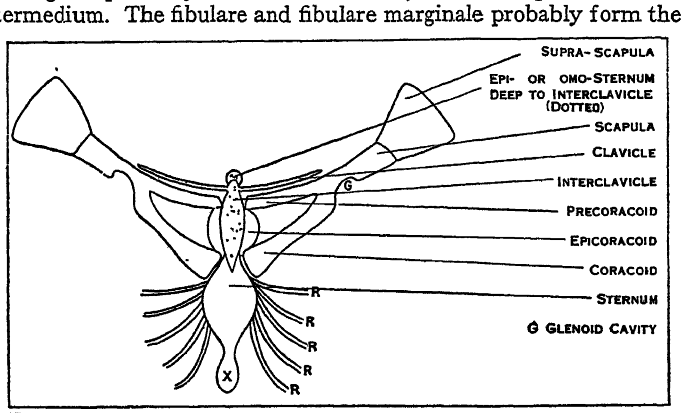


FIG. 27.—DIAGRAM OF A GENERALISED FORM OF SHOULDER GIRDLE

Most of the remarks already made about the metacarpals and phalanges of the hand apply equally to the foot, though there is a greater tendency to reduction of digits in the hind limb than in the fore.

For further details and literature *see* S. H. Reynolds, *The Vertebrate Skeleton* (Cambridge, 1897); W. Flower and H. Gadow, *Osteology of the Mammalia* (London, 1885); R. Wiedersheim, *Comparative Anatomy of Vertebrates,* adapted by W. N. Parker (London, 1907); C. Gegenbaur, *Vergleich Anat. der Wirbeltiere* (Bd. i.) (Leipzig, 1901).

VISCERAL SKELETON

In the lower vertebrates as well as in the embryo of man, a number of cartilaginous or bony arches encircle the mouth and pharynx (anterior part of the food tube), just as hoops encircle a barrel. There is little doubt that, when they first appeared in the history of evolution, all these bars supported gills and bounded gill slits, but in all existing types the first arch has been modified to surround the mouth and to act as both upper and lower jaws, gaining in different animals a more or less complete connection with the cranium or brain-containing part of the skull. The first of these visceral arches, therefore, is known as the oral or jaw arch and, as has been shown, the muscles in connection with it are supplied by the fifth nerve (*see* MUSCULAR SYSTEM; and NERVE: *Cranial*). The second visceral arch is the hyoid and is accompanied by the seventh or facial nerve. The third visceral or first branchial arch of most writers has the ninth or glossopharyngeal for its nerve supply, while the arches behind this are supplied by the vagus or tenth nerve.

In man the maxilla, palate, internal pterygoid plate, malar and tympanic bones as well as the ear ossicles, mandible, hyoid bone and thyroid cartilage are developed in connection with this visceral skeleton. Of these the ear ossicles are described in the article EAR, the thyroid cartilage in that on the RESPIRATORY SYSTEM, while the other bones, with the exception of the hyoid, are treated under SKULL. It therefore only remains to describe here the hyoid bone of man.

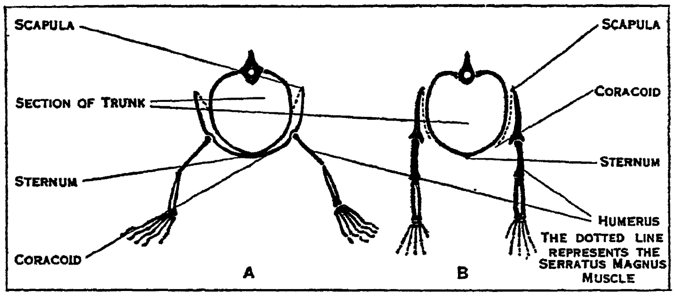

FIG. 28.—TYPES OF SHOULDER GIRDLE, DIAGRAM SHOWING CHANGE OF MECHANISM IN SUPPORTING THE THORAX IN (A) THE REPTILIAN, AND (B) THE MAMMALIAN

Hyoid Bone.—The hyoid bone lies in the upper part of the neck in close connection with the root of the tongue and just above the thyroid cartilage. It consists of a body across the mid-ventral line and a great and small cornu on each side (*see* fig. 32).

The *body* (*basihyal*) is rectangular with its long axis horizontal; behind it is concave from above downward and from side to side. In front it attaches several muscles, but behind it is smooth and is separated from the thyrohyoid membrane by a bursa. From its upper border this membrane runs downward to the thyroid cartilage. The *great cornua* (*thyrohyals*) are attached to each side of the body by cartilage until middle life and afterwards by bony union. They curve upward and backward round the side of the pharynx and are laterally compressed. To their inner surfaces the thyrohyoid membrane is attached, while their knob-like ends are connected with the superior cornua of the thyroid cartilage by the lateral thyrohyoid ligaments.

The *small cornua* (*ceratohyals*) are about a quarter of an inch long. It is only in late life that they become united with the body by bony union, if they ever do so. At their apices they are connected with the tips of the styloid processes by the long stylohyoid ligaments (epihyals).

Embryology.—In the early embryo (*see* MOUTH and SALIVARY GLANDS) the mandibular processes grow forward on each side of the slit-like stomatodaeum or primitive mouth, and at length join one another in the mid-ventral line. From the proximal part of each of these another process, the maxillary, grows forward (ventrad), only more slowly, to blend with the fronto-nasal process. In each of these processes cartilage is formed in the lower vertebrates, which in the case of the mandible (lower jaw) reaches to the mid-ventral line and forms what is known as Meckel's cartilage; but in the maxillary process the stage of chondrification is suppressed in man and other mammals, and the palato-quadrate cartilaginous bar which is so evident in embryo fishes and amphibians is not formed. Thus both the maxillary and the mandibular bars are derivatives of the first visceral arch. In the maxillary process a membrane bone is formed which blends with the sphenoid to form the internal pterygoid plate, while in front (ventrad) of this the upper jaw (maxilla) is developed in membrane by several centres. Of these, one, or perhaps two, form the premaxilla, each of the latter contributing a socket for one of the two incisor teeth. When these premaxillary sutures fail to unite, the deformity known as "cleft

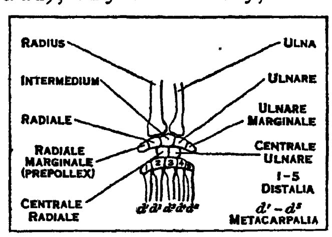

FIG. 29.—DIAGRAM OF A GENERALISED CARPUS

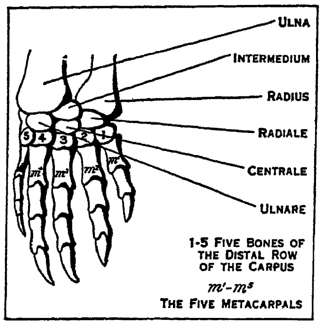
palate" is produced and this may occur either between the lateral incisor and the canine or between the central and lateral incisor teeth.

The *mandibular* or *Meckel's cartilage* is continued up into the tympanum where it joins the proximal end of the cartilage of the second or hyoid arch, and it is from this junction (hyomandibular plate) that, according to H. Gadow, *Anat. Anzeiger,* Bd. 19, p. 396, the malleus and incus bones of the middle ear are developed (*see* EAR). Between the slender process of the malleus and the region of the inferior dental foramen, the cartilage later on disappears and its fibrous sheath forms the *long internal lateral* or *sphenomandibular ligament* (*see* fig. 33, L.I.L.).



FROM GEGENBAUR, "VERGLEICHENDE ANATOMIE DER WIRBELTIERE" (ENGELMANN)

FIG. 30.—DORSAL SURFACE OF RIGHT MANUS OF WATER TORTOISE (CHELYDRA SERPENTINA)

Each half of the lower jaw was long considered to be composed of several distinct skeletal elements, homologous with the elements found in the jaws of lower vertebrates, but it seems evident that in man the process of ossification is slurred over although some of the original elements of the lower vertebrates are repeated as temporary cartilaginous masses, *e.g.,* coronary, condylar and angular. (*See* A. Lowe, "Development of Lower Jaw in Man," *Proc. Anat. Soc.* of the University of Aberdeen, 1905, p. 59.)

At birth the two halves of the mandible are separate as they are throughout life in many mammals (*e.g.,* rodents), but in man they join together about the end of the first year.

It has been stated that within the tympanum the dorsal or proximal ends of the first and second visceral arches unite to form the hyomandibular plate from which the *malleus* and *incus* are derived. The *stapes* is also probably formed from the proximal end of the second or hyoid arch (*see* fig. 33, St.), and just ventral to this the cartilage of the arch fuses with that of the periotic capsule, where it is later on ossified as the *tympanohyal* element of the temporal bone (fig. 33, T.H.). From this point the cartilage becomes free from the skull and runs round the pharynx until it meets its fellow of the opposite side in the mid-ventral line. That part of the cartilage which is nearest the skull remains as the *stylohyal* element (fig. 33, S.H.) and this later on ossifies to form the *styloid process* which fuses with the tympanohyal between twenty and twenty-five. For some distance beyond the stylohyal element the cartilage degenerates into fibrous tissue forming the *stylohyoid ligament;* this represents the *epihyal* element, and occasionally instead of degenerating it ossifies to form an abnormal bone (fig. 33, E.H.). Near the middle line the cartilage persists as the *ceratohyal* element or *lesser cornu of the hyoid bone* (fig. 33, C.H.), while the most ventral part, where it fuses with its fellow of the opposite side as well as with the ventral part of the third arch, is the *basihyal* or *body of the hyoid bone* (fig. 33, B.H.).

The dorsal part of the cartilage of the third arch is wanting, but the lateral part forms the *thyrohyal* or *great cornu of the hyoid bone* (fig. 33, Th.H.), while its ventral part fuses with its fellow of the opposite side as well as with the ventral part of the second arch to form the body of the hyoid bone. The fourth and fifth arches only develop cartilage in their ventro-lateral parts and fuse to form the thyroid cartilage of the larynx (fig. 33, Th.C.) (*see* RESPIRATORY SYSTEM).

Comparative Anatomy.—In the Amphioxus the pharynx is stiffened by chitinous bars which lie between the gill slits, but it is unlikely that these are really homologous with the visceral skeleton of higher forms, though, in serving the same purpose, they are certainly analogous.

Among the Cyclostomata (hags and lampreys) there is an arrangement known as the "branchial basket," which has a more superficial position than the visceral arches of fish and probably corresponds to the extra-branchials of those vertebrates. The oral and hyoid arches are very rudimentary and probably have degenerated in consequence of the suctorial mode of nourishment. In the Elasmobranchii (sharks and rays) the visceral skeleton is entirely cartilaginous. In the more primitive types such as the comb-toothed shark (Notidanus) the oral and hyoid arches are quite distinct. The oral arch consists of the upper jaw, or *palatoquadrate cartilage,* and the lower jaw, or *Meckel's cartilage;* these articulate with one another posteriorly and also with the skull. Behind these and distinct from them is the hyoid arch. Such a type of *suspensorium* or jaw articulation is called *autostylic.* In the rays, on the other hand, the oral arch is connected with the skull by the proximal segment of the hyoid arch, which, since it connects both the hyoid and mandibular (oral) arches with the skull, is called the hyomandibular cartilage. This type of suspensorium is termed *hyostylic.*

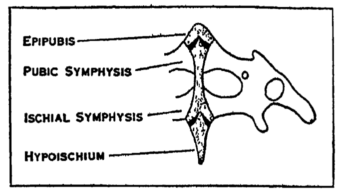


FIG. 31.—PELVIS OF SPHENODON LIZARD

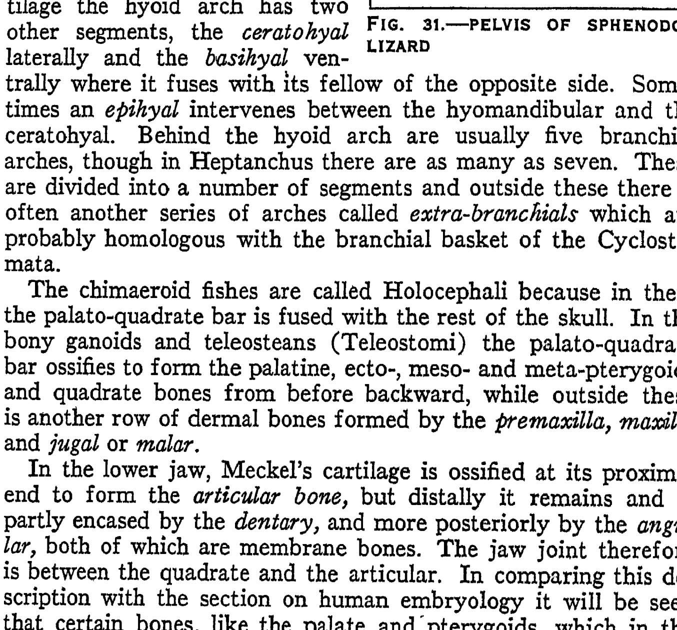
Below the hyomandibular cartilage the hyoid arch has two other segments, the *ceratohyal* laterally and the *basihyal* ventrally where it fuses with its fellow of the opposite side. Sometimes an *epihyal* intervenes between the hyomandibular and the ceratohyal. Behind the hyoid arch are usually five branchial arches, though in Heptanchus there are as many as seven. These are divided into a number of segments and outside these there is often another series of arches called *extra-branchials* which are probably homologous with the branchial basket of the Cyclostomata.

The chimaeroid fishes are called Holocephali because in them the palato-quadrate bar is fused with the rest of the skull. In the bony ganoids and teleosteans (Teleostomi) the palato-quadrate bar ossifies to form the palatine, ecto-, meso- and meta-pterygoids and quadrate bones from before backward, while outside these is another row of dermal bones formed by the *premaxilla, maxilla* and *jugal* or *malar.*

In the lower jaw, Meckel's cartilage is ossified at its proximal end to form the *articular bone,* but distally it remains and is partly encased by the *dentary,* and more posteriorly by the *angular,* both of which are membrane bones. The jaw joint therefore is between the quadrate and the articular. In comparing this description with the section on human embryology it will be seen that certain bones, like the palate and pterygoids, which in the fish are ossifications in cartilage, become in the higher vertebrates



FROM GRAY, "ANATOMY" (LONGMANS GREEN)

FIG. 32.—HYOID BONE, ANTERIOR SURFACE (ENLARGED)

membrane bones, and so it is clear that too great stress must not be laid on the histological history of a bone in determining its morphological significance.

The branchial arches of the Teleostomi closely resemble those of the Elasmobranchii except that they are ossified and that the extra-branchials have disappeared.

In the Dipnoi (mudfish) the suspensorium is autostylic, and either five or six branchial arches are present. In the Amphibia, too, the suspensorium is autostylic, the palato-quadrate bar remains largely cartilaginous, though its posterior part is often ossified to form the quadrate. The membranous *premaxilla, maxilla, palatine, pterygoid, quadratojugal* and *squamosal* bones are

developed in connection with it, though it is interesting to notice that the pterygoid is sometimes partly cartilaginous and the quadrato-jugal is absent in the tailed forms (Urodela). In the lower jaw a *splenial* element has appeared, and in the frog a cartilaginous *mento-meckellian* bone develops close to the symphysis. In the larval stages there are rudiments of four branchial arches behind the hyoid, but in the adult these are reduced in the Anura and their ventral ends are united into a broad basilingual plate.

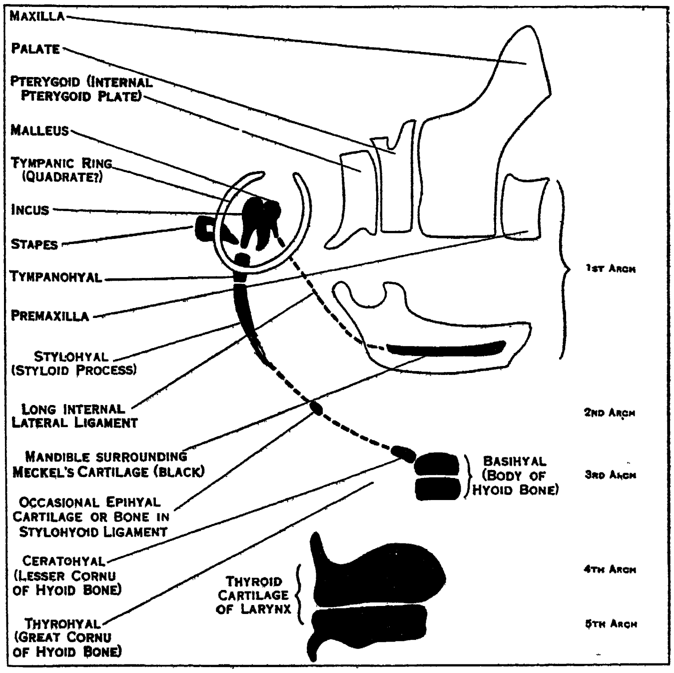


FIG. 33.—DIAGRAM SHOWING FATE OF VISCERAL ARCHES IN MAN AND (WITH MODIFICATIONS) IN OTHER MAMMALS
Membrane bones are white; cartilage and cartilage bones, black; and cartilage which has degenerated into ligaments is dotted

In the Reptilia the site of the palato-quadrate bar is surrounded by the same series of bones that are found in the Amphibia, but in lizards and chelonians a *para-quadrate* bone is found which, according to E. Gaupp, is the precursor of the tympanic ring of mammals. In the crocodiles the maxilla and palate grow inwards to meet one another and so form a hard palate. The mandible has *dentary, splenial, angular, surangular, articular* and *coronoid* ossifications and in some cases a *mento-meckellian* as well. The quadrate bone with which it still articulates is becoming included in the wall of the tympanic cavity, and, according to H. Gadow, it is this bone and not the para-quadrate which will become the tympanic of mammals. The hyoid arch is sometimes suppressed in snakes, but in Sphenodon its continuity with the *columella* or *stapes* can be demonstrated.

The branchial skeleton is reduced with the cessation of branchial respiration and only the ventral parts of two arches can be seen; these unite to form a plate with the hyoid (*basihyobranchial*) and with this the glottis is closely connected. In birds the morphology of the visceral skeleton is on the reptilian plan, and, although the modifications are numerous, they are not of special interest in elucidating the problems of human morphology.

In the Mammalia the *premaxilla, maxilla, palate* and *pterygoid* bones can be seen in connection with the region where the palato-quadrate cartilage lay in the lower Vertebrata (*see* fig. 34). The *premaxilla* bears the incisor teeth, and except in man the suture between it and the maxilla is evident on the face if a young enough animal be looked at. The *maxilla* bears the rest of the teeth and articulates laterally with the *jugal* or *malar,* which in its turn articulates posteriorly with the zygomatic process of the squamosal, so that a zygomatic arch, peculiar to mammals, is formed. Both the maxilla and palate form the hard palate as in crocodiles, but the pterygoid bone fuses with the sphenoid to form the internal pterygoid plate (*see* fig. 34, Pt.). The *mandible* no longer articulates with the *quadrate* but forms a new articulation, by means of the condyle, with the *glenoid cavity of the squamosal,* and many modern morphologists hold that the quadrate has become the *tympanic bone.* In many mammals (*e.g.,* Carnivora) this bone swells out to form the *bulla tympani.* The derivation of the auditory ossicles has been discussed in the section on embryology as well as in the article EAR. The presence of a chain of ossicles is peculiar to the Mammalia.

In many of the lower mammals (*e.g.,* Ungulata and Carnivora) the hyoid arch is much more completely ossified than it is in man, *tympano-, stylo-, epi-, cerato-* and *basihyal* elements all being bony (*see* fig. 34). It is of interest to notice that in the hares and rabbits the body of the hyoid has occasionally been found in two pieces, indicating its derivation from the second and third visceral arches. The fourth and fifth arches, which form the thyroid cartilage in mammals, are considered in the article RESPIRATORY SYSTEM.

THE INVERTEBRATE SKELETON

The materials of the skeleton are very variable; it may, as in the case of the Vertebrate notochord, consist of living cells which have acquired rigidity by the accumulation of water under pressure in vacuoles and their cytoplasm, that is, by turgones. More usually it consists of non-living materials laid down by cells either within their cytoplasm or outside their surface membrane.

In the case of an exoskeleton, the process of skeleton formation begins with the formation on the outer surface of the animal of a thin layer, usually of an organic substance which forms a cuticle, a structure exactly similar theoretically to a cell wall, but forming a continuous sheet over an epithelium, and resulting from the activities of many cells. This cuticle may remain as a thin layer, serving to resist the mechanical wear to which the outer surface of all animals is subjected, added to only sufficiently to replace loss by abrasion. But in many cases the cuticle is so much thickened that it becomes inflexible, and gives a permanent form to the part of the animal which it surrounds. It may serve, even when thin, to cement a sedentary animal to its base. The cuticle usually consists of a substance which is a protein, though in Tunicates the test, which is, in effect, a much modified cuticle, is of tunicin, a cellulose. The scleroproteins which compose cuticles vary much in their nature, chitin, which is chemically, perhaps, as closely allied to cellulose as to the proteins, is the most widespread and important. The organic basis of the cuticle may serve as a matrix in which mineral salts may be laid down, so as to harden and still further stiffen the exoskeleton. These salts are usually mixtures of phosphates of calcium and magnesium, or calcium carbonate, in the crystalline form of arragonite or calcite. An exoskeleton of this kind is found in certain Protozoa, in Hydomedusae, Gorgonians, and Zoantharia amongst the Coelenterates, in Polyzoa, Brachiopoda, Mollusca, and reaches its highest development amongst the Arthropoda.

In Coelenterates, the exoskeleton forms a mere support to the animal, and is, except in certain Gorgonians, inflexible and continuous. In Brachiopoda and Mollusca, it forms a shell to which muscles are attached, so that movements of the animal with respect to the shell and of the different parts of the skeleton can be brought about. The shells of Brachiopods and Molluscs are often beautiful mechanical devices provided with interlocking teeth which ensure accurate closure, and presenting, in their shape and special structure, a very great strength for their weight.

The exoskeleton of the Arthropods is far more complex, although actually continuous, not only over the whole external surface, but into those anterior and posterior portions of the gut which are lined by ectoderm. It is functionally divided into a series of segments or somites consisting of a ring of hard chitin, often more or less calcified, which are connected together by areas of thinner and flexible chitin, so that they may move on one another. Each segment may bear a pair of appendages, each of which is covered by a chitinous cuticle divided into segments movable on one another, though, like those of the body, connected by flexible rings.

The individual sclerites, the hard areas of cuticle, may become hinged to one another by special processes, and are, in all cases, moved by muscles which lie inside them. In such cases as the claw of a lobster, special processes arising from the exoskeleton push their way into the body of the animal in order to give favourable points of attachment to muscles.

The existence of this exoskeleton, which cannot, when once made, increase in area, and whose existence is necessary for the functioning of the animal, renders continuous growth impossible, and has led to the strange process of ecdysis. After a certain period the cuticle cracks along definite lines and the animal crawls out of it, leaving behind the complete structure, retaining the whole of the external surface and even part of the lining of the gut. The animal so freed of restraint very rapidly enlarges and then a new cuticle is formed and hardens to form a new skeleton. Details of the structure of these skeletons must be sought in the separate articles.

An endoskeleton exists in Protozoa, sponges, some Alcyonaria, Brachiopoda, Echinodermata, Chordata and Cephalopod molluscs The protozoan endoskeleton may be protein in nature, or it may consist of calcium and magnesium carbonates, silica, or even in one case, of strontium sulphate. It is necessarily intracellular, being completely covered by the cytoplasm of the single cell of which the animal consists.

The sponge skeleton appears always to begin as a series of small rods of some organic material on which spicules of calcium carbonate or of silica are formed. These spicules, in some cases, at any rate, are formed within the bodies of cells, or of fused groups of cells. They arise as isolated structures, and may retain their independence throughout the life of the animal, or they may fuse to form more elaborate structures. Though usually small, they may become gigantic, several feet in length in the case of the anchoring spicules of the glass rope sponge and its allies.

In addition to the spicules, many sponges possess a skeleton of a protein substance, spongin, which extends throughout their substance but is usually regarded as an exoskeleton. The endoskeleton of the Alcyonaria consists of spicules which are of intracellular formation that may remain isolated or may be fused into such a substance as precious coral. The Echinoderm skeleton is of mesodermal origin, and is unique in that each of the elements of which it is composed consists of a single crystal of calcite. It is very highly developed in most forms, the individual elements articulating with one another, often by elaborate joints, and being movable by a highly-developed musculature. (D. M. S. W.)

SKELTON, JOHN (*c.* 1460–1529), English poet, is variously asserted to have belonged to a Cumberland family and to have been a native of Diss in Norfolk. He is said to have been educated at Oxford. He certainly studied at Cambridge, and he is probably the "one Scheklton" mentioned by William Cole (ms. *Athen. Cantabr.*) as taking his M.A. degree in 1484. In 1490 Caxton writes of him, in the preface to *The Boke of Eneydos compyled by Vyrgyle*, in terms which prove that he had already won a reputation as a scholar. "But I pray mayster John Skelton," he says, "late created poete laureate in the unyversite of Oxenforde, to oversee and correct this sayd book . . . for him I know for suffycyent to expowne and englysshe every dyffyculte that is therein. For he hath late translated the epystlys of Tulle, and the boke of dyodorus siculus, and diverse other works . . . in polysshed and ornate termes craftely . . . I suppose he hath drunken of Elycons well." The laureateship referred to was a degree in rhetoric. Skelton received in 1493 the same honour at Cambridge. Skelton found a patron in the pious and learned countess of Richmond, Henry VII.'s mother, for whom he wrote *Of Mannes Lyfe the Peregrynacioun*, a translation, now lost, of Guillaume de Deguilleville's *Pèlerinage de la vie humaine*. An elegy "Of the death of the noble prince Kynge Edwarde the forth," included in some of the editions of the *Mirror for Magistrates*, and another (1489) on the death of Henry Percy, fourth earl of Northumberland, are among his earliest poems. In the last decade of the century he was appointed tutor to Prince Henry (afterwards Henry VIII.). He wrote for his pupil a lost *Speculum principis*, and Erasmus, in dedicating an ode to the prince in 1500, speaks of Skelton as "unum Britannicarum literarum lumen ac decus." In 1498 he was successively ordained sub-deacon, deacon and priest. He seems to have been imprisoned in 1502, but no reason is known for his disgrace. Two years later he retired from regular attendance at court to become rector of Diss, a benefice which he retained nominally till his death. Skelton frequently signed himself "regius orator" and poet-laureate, but there is no record of any emoluments paid in connection with these dignities. His parishioners thought him, says Anthony à Wood, more fit for the stage than for the pulpit. He was secretly married to a woman who lived in his house, and he had earned the hatred of the Dominican monks by his fierce

satire. He was censured by Richard Nix, bishop of the diocese, and appears to have been temporarily suspended. After his death a collection of farcical tales, no doubt chiefly, if not entirely, apocryphal, gathered round his name—*The Merie Tales of Skelton.* During the rest of the century he figured in the popular imagination as an incorrigible practical joker. His sarcastic wit made him some enemies, among them Sir Christopher Garnesche or Garneys, Alexander Barclay, William Lilly and the French scholar, Robert Gaguin (*c.* 1425–1502). Earlier in his career he had found a friend and patron in Cardinal Wolsey, and the dedication to the cardinal of his *Replycacion* is couched in the most flattering terms. But in 1522, when Wolsey in his capacity of legate dissolved convocation at St. Paul's, Skelton put in circulation the couplet:

> Gentle Paul, laie doune thy sweard
> For Peter of Westminster hath shaven thy beard.

In *Colyn Cloute* he incidentally attacked Wolsey in a general satire on the clergy, but *Speke, Parrot* and *Why come ye nat to Courte?* are direct and fierce invectives against the cardinal who is said to have more than once imprisoned the author. To avoid another arrest Skelton took sanctuary in Westminster Abbey. He was kindly received by the abbot, John Islip, who continued to protect him until his death on June 21, 1529.

In his *Garlande of Laurell* Skelton gives a long list of his works, only a few of which are extant. The garland in question was worked for him in silks, gold and pearls by the ladies of the countess of Surrey at Sheriff Hutton Castle, where he was the guest of the duke of Norfolk. The composition includes complimentary verses to the various ladies concerned, and a good deal of information about himself. But it is as a satirist that Skelton merits attention. *The Bowge of Court* is directed against the vices and dangers of court life. He had already in his *Boke of the Thre Foles* drawn on Alexander Barclay's version of the *Narrenschiff* of Sebastian Brant, and this more elaborate and imaginative poem belongs to the same class. Skelton, falling into a dream at Harwich, sees a stately ship in the harbour called the *Bowge of Court,* the owner of which is the Dame Saunce Pere. Her merchandise is Favour; the helmsman Fortune; and the poet, who figures as Drede (modesty), finds on board Favell (the flatterer), Suspect, Harvy Hafter (the clever thief), Dysdayne, Ryotte, Dyssymuler and Subtylte, who all explain themselves in turn, until at last Drede, who finds they are secretly his enemies, is about to save his life by jumping overboard, when he wakes. Both of these poems are written in the seven-lined Chaucerian stanza, but it is in an irregular metre of his own that his most characteristic work was accomplished. *The Boke of Phyllyp Sparowe,* the lament of Jane Scroop, a schoolgirl in the Benedictine convent of Carowe near Norwich, for her dead bird, was no doubt inspired by Catullus. It is a poem of some 1,400 lines with many digressions. We learn what a wide reading Jane had in the romances of Charlemagne, of the Round Table, The Four Sons of Aymon and the Trojan cycle. Skelton finds space to give his opinion of Chaucer, Gower and Lydgate. He seems fully to have realized Chaucer's value as a master of the English language. Gower's matter was, he said, "worth gold," but his English antiquated. The verse in which the poem is written, called from its inventor "Skeltonical," is here turned entirely to whimsical use. The lines are usually six-syllabled, but vary in length, and rhyme in groups of two, three, four and even more. It is not far removed from the old alliterative English verse, and well fitted to be chanted by the minstrels who had sung the old ballads. For its comic admixture of Latin Skelton had abundant example in French and Low Latin macaronic verse. He makes frequent use of Latin and French words to carry out his exacting system of frequently recurring rhymes. This breathless, voluble measure was in Skelton's energetic hands an admirable vehicle for invective, but it easily degenerated into doggerel. By the end of the 16th century he was a "rude rayling rimer" (Puttenham, *Arte of English Poesie*), and at the hands of Pope[1] and Warton he fared even worse. His own criticism is a just one:—

> For though my ryme be ragged,
> Tattered and jagged,
> Rudely rayne beaten,
> Rusty and moughte eaten,
> It hath in it some pyth.

Colyn Cloute represents the average country man who gives his opinions on the state of the church. There is no more scathing indictment of the sins of the clergy before the Reformation. He exposes their greed, their ignorance, the ostentation of the bishops and the common practice of simony, but takes care to explain that he writes in defence of, not against, the church.

The charge of coarseness regularly brought against Skelton is based chiefly on *The Tunnynge of Elynoure Rummynge,* a realistic description in the same metre of the drunken women who gathered at a well-known ale-house kept by Elynour Rummynge at Leatherhead, not far from the royal palace of Nonsuch. "Skelton Laureate against the Scottes" is a fierce song of triumph celebrating the victory of Flodden. "Jemmy is ded And closed in led, That was theyr owne Kynge," says the poem; but there was an earlier version written before the news of James IV.'s death had reached London. This, which is the earliest singly printed ballad in the language, was entitled *A Ballade of the Scottysshe Kynge,* and was rescued in 1878 from the wooden covers of a copy of *Huon de Bordeaux.* "Howe the douty Duke of Albany, lyke a cowarde knight" deals with the campaign of 1523, and contains a panegyric of Henry VIII. To this is attached an *envoi* to Wolsey, but it must surely have been misplaced, for both the satires on the cardinal are of earlier date.

Skelton also wrote three plays, only one of which survives. *Magnificence* is one of the best examples of the morality play. It deals with the same topic as his satires, the evils of ambition; its moral, "how suddenly worldly wealth doth decay," being a favourite one with him. Thomas Warton in his *History of English Poetry* described another piece *Nigramansir,* printed by Wynkyn de Worde in 1504, and dealing with simony and the love of money in the church; but no copy is known to exist, and some suspicion has been cast on Warton's statement.

Illustration of the hold Skelton had on the public imagination is supplied from the stage. A play (1600) called *Scogan and Skelton,* by Richard Hathway and William Rankins, is mentioned by Henslowe. In Anthony Munday's *Downfall of Robert, earl of Huntingdon,* Skelton acts the part of Friar Tuck, and Ben Jonson in his masque, *The Fortunate Isles,* introduced "Skogan and Skelton in like habits as they lived."

Very few of Skelton's productions are dated, and their titles are here necessarily abbreviated. Wynkyn de Worde printed the *Bowge of Court* twice. *Divers Balettys and dyties solacious devysed by Master Skelton Laureat,* and *Skelton Laureate agaynste a comely Coystroune* . . . have no date or printer's name, but are evidently from the press of Richard Pynson, who also printed *Replycacion against certain yong scolers,* dedicated to Wolsey. *The Garlande or Chapelet of Laurell* was printed by Richard Faukes (1523); *Magnificence, A goodly interlude,* . . . probably by John Rastell about 1533, reprinted (1821) for the Roxburghe Club. *Hereafter foloweth the Boke of Phyllyp Sparowe* was printed by Richard Kele (1550?), Robert Toy, Antony Kitson (1560?), Abraham Veale (1570?), John Walley, John Wyght (1560?). *Hereafter foloweth certaine bokes compyled by mayster Skelton* . . . including "Speke, Parrot," "Ware the Hawke," "Elynoure Rummynge" and others, was printed by Richard Lant (1550?), John King and Thomas March (1565?), and John Day (1560). *Hereafter foloweth a litle boke called Colyn Cloute* and *Hereafter . . . why come ye nat to Courte?* were printed by Richard Kele (1550?) and in numerous subsequent editions. *Pithy, plesaunt and profitable workes of maister Skelton, Poete Laureate. Nowe collected and newly published* was printed in 1568, and reprinted in 1736. A scarce reprint of *Elinour Rummin* by Samuel Rand appeared in 1624.

See *The Poetical Works of John Skelton; with Notes and some account of the author and his writings,* by the Rev. Alexander Dyce (2 vols., 1843). A selection of his works was edited by W. H. Williams (London, 1902). *See* also *Zur Charakteristik John Skeltons* by Dr. Arthur Koelbing (Stuttgart, 1904); F. Brie, "Skelton Studien" in *Englische Studien,* vol. 38 (Heilbronn, 1877, etc.); A. Rey, *Skelton's Satirical Poems* . . . (Berne, 1899); A. Thümmel, *Studien über John Skelton* (Leipzig-Reudnitz, 1905); G. Saintsbury, *Hist. of Eng. Prosody* (3 vols. 1906–10); and A. Kölbing in the *Cambridge History of English Literature* (vol. iii., 1909).

SKELTON AND BROTTON, an urban district in the North Riding of Yorkshire, England, 17 m. E. by S. of Middles-

[1]Pope said: "Skelton's poems are all low and bad, there is nothing in them that is worth reading" (Spence, *Anecdotes,* p. 87).

brough by the L.N.E. railway, with stations at Brotton and North Skelton. Pop. (1931) 13,654. Altitude 400 feet. This is one of the largest townships in the Cleveland ironstone district, and its industrial population is wholly employed in the quarries. It is near the Skelton Beck which flows to the sea at Saltburn, 3 m. away. The Cleveland hills rise sharply southward to elevations sometimes exceeding 1,000 feet. The modern Skelton castle incorporates part of a 12th century stronghold. Ruins remain of an ancient church, and a fine Norman font is preserved.

SKENE, WILLIAM FORBES (1809–1892), Scottish historian and antiquary, was the second son of Sir Walter Scott's friend, James Skene (1775–1864), of Rubislaw, near Aberdeen. In 1832 he became a writer to the signet, and shortly afterwards obtained an official appointment in the bill department of the Court of Session, which he held until 1865. His early interest in the history and antiquities of the Scottish Highlands bore its first fruit in 1837, when he published *The Highlanders of Scotland, their Origin, History and Antiquities.* His chief work, however, is his *Celtic Scotland, a History of Ancient Alban* (3 vols., Edinburgh, 1876–1880), perhaps the most important contribution to Scottish history written during the 19th century. In 1881 he became historiographer royal for Scotland. He died in Edinburgh on Aug. 29, 1892.

The most important of Skene's other works are: editions of John of Fordun's *Chronica gentis Scotorum* (Edinburgh, 1871–1872); of the *Four Ancient Books of Wales* (Edinburgh, 1868); of the *Chronicles of the Picts and Scots* (Edinburgh, 1867); and of Adamuan's *Vita S. Columbae* (Edinburgh, 1874); an *Essay on the Coronation Stone of Scone* (Edinburgh, 1869); and *Memorials of the Family of Skene of Skene* (Aberdeen, 1887).

SKI (shē or skē), the wooden snow-shoe used in Scandinavia and neighbouring countries for travel over the snow. (Icel. *scidh,* snow-shoe, properly "piece of wood.") Implements for this purpose were used by many nations of antiquity. Xenophon (*Anab.* iv. 5) describes the shoes or pattens of skins with which the horses of the Armenians were shod, to prevent them from sinking into the snow, and Procopius made mention of the ancient Lapps, known in Scandinavia as "Skrid-Finnen," or sliders. Snow-shoes have always been used by the Mongols of north-western Asia. From the evidence of the old Norse sagas they must have been general in Scandinavia long before the Christian era. Ulf (or Ullar), the god of winter, is always spoken of as walking upon ski, the curved toes of which gave rise to the legend that they were really ships upon which the god was wafted over hill and dale. Northern poets of the 9th century refer to ships as "the ski of the sea." Ski have been used time out of mind by Lapps, Finns and Scandinavians for hunting and journeying across the frozen country. The first ski of which there is any record were elongated, curved frames covered with leather. Those of the Skrid-Finnen of the 16th century were leather shoes, pointed at the toe, about 3ft. long, into which, a few inches from the rear end, the feet were thrust up to the ankles. On a rune-stone standing at a cross-road not very far from Upsala there is a picture of a ski-runner with arm-bow; this is probably the oldest picture of a skier. It dates from the 11th century. Modern ski are not, like the North American snow-shoe, made of broad frames covered with a thong web, but long, narrow, nearly flat pieces of ash, oak, beech, birch, spruce or hickory, pointed, turned up about a foot at the toe. Their length is usually the distance the wearer can reach upwards with his hand, that for the average man being about 7ft. 6in., although some advocate less length. Their width at the broadest part is about 5in., and their greatest thickness (just under the foot) about 1¼in., tapering towards both ends. The under surface is usually perfectly smooth, although some ski have slight grooves to prevent the snow caking. They are kept in condition by oiling and waxing; paraffin wax is used to produce a very highly polished surface, which greatly increases the speed of the runner. Long strips of sealskin are sometimes attached to the under side of the ski, to prevent back-sliding, and assist the climber to make a more direct ascent. Without the use of skins one must climb in a zigzag course or place the ski alternately, in a herring-bone pattern.

The ski are fitted to the feet by an arrangement of straps, called the *binding.* There are a very large number of bindings of various types, the commonest among novice runners is the *huitfeld,* and the most popular with more experienced skiers the B.B. This is a metal binding without any straps, relying entirely on a hook and eye arrangement at the toe of the boot. The boots are stoutly made of deer hide and for use with the heel-strap bindings have specially shaped heels with a groove which holds the strap in place. On level ground the ski glide evenly over the snow without being lifted from it, the heels being raised with each forward movement: long gliding steps can be taken without undue fatigue, the runner having a stick about 4ft. or 5ft. long in each hand, to assist progression; these sticks have a spiked end, about 7in. above which a metal disk is fixed to prevent the stick sinking into the snow. Downhill progression attains great velocity; the skier places one foot slightly in advance of the other and runs in a somewhat crouched position with the feet close together and body leaning forward. A single staff was formerly used as a brake in coasting downhill, but the popularity of two sticks used chiefly for assistance in uphill work, but also for balance on the descent, is now almost universal.

Ski-ing as a sport began about 1860 in the Norwegian district of Telemark and rapidly spread over all the Scandinavian peninsula. The climax of the racing season is the great international ski tournament held annually in February at Holmenkollen, 6m. from Oslo. This famous contest was first held in the year 1892, Swedish skiers being present: a few weeks later the first international ski races were organized in Stockholm. The "Norwegian Derby" is divided into two parts, the first devoted to jumping contests, the other to long-distance racing. The take-off for the jumping contests is built into the side of a hill, and each competitor must jump three times. No staff is allowed and no jump is counted if the jumper falls in alighting. The distances covered are extraordinary, 58·50 metres being the record. The jumper, starting a distance up the hill, descends at top speed, stoops as he nears the take-off, and launches himself into the air with all his force. He maintains an erect position until he reaches the ground, alighting with bended knees, on both feet, one a little in advance of the other and "giving" with his legs to overcome the force of the fall and to preserve his balance. Another feature is double jumping, performed by two persons hand in hand. The highest prize is the King's Cup. The principal distance race is over a difficult course of about 20 miles. The record for 25km. (15½ miles) is 2hr., 7 minutes. A Lapp once covered 220km. (about 138 miles) in 21hr. 22 min., the country being level. Ski-ing is very popular in Norway with both men and women; in fact it may be called the national sport of Norway. The sport has been introduced into other countries where the winter is severe, and has become very popular in Switzerland and the United States, especially in Minnesota and the Rocky Mountain country. The mails between Chile and the Argentine republic are carried in winter by relays of Norwegian ski-runners, about 300 being employed. The ski worn by them are usually shod with horn. Ski cannot be used with advantage during a thaw or where the snow is less than 6in. deep. On this account, and because of their general unwieldiness, they are less convenient in thick forests than the Indian snow-shoe, though faster in the open country.

Great Britain.—In Great Britain the use of the ski has been encouraged by the activities of several ski clubs. The Ski Club of Great Britain, founded in 1903, was for years recognized as the governing body for the sport. In 1908 the Alpine Ski Club was started, and membership confined to those who qualified for election by tours on ski in the High Alps. This club was founded entirely for the mountaineer who climbed on ski. In 1912 the British Ski Association was formed; this body had aims very similar to those of the Ski Club of Great Britain and in 1924 the two clubs amalgamated and jointly became known as the Ski Club of Great Britain, and as such is the governing body for the sport in the British Isles. According to Arnold Lunn in a "History of Ski-ing" in the Year-Book of the Ski Club of Great Britain (1925), ski were used in Cumberland in the 19th century and probably in Devonshire 300 years ago.

Germany.—Ski-ing in Germany was almost unheard of until

Wilhelm Paulke was given a pair of ski for a present, about the year 1883. Paulke afterwards became the pioneer of ski-ing in his country, and together with two Norwegians who ascended The Brocken in 1884 was responsible for the foundation of the sport in Germany. In 1890 the first German ski club was formed; it was called the "Ski Club Munich." The first ski competitions were held in Germany in 1896.

Switzerland.—In 1883 the monks of St. Bernard were presented by a traveller with a pair of ski, and six years later the friars had become skiers indeed, for the monastery owned about a dozen pairs of ski, and races were held. This seems the earliest record of ski-ing in Switzerland, but the sport seems to have really gained ground after the year 1889 when a Norwegian, O. Kjelsberg, made some ascents on ski. The first Swiss ski club was formed in the year 1893 and was called "The Ski Club Glarus" —and in 1902 the first ski races were held at Berne. This was not a championship meeting, however, and it was not until the year 1905 that the first Swiss championship meeting was held at Glarus.

France.—Ski-ing in France dates from the great exhibition of 1878 in Paris. Swedish ski were a feature of one of the exhibits, and were afterwards the property of M. Duhamel, who attempted to use them without any conspicuous success. In the year 1893, some ski-runners appeared in the Bois de Boulogne; their efforts were not very enlightening and the French people were derisive. However, three years later the first French ski club was formed with headquarters at Grenoble, and was called the Ski Club des Alpes,-and French ski-ing really became popular at Chamonix in 1898.

Canada.—Canada's natural resources made it an ideal country for ski-ing, and in the Laurentians it has become one of the most popular winter pastimes. The early pioneers were members of the universities who, fresh from a tour in Europe, had seen ski-running and jumping at Davos; and students at McGill university were soon practising on the narrow Scandinavian type of racing ski. The famous Revelstoke hill is the world's fastest "jumping hill"; it was on this that Nels Nelson jumped 202ft.

Australia and New Zealand.—The largest ski resort in Australia is Mt. Kosciusko in New South Wales; here there is an excellent hotel well equipped for the ski enthusiasts who foregather for the meetings organized by the Mt. Kosciusko Ski Club. In New Zealand the popularity of ski-ing as a sport has yet to become established, although the mobile value of the ski has been demonstrated in no uncertain way on the Tasman Glacier.

Military Ski-ing.—Ski have been used for military purposes by the northern peoples for several centuries, and of late years other nations which have mountainous regions of snow have turned their attention to this most useful mode of winter marching. The army of Sweden (under Gustavus Adolphus and his successors one of the foremost in Europe) employed infantry provided with ski in its military operations. In Norway special units so provided were organized in 1710. Since 1902 the Alpine infantry of France and Italy have taken up the question. In Briançon, attached to the 159th regiment of French infantry, is an *école militaire de ski* (established 1903) which trains the *Chasseurs Alpins* of the first line, and also the regional troops which are intended to take part in the defence of the south-eastern frontier of France. These regiments as a rule furnish one officer, one non-commissioned officer, and a few soldiers each to every course of instruction, which lasts two months. At the end of the first month the *skieur* is expected in full marching order to cover 60km. (37½ miles) of Alpine territory in the day. The ski are put to a variety of ingenious uses; to form a stretcher-sledge for wounded men; and if rapidity of movement is desired, a horse or pony pulls the *skieur* along by means of long reins attached to the horse's girth. Even camps in the mountains are improvised. The *skieur* is thickly clothed and muffled, and his eyes are protected against snow-blindness by blue or black spectacles. Some of the performances of soldiers on ski have been notable. Capt. Bernard, chief of the *école* of Briançon, ascended the *cols* of Arsiné (2,400 metres) and of the Cauterel (2,080 metres) in 16hr. with a party of 25 men. In Russia some troops from Finland in full marching order made a long hunting march in Carelia. In 29 days they covered 860 kilometres. In Switzerland a *skieur* took less than 1½hr. to cover 25km., including altitudes of 1,547 metres. In order to witness this competition, which took place in Glarus, the soldiers from the St. Gotthard garrison made a march of 48km. including the ascent of the Klausenpass (2,000 metres). A Norwegian soldier named Holte covered with one leap a distance of 21·20 metres, and his companion Heyderdahl later achieved 24 metres.

In Italy each company of *Alpini* has an annual credit for the provision of ski. Their duties in war time are almost the same as those of mounted infantry—exploration and communication, and the seizure of advanced positions. In the seven months of snow on these frontiers the garrisons of the lonely posts cannot go out save on ski or snow-shoes, as to the respective merits of which military opinion is divided.

The United States.—Ski-ing has become the major winter outdoor recreation along the snow belt of Canada and the United States. Though the best all around development of the sport is in Canada, since about 1920 the United States, especially northern New England, has shown a phenomenal increase in clubs, tournaments and the actual numbers of people who are using ski. One merchant in a New England town of 8,000 population sold 1,200 pair of ski in one season. In practically all the snow sections of the United States the tendency of ski-ing towards becoming an outstanding national sport is evident.

Popular interest in ski-ing takes the form of tours, or "hikes" as they are termed in the United States. These tours consist of club or group ski trips over charted or uncharted trails ranging from trips over hills and meadows to more adventurous expeditions up mountains and over mountain ranges. Ski clubs maintain cabins and huts on trails marked out over the White mountains, Green mountains and the Rockies.

Ski proficiency tests are maintained by which a high standard of ski proficiency on tours and in contests may be secured. A few clubs engage the services of ski instructors. One of the outstanding clubs in the United States for the promotion of general ski training for all around ability in touring is the Lake Placid Club, in New York.

The United States have helped to make ski-ing history in the development of the most sensational type of ski sport—ski jumping. Torjus Hemmestvelt, one of the first of the world's record-breaking jumpers, came to Red Wing, Minn., in 1893 and jumped 103 ft. on this pioneer United States hill. This established a world's record. Since then the record-jumping distances have advanced steadily. In the United States, due to the size of the country, two major competitions are held, the National Tournament fostered by the U.S. Amateur Ski Association, and the Eastern Tournament, conducted under the auspices of the Eastern United States Ski Association. In addition to these competitions a great number of lesser but important tournaments that attract thousands of people are conducted. Each snow season produces a great number of State, interstate, collegiate, interscholastic and inter-club ski-jumping competitions. Listed among the world's greatest jumping hills, where jumps of over 150 ft. can be made, is Brattleboro, Vt., with a record of 190 feet. There are other hills in development where jumps of over 150 ft. will be made.

Cross-country ski racing has been conducted as a separate race. Its distances have lacked standardization. They have ranged from 5 to 25 miles. The ski clubs are tending to follow the plan of the Continental clubs and have the cross-country race combined with the ski jumping, the highest point winner in both events winning the competition. This plan will give the cross-country race a greater interest and importance, which it deserves.

Ski racing down a long or short hill, either in what is called

the down-hill or the shalom, has only recently been taken up in the United States. The lack of accessible mountains near most of the ski clubs or tournament grounds makes the Alpine style of long down-hill race almost impossible. But the shorter shalom race down a hill around artificial obstacles is rapidly becoming a feature of the competitions. The U.S. clubs look to the shalom race to develop a greater number of experts in all around ski-ing.

The United States and Canada affiliate their amateur ski interests through a close association of the national organizations, the Canadian Amateur Ski Association, the National Ski Association of America and the Eastern United States Ski Association. These, in turn, are affiliated with the British Ski Association and exchange courtesies, information and competitive co-operation.

See *The Ski Sport,* year-book of the National Ski Association of America, Inc.; Elon Jessup, *Snow and Ice Sports* (1923).

(F. K. B.)

SKIBBEREEN, a market town of Co. Cork, Ireland, on the river Ilen about 3 m. from its estuary, 53¾ m. S.W. of Cork by the Great Southern railway. Pop. (1926) 2,620. The river is navigable for small vessels to Skibbereen itself, and for larger ones to Old Court on the estuary; and the town is a flourishing fishing-station. Trade is in corn and other agricultural produce. The district suffered much in the famine of 1847, and many were buried in the graveyard adjoining the ruined Cistercian cell of Abbeystrowry, a mile west of the town. The Ilen offers fishing, late in the season, for brown and sea trout.

SKIEN, a seaport of southern Norway, in Bratsberg *amt* (county), on the river Skien, 6 m. above Frier Fjord. Pop. (1927) 15,950. It was mostly rebuilt after a fire in 1886. Here Henrik Ibsen, the dramatist, was born in 1828. In 1892 a canal ascending 189 ft. by means of 17 locks was made between lakes Bandak and Nord, giving access to the Telemark district by way of Dalen. The distance between the lakes is 40 m., and several fine falls, as the Ulefos, Eidsfos, and Vrangfos, are passed. The engineering is noteworthy. There are numerous saw-mills, planing, cotton-spinning and flour-mills, factories for wood-pulp and domestic commodities. The exports are ice, timber (including telegraph poles), wood-pulp and iron ore, and the imports coal and china-clay. The town (the ancient *Skida*) dates from the 14th century.

SKILLUH, the name given by the Arabized Moors to the Berber peoples of southern Morocco. They occupy chiefly the province of Sus. The name is said to be a corruption of *áshlūh* (pl. *ishláh*), a camel-hair tent. They are of fine physique, strong and wiry, and true Berbers in features and fairness.

SKIMMER, the name of aquatic birds of the genus *Rhynchops,* remarkable for the unique formation of the bill, in which the upper mandible is capable of vertical movement, while the lower is much longer and is laterally compressed like a knife-blade. This is adapted to its mode of feeding. By means of its lower mandible the bird may be said literally "to plough the main." The black skimmer, *R. nigra,* is found in North America. Other species occur in South America, India and Africa. The sexes are alike. In breeding-habits the skimmers agree with the terns (*q.v.*) to which they are related.

SKIN, SENSORY FUNCTIONS OF. It is the function of our senses to keep us in relation with our surroundings and to enable us to move with impunity about a world full of hard angular and dangerous objects. In this task the senses of the skin take an important and characteristic part. They occupy a position between what we may call the intimate senses of taste and smell on the one hand and the distant senses of sight and hearing on the other. In the former group the stimulating substance has to be brought into very close contact with the body and the mechanism of stimulation is probably chemical; in the latter group the stimulating agent may act from great distances. Unlike both these the skin gives us news chiefly of nearby events; it has nothing to tell us of the intimate chemical nature of objects and very little directly of distant things.

The external events which by acting on the skin arouse sensation are found to be for the most part the simple and obvious physical processes, mechanical and thermal.

Touch.—The feeling of contact or touch in the non-technical sense comprises two sensations. One of these, which is sharply localized in time and place and is in its essence delicate and exact, is touch in the strict technical sense. Its characteristic stimulus is movement at the surface of the skin. The other sensation is pressure; it is in its essence less precise and although well localized in place, is temporally indefinite so that the subject of it finds it impossible to decide by the sensation alone when a pressure stimulus has ceased. The characteristic stimulus of this sensation is simple static pressure.

True touch is probably the most elaborate product of evolution among the skin senses. It is interesting to notice that the essential neurological fact behind the tactile sense—that mere mechanical movement can be transmuted by the body into sensation—is also the fact on which the not more useful but far more imposing sense of hearing is based.

Thermal Sense.—Thermal sensations do not depend directly on the absolute temperature of the object that causes them but on its temperature relative to that of the skin. In other words the characteristic stimulus of the thermal sense is the interchange of heat between the stimulating object and the body. Sensations of warmth and heat are caused by heat passing into the skin, and sensations of coolness and cold by heat passing out of it. The intensity of the sensation varies with the rapidity of heat transference and therefore not only with the temperature difference but also with the conductivity for heat of the object. A good conductor therefore feels hotter or colder as the case may be than a bad conductor at the same temperature.

Most of our thermal sensations come to us by conduction through things actually touching the skin, including of course the air. The thermal sense is then usually, like the tactile sense, a short range process involving contact. Thermal sensations can however also be set up by radiated heat. Such radiation probably acts by warming the skin from which heat is then conducted in the ordinary way to the thermal nerve endings. It is conceivable however that these nerve endings are capable of direct response to the radiation. If this were so it would show the skin to possess the rudiment of a true long range sense, and perhaps a rudiment that by adaptation to higher frequencies of radiation has given us sight—the greatest of all the senses.

Pain.—The pain sense does not show the same simple and orderly relation between stimulus and sensation that is found with the tactile and thermal senses. Sensations of pain are set up by a heterogeneous group of stimuli which do not permit of any inclusive general physical or physiological description. It is of course obvious that any process that actually damages the skin is likely to cause pain at the moment of infliction though even this, as we shall see, is not an invariable rule. Many stimuli however, though at intensities giving clear sensation of pain, do not cause any perceptible injury—such for example are brisk heat and cold and the faradic current. The anomalous relation of stimulus and sensation to the possibility of injury is well seen in connection with radiant stimuli. Heat rays easily excite pain when too weak to cause injury as is shown in the sensitiveness of the ocular cornea to the radiation of a dull red fire. On the other hand the far more injurious ultra-violet and X-rays excite no sensation whatever even at the moment when they may be seriously damaging the skin. In general however it may be said that most of the stimuli capable of causing pain are such that if they were of but little increased intensity they would actually cause injury. From this it follows that the characteristic pain stimulus is of considerable energy—far greater in fact than that of the tactile or thermal stimulus—and that the pain sense in comparison with all others is a dull sense or has, in physiological terms, a high threshold.

However insensitive the mechanism may be, the sensation itself has a peculiarly vivid and explosive quality and differs from all other sensations in arousing in the subject of it a strong impulse to make some kind of motor response. The barely controllable flinching with which we suffer the mildest of pin-pricks is familiar evidence of this unique character of the pain sensation.

In comparison with other senses, pain then is seen to be highly anomalous. Its anomalies have been the subject of much theo-

retical discussion from which however no generally accepted doctrine has yet emerged.

Distribution of Sensibility.—It has long been known that the whole of a given area of skin is not equally sensitive. If its surface is explored with stimuli sufficiently fine, it is found that in some places no response is obtained to any stimulus and that sensitiveness is limited to certain small areas mostly less than a millimeter across. These spots are distinct for each kind of stimulus and respond to it only, so that there are separate spots for touch, heat, cold and pain.

The sensitiveness of a given region depends on whether the distribution of sensitive spots is thick or thin. As a general rule density of distribution varies together for all four senses so that a part sensitive to one stimulus is sensitive to all. To this however there are important exceptions. The skin of the face and the skin of the finger tip are both highly sensitive to touch but the latter is much the less sensitive to pain. A far more striking anomaly however is that certain regions—the cornea of the eye and a part of the glans penis—possess sensibility to pain only. It is difficult to give a functional explanation of this curious fact but it is interesting to note that these two regions have this in common that their embryological development includes a longitudinal splitting of the skin into two layers.

The Peripheral Sensory Mechanisms.—The sensory nerve fibres of the skin terminate in certain well-marked and minute structures called end-organs which are regarded as having the power to originate under appropriate stimulation the nerve-impulse which yields the characteristic sensation. These end-organs show a great variety of structure, but they are clearly divisible into two groups. First there is a group in which the end-organ consists of a mere breaking up of the nerve fibre into many fine naked branches among the cells of the part; this "terminal aborisation" is the end-organ of the pain nerve. Secondly there is a group the members of which though varying much have this in common—that the end of the nerve fibre is enclosed in a definite and often thick capsular structure. These end-organs are concerned with the sensations other than pain. This marked structural difference between the encapsuled or insulated and the naked or uninsulated end-organs is yet another peculiar character of the pain sense.

Into the intimate nature of the process whereby a stimulus to an end-organ causes an impulse in the nerve fibre we cannot as yet penetrate. The less exacting problem of what is the precise quality of the stimulus is as we have seen still unsolved for the pain sense. For the thermal and tactile senses the stimulus can be reduced to the simple physical processes of heat transference and movement respectively. In the case of touch we can even define in some detail the mechanisms by which very light touches are enabled to produce the movements which are essential to adequate stimulation of the touch-spots.

Each touch-spot is found to be placed close to a hair and the latter can be seen to move when the touch-spot is pressed on and sensation aroused. It is probable that the rigid root of the hair acts as a lever which magnifies the movement set up by the actual touch. The adequacy of the mechanism is shown by the experimentally established fact that the touch-spots of a rather coarse hairy skin are slightly more sensitive than those of a fine smooth skin. When the projecting part of a hair itself is gently touched a vague tickling sensation is felt quite unlike the clear light "pat" elicited by proper stimulation of a touch-spot. The hair is too flexible to transmit the whole movement intact to the end-organ and a sub-minimal stimulus results. This sensation of "tickle" is comparable with the sensation of itching which is probably the result of sub-minimal stimulation of pain nerves. It seems likely that the great reduction in hairiness shown by man's skin in comparison with that of other animals was favoured by the precision it gave to touch through the elimination of tickling sensations.

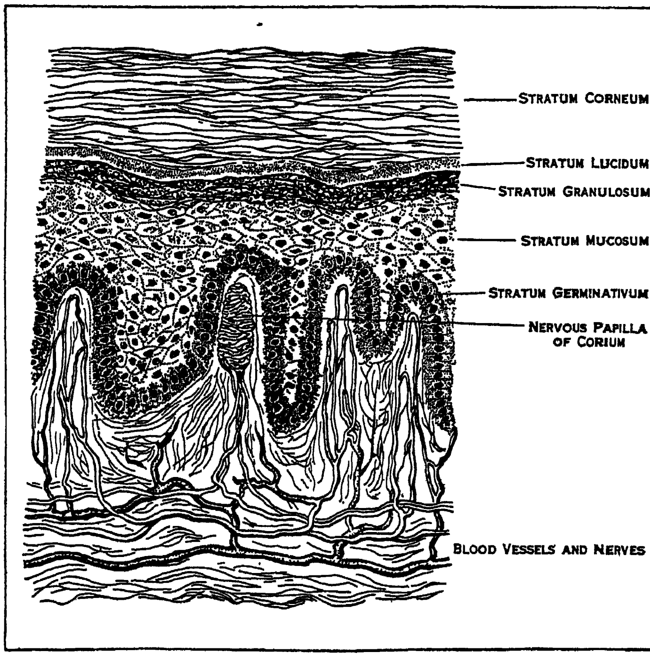
The hair bulb is then the ordinary means by which movement is transmitted to tactile end-organs. Where the skin is hairless however, as it is in some of its most sensitive parts, other mechanisms are necessary. The simplest substitute is to keep the surface layers of the skin flexible by reducing the amount of horny material in them and to keep them moist. This is the condition of the red surface of the lips which is highly sensitive to touch but at the expense of a high degree of vulnerability.

No such solution of the problem is possible in the fingers which must be kept sensitive and yet allowed a thick and horny protective covering. There the thick horny layer is grown on long closely parallel ridges with grooves between; the grooves are lines of diminished rigidity and permit the thick epidermis to remain highly flexible and therefore sensitive to touch. These ridges and grooves that by their individual uniqueness and constancy have proved so gratifying to the criminologist, are thus seen to have another and perhaps a higher function in serving the great sense of touch.

Bibliographical Note.—The sensory functions of the skin are not usually dealt with very fully in text-books of physiology. An elaborate account of the subject (with references to the work of other investigators) will be found in Sir Henry Head's "Studies in Neurology"—1920. A recent important contribution by Sir E. Sharpey-Schäfer appears in the *Quarterly Journal of Experimental Physiology*—August 1928.

SKIN AND EXOSKELETON, in anatomy. The skin is the covering of the whole body, and is continuous at the different orifices with the mucous membrane. It acts as a protective layer, as a regulator of the temperature, as an excretory organ and as a tactile and sensory organ in which nerves end.

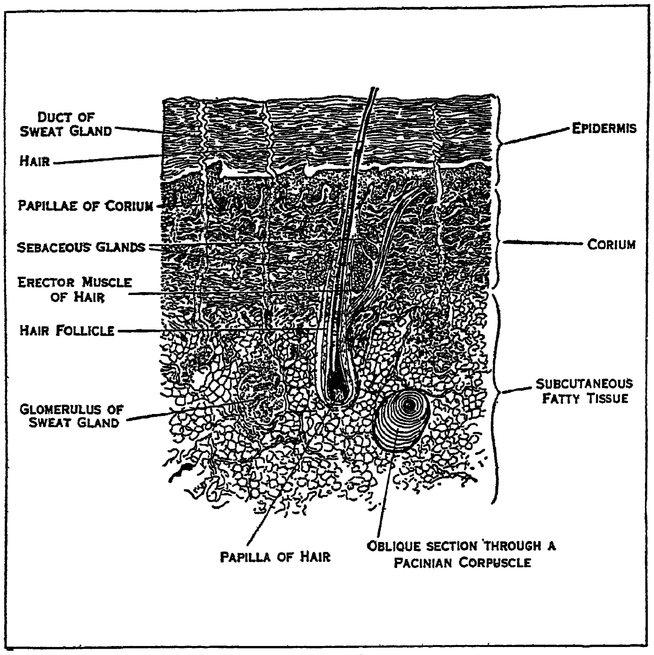
The skin varies in thickness from ·5mm. in the eyelids to 4 or more mm. in the palms and soles; it is also very thick over the back of the body. Two main layers are recognized, superficially the epidermis and more deeply the dermis or true skin. The *epidermis* under the microscope is seen to consist of five layers. On the surface is the horny layer or *stratum corneum* (*see* fig. 1) composed of layers of scale-like cells, the walls of which are turned into the horny substance keratin. Deep to this is a thin layer of scale-like cells without keratin known as the *stratum lucidum.* Deeper still is a layer, the *stratum granulosum,* in which the cells are not so flattened and contain granules of a substance known as eleidin. In the fourth layer, *stratum mucosum* or *stratum Malpighii,* the cells are polygonal and are connected together by delicate prickle-like processes. It is in the deeper layers of these cells that the pigment of the negro's skin is found. The fifth and deepest layer of the epidermis is the *stratum germinativum,* in which there is only one layer of columnar cells. The whole of the epidermis is non-vascular. The *true skin, dermis* or *corium* is composed of a felted network of white fibrous tissue with a small number of yellow elastic fibres interspersed. It is divided into two layers.



FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 1.—VERTICAL SECTION OF EPIDERMIS AND PAPILLAE OF CORIUM

The superficial or *papillary layer* lies next to the epidermis and is raised into a number of papillae or conical projections which fit into corresponding depressions on the deep surface of the epidermis. In sensitive parts like the palms and soles these papillae are specially prominent and form wavy lines, each of which consists of a double row between which the ducts of the sweat glands pass on their way to the surface. So large are the papillae in these situations that the epidermis is also raised into ridges, and these in the fingers form the characteristic whorls so valuable for purposes of identification. The papillae contain leashes of blood-vessels, and in some of them are special tactile corpuscles in which the nerves end (*see* NERVOUS SYSTEM).



FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 2.—VERTICAL SECTION OF THE SKIN

In the deeper or *reticular layer* of the true skin the fibrous feltwork is looser and encloses pellets of fat. It also contains a network of blood-vessels and nerves, and in some places a layer of striped or unstriped muscle. Where hairs are present the hair follicles lie in this deeper layer, which gradually merges with the subcutaneous fatty tissue (*see* fig. 2).

As appendages of the skin are found the hairs, the nails and the sebaceous and sweat glands.

Hair.—The hairs are found in man on the scalp, eyelids, eyebrows, armpits, pubic region, vestibule of the nose, external auditory meatus, face, ventral surface of the trunk and dorsal surfaces of the leg, forearm and hand; indeed the only places which are quite free from them are the palms of the hands, soles of the feet and the glans penis. In some places, such as the armpits, pubic region and the face of the male they grow to a considerable length at and after puberty. In section it is only the straight hairs which are circular; wavy and curly hairs are oval. In the centre of each hair is the medulla or pith, though this is not always present; it is composed of nucleated cells containing pigment, fat and air spaces. Outside this is the fibrous layer or cortex, also containing pigment and air spaces, while most superficially is the cuticle made up of overlapping scales. The hair grows at its root from a *hair follicle* (*see* fig. 2), which is a tubular inpushing of the epidermis into the true skin or, in the case of large hairs, deeper still into the superficial fascia. It is divided into an *inner* and *outer root sheath,* the former representing the more superficial layers of the epidermis, the latter the deeper layers. At the bottom of the follicle the hair enlarges to form the bulb, and into the lower part of this a vascular papilla projects from the true skin. The cells of the hair are derived from, and are continuous at the bulb with those of the outer root sheath, and therefore with the deeper layers of the epidermis.

The hair follicle always projects somewhat obliquely into the skin, and attached to the side toward which it is leaning is a small band of non-striated muscular fibres called *arrector pili.* When this acts it diminishes the obliquity of the hair and so makes it "bristle" or "stand on end," while a general contraction of these small muscles leads to the familiar condition of "gooseflesh."

Nails.—The nails are specially thickened parts of the epidermis, and are divided into a root and a body. The former is concealed by a fold of skin, and the corium on which it lies is known as the *nail matrix.* The body of the nail also lies on the corium, or true skin, which forms the *nail bed* and is very sensitive. This body of the nail is formed by the stratum germinativum and stratum mucosum in its deeper part, and more superficially by the stratum lucidum, which is here very much thickened and converted into keratin or horn. Near the root of each nail is a semilunar area which is more opaque than the rest and forms the white *lunula.*

Glands.—Sebaceous glands are found wherever there are hairs, however rudimentary, and open by their ducts into the superficial part of the hair follicle (*see* fig. 2). Their deeper or secreting part divides into a number of bag-like alveoli composed of cells, which secrete oil droplets. There may be two or three glands to each hair follicle, and their size does not vary directly with that of the hair, since they are very large in the nose, where the hairs are quite rudimentary. They are also found on the labia minora and nipples, where no hairs are. *Sudoriparous* or sweat glands (*see* fig. 2) are found all over the surface of the body, but are specially numerous on the palms and soles. It is estimated that in the palm there are nearly 3,000 to a square inch, while in the skin of the back they do not reach 500 to the same area. In the armpits and groins they are very large. Each consists of a single long tube, lined by columnar epithelium, and coiled up into a ball or glomerulus in the subcutaneous tissue, after which it pierces the corium and epidermis to reach the surface at the *porus sudoriferus.* Where the stratum corneum of the epidermis is thick the duct is twisted like a corkscrew as it goes through.

The *glands of Moll* in the eyelids and the ceruminous or wax glands of the ear are modified sweat glands; the former, when inflamed, cause a "sty."

EMBRYOLOGY

The skin is derived partly from the ectoderm and partly from the mesoderm of the embryo. The whole of the epidermis and its appendages are ectodermal, and in the early embryo consist of a single layer of cells; later on this becomes double, and the superficial layer, after the sixth month, is cast off and mixes with the secretion of the large sebaceous glands to form the soapy *vernix caseosa* with which the foetus is coated at birth. In the meantime the cells of the deeper layer divide and form the various layers of the epidermis already enumerated. The mesodermal cells belong to the mesenchyme, and form the fibrous tissue of the true skin as well as the arrectores pilorum muscles and, in the scrotum, the *dartos* layers of unstriped muscle. In the sixth month fatty tissue appears in the deeper parts, and so the fat of the superficial fascia or sub-cutaneous tissue is formed. The nails are said to appear as thickenings of the epidermis at about the ninth week, quite at the tips of the digits. Later on they shift to the dorsal side, and in doing so carry the nerves in the nail bed with them. This is the only explanation available of the fact that the ventral nerves to the tips of the fingers encroach on the dorsal area. By about the twelfth week the nails are perfectly formed, but they do not reach the level of the finger tips until the eighth month. The hairs are developed in the third month of foetal life by ingrowths of the stratum mucosum of the epidermis into the corium. During the fourth and fifth months the body becomes covered by fine unpigmented hairs which are known as *lanugo;* these begin to disappear about the eighth month, but some remain until after birth. On the scalp, however, the hair at birth is often more deeply pigmented than that which succeeds it. The sebaceous and sweat glands, like the hair follicles, are ingrowths of the stratum mucosum of the epidermis into the corium. The former become very large in the later months of embryonic life,

and secrete a large part of the above-mentioned vernix caseosa. The development of the mammary gland from modified sebaceous glands has already been referred to (*see* MAMMARY GLAND).

For further details *see* J. P. M'Murrich, *Development of the Human Body* (London, 1923); J. C. Heisler, *Text-book of Embryology* (London, 1907); Quain's *Anatomy*, vol. i. (London, 1908).

COMPARATIVE ANATOMY

In the larval (gastrula) stage of the Amphioxus (lancelet) cilia are present on the surface, and in the superficial epidermal cells of some fishes and amphibian larvae there is a striated layer on the free edge which is looked upon as a relic of ancestral cilia.

Skin Glands.—The skin glands of the Cyclostomata (hags and lampreys) and fishes are generally unicellular and secrete slime which protects the surface of the body. Some of the teleostean fish have poison glands at the bases of their dorsal fins and opercula.

In the mud fish (Dipnoi) and amphibians multicellular spherical glands appear as involutions of the ectoderm. Sometimes, as in the so-called parotids of the toad, these form large masses. Reptiles and birds are singularly wanting in skin glands, though the latter have a large *uropygial gland* at the root of the tail which secretes oil to lubricate the feathers; it is the chief constituent of the "parson's nose" of the fowl. In mammals, except the Cetacea, the sebaceous and sudoriparous glands already described in man are found; some of the former sometimes attain a large size, as in the interdigital gland of the sheep, Müller's gland at the back of the pig's knee and the suborbital gland of ruminants. In addition to these, special scent-producing glands are often found in different parts, the most remarkable of which, perhaps, are the scent glands beneath the tail of the skunk, while in male monotremes there is a special poison gland in the leg which is connected with a spur in the foot.

Pigment.—Pigment cells are present both in the dermis and epidermis of fishes and amphibians, and the pigment may be either intra- or extra-cellular. In many cases it is under the control of the nervous system, so that forms like the flat-fish and the common frog can adapt their colouration to that of their background. In animals permanently excluded from the light, pigment is absent. In reptiles movable pigment cells are often found, as in the chameleon, while in birds the pigment is sometimes of great brilliancy in the necks and wattles. In mammals, as in man, the pigment is confined to the cells of the stratum mucosum layer of the epidermis.

Scales.—In the elasmobranch fishes scales are found composed of enamel superficially, and of dentine and bone deeply. They are developed from the epidermis and dermis, and in almost every way resemble the teeth of these animals, which are only modifications of them. The bony basal part of each scale is plate-like, hence this kind of scale is known as *placoid*. In the ganoid fishes, such as the sturgeon, much larger plaques called *ganoid scales* form a complete armature. In the teleostean fishes the scales overlap like tiles and are either *cycloid*, having a smooth border, or *ctenoid*, in which the free posterior border is serrated. Existing amphibians are usually remarkable for absence of any skin armour, though in fossil forms (Stegocephala) it was very complete. The reptilian class is specially noticeable for the production of epidermal scales, which undergo many modifications. In the Ophidia they are cast off periodically in one mass as the snake's slough, while in the Chelonia they form the different varieties of tortoise-shell. Bony structures, developed in the dermis, may underlie these epidermal horny thickenings, and are very strongly developed in the dorsal and ventral bony shields of the Chelonia (carapace and plastron), which secondarily fuse with the true endoskeleton. The armadillo is the only mammal which has a true bony exoskeleton.

Feathers.—Birds are remarkable for the possession of feathers, which are highly modified scales. The embryonic or *down feathers* are simple, and consist of a brush of hair-like *barbs* springing from a basal quill or *calamus*. From the whole length of each barb a series of smaller *barbules* comes off like branches of a shrub. The adult or *contour feathers* are formed at the bottom of the same follicles which lodge the down feathers and, by their growth, push these out. At first they are nothing more than enlarged down feathers, but soon one of the barbs grows enormously, and forms a main shaft or *rachis* to which the other barbs are attached on either side. From the sides of the barbs grow the barbules, just as in the down feathers, and these, in the case of the large wing feathers (*remiges*) and tail feathers (*rectrices*), are connected by minute hooks so that the feather *vane*, as opposed to the shaft, has a more resistant texture than it has in the feathers of the back or breast. The bird's moult is comparable to the casting of the scales in the reptiles.

Hairs.—Hairs are only found in the mammalian class, and are divided into the long tactile bristles or vibrissae and the smaller hairs which maintain the warmth of the body. In some animals the hair of the body is composed of long, stiff hairs, which are probably specialized for protective purposes, and short, soft hairs, which form the fur and keep in the warmth. Sometimes these long hairs are greatly enlarged and hardened to form protective spines as in the porcupine, hedgehog, spiny mouse and spiny ant-eater (Echidna).

Horns.—Horns are of three kinds: (1) antlers, (2) hollow horns and (3) hairy horns of the rhinoceros.

Antlers are growths of true bone and, except for their very vascular covering of skin (velvet), are not exoskeletal structures. They grow with great rapidity, and in the deer family are renewed each year. As soon as their growth is finished the skin covering dries up and strips off. The small horns of giraffes are also bony structures though permanent.

The hollow horns of the ruminants (Bovidae) are cases of hardened epidermis which fit over a bony core and are permanent. They are found in both sexes, and in this differ from the antlers of the deer, which, except in the reindeer, are confined to the male. In the prongbuck (Antilocapra) the hollow horns are shed periodically.

The hairy horns of the rhinoceros are a mass of hairs cemented together by cells. The hairs grow from dermal papillae, but differ from true hairs in not being sunk into hair follicles.

Claws and Hoofs.—These are modifications of nails, but whereas in nails and claws the structures are confined to the dorsal aspect of the digits, in hoofs they spread to the plantar surface as well. It has been shown in the embryological section of this article that the nail appears at the very tip of the digit, and in this position it remains in many amphibians, *e.g.* giant salamander, while in hoofed mammals it develops both ventrally and dorsally. In the Felidae the claws are retractile, but the real movement occurs between the middle and terminal phalanges of the digits.

Spurs.—Spurs are quite distinct from nails and claws; they are very common in birds as horny epidermal sheaths covering bony outgrowths of the radial side of the carpus, metacarpus or metatarsus. The spur-winged goose has a carpal spur; in the screamers (Palamedea and Chauna) the spur or spurs are metacarpal, while in many gallinaceous birds (*e.g.* common fowls and pheasants) metatarsal spurs are found. In the mammals the male monotremes (Echidna and Ornithorhynchus) have spurs attached to an extra (? sesamoid) bone in the hind leg, perforated for the duct of the already mentioned poison gland.

Beaks.—Certain fishes belonging to the family Mormyridae have a fleshy prolongation of the lower lip, and are hence termed beaked fishes. In the Amphibia *Siren* and the tadpoles of most Anura (frogs and toads) have small horny beaks. In the Reptilia horny beaks are found in the Chelonia while in birds beaks are constant and replace the teeth in modern species. In mammals a horny beak is found in Ornithorhynchus, though it coexists with true teeth in the young and with horny pads in adult specimens. In all these cases the beaks are formed from cornified epidermal scales.

Baleen.—The baleen which is found in the mouths of the Balaenidae or whalebone whales is a series of flattened triangular horny plates arranged on either side of the palate. The inner edges and apices of these are frayed out into long fibres which act as strainers. In *Balaena mysticetus*, the Greenland whale, there are nearly four hundred of these plates, the longest of which often

exceed ten feet. In its development baleen resembles rhinoceros horn in that it consists of a number of epidermal hair-like fibres cemented together and growing from dermal papillae, though not from true hair follicles.

For further details and literature *see* R. Windersheim, *Comparative Anatomy of Vertebrates,* translated by W. N. Parker (London, 1907); S. H. Reynolds, *The Vertebrate Skeleton* (Cambridge, 1897). (F. G. P.)

SKIN DISEASES. The diseases of the skin do not essentially differ from those of the other organs of the body. But skin has certain differences from other organs, some dependent on its structure and some on its exposed position. There are no depths to be attacked, and any diseases, if they spread, must do so superficially; spreading as they often do equally in all directions, the diseases of the skin have a tendency to assume a circular form, independently of any parasitic cause, though when such cause is present the patches are of a more perfectly circular shape. Further, from the extent of its superficial area and its exposed position, the skin is liable to be attacked by more forms of irritation, parasitic or other, than any other organ of the body.

Classification.—The classification of skin diseases, at first based on naked-eye appearances, and, later, on the underlying pathological changes, is becoming simplified by the adoption of an etiological basis, and, as our knowledge of their causation becomes more complete, such an ideal becomes possible, and is being attempted in the more recent text-books. At the present time, however, the cause of certain skin diseases remains obscure, but, as the gaps in our knowledge become gradually filled in, the group of the unclassified affections becomes correspondingly diminished.

Of the new forms of skin disease which have been recognized in recent years, the most numerous have been those occurring in tropical countries, and of them a considerable number are due to fungi, and constitute the group of the tropical dermato-mycoses. In Great Britain the cutaneous lesions associated with diseases of the blood have been the subject of careful study, especially those which occur in connection with the leukaemias and lymphadenoma.

Ringworm.—It is now established that the disease, popularly known as ringworm, is due to a number of mould-fungi, which vary in different climates and countries, like other members of the vegetable kingdom, and have a wide distribution in the animal kingdom, occasionally even in birds, from which they are capable of being transmitted readily to man. Certain resistant forms of dermatitis, affecting various parts of the body, but more especially the groins and the extremities, which may closely resemble eczema, are not variants of that protean disease, but the result of the presence in the skin of certain ringworm fungi. This type of ringworm has increased since the World War, as it was common among the troops, especially those who went through the Gallipoli campaign, or served in the East, and was brought home and spread by them.

Eczema.—Eczema, the commonest of skin affections, is no longer regarded as a disease due to a single cause, but as a form of cutaneous reaction, due to a variety of irritants, acting either locally, from without, or circulating in the blood, possibly in an individual predisposed by some lowered resistance. In the group of the eczemas it is customary now to include the various forms of occupational dermatitis. These are attracting attention, as they are responsible for considerable disablement. The list of irritants, chemical and physical, which may cause them, is continually being extended, and the problem of their prevention is receiving the close attention of the Public Health Authorities (*see* INDUSTRIAL WELFARE).

Actinic Action.—The actinic rays of light have been shown to be an important factor in causing inflammation of the skin. For years it has been known that they are responsible for the peculiar eruption of the face and hands which recurs in summer in individuals sensitive to light (*Hydroa aestivale*), and for the more serious freckled affection which goes on to cutaneous cancer (*Xeroderma pigmentosum*). It is only recently, however, that the peculiar, dry, atrophic, freckled condition of the skin, dotted over with dilated capillaries, and horny thickenings which may become malignant, has been shown to be due to the sun's rays. This is met with on the unprotected parts, namely the arms, hands and face, of people long exposed to the sun, in countries where its rays are intense, such as India, South Africa, Australia, etc.; it is now designated as chronic solar dermatitis, and corresponds closely to a chronic burn from the X-rays. In Australia the ears of sheep sometimes develop cancer as the result of exposure to the sun's rays on the plains.

Microbial Action.—The rôle of micro-organisms and parasites in causing skin disease is highly important. Bacteria (*see* BACTERIOLOGY) have been shown to be the cause, not only of the common forms of septic impetigo, but of a variety of scaly affections, previously regarded as forms of eczema, which are now included under the heading of Dermo-épidermites microbiennes. Ultra-microscopic organisms, capable of passing through a Berkefeld filter, which have become prominent lately in connection with cancer (*see* CANCER; FILTER-PASSING VIRUSES), would seem to be responsible for the small epidermal growths, known as *Molluscum contagiosum,* and it is more than probable that similar organisms will be found to be the cause of other types of benign and malignant epithelial growths. In the Tropics, the so-called Calabar swellings have been found to be of filarial origin, and the Oriental sore to be due to a parasite of the trypanosome family.

Focal Infection.—Focal infection, in the sense of protein poisoning from bacteria in some crypt or tissue, or in the alimentary tract, has of late years been advanced as a possible cause of *Lupus erythematosus,* circumscribed patches of eczema, and other erythematous conditions, and the improvement in them which sometimes follows the injection of an autogenous vaccine has been taken as evidence of an etiological connection.

Nervous System.—Although certain affections of the skin, such as *Herpes zoster,* or shingles, have been proved to be of nervous origin, the trend of recent research has gone to show that the influence of the nervous system as a cause of cutaneous disease has been overrated, and that a number of affections, which were vaguely attributed to reflex nervous disturbances, are either of toxic origin, or due to imperfect action of a ductless gland, or to some disordered state of the blood.

Anaphylaxis.—The doctrine of anaphylaxis (*q.v.*) has contributed to our knowledge of certain cutaneous phenomena, and has explained the liability to recur of a dermatitis due to local irritation, or to the presence in the blood of some foreign protein.

Therapeutics.—Recent advances in treatment have been remarkable. Internal treatment has become based more on general medical principles and on the discovery and correction of some underlying disturbance in an organ or system than on so-called specific medication. That sheet-anchor of the earlier physicians—arsenic—has lost its position as a panacea for chronic skin affections, and any value it may have in the treatment of psoriasis, pemphigus, etc. is being regarded more as the result of its value as a nerve tonic than as a specific drug. It has attained, however, a new importance in its organic preparations, in the treatment of syphilis (*see* VENEREAL DISEASE).

Organo-therapy.—The increase in our knowledge of the ductless glands (*see* ENDOCRINOLOGY) has added organo-therapy to our methods of treatment, and thyroid medication has proved to be of benefit in various skin affections in childhood, associated with retarded development, and especially in mild ichthyosis, in which eczematous changes are so liable to be superimposed.

Vaccine Therapy.—The value of vaccines (*see* VACCINE THERAPY) in the treatment of skin diseases has been overrated, and their use in the past was too promiscuous. They are of most value in acute suppurating lesions of staphylococcic origin, such as recent boils. The development in local treatment has been even more striking than that from internal medication.

Refrigeration; Diathermy.—Refrigeration, with carbon dioxide as the freezing agent, is a useful means of destroying vascular naevi, moles, warts, superficial rodent ulcers, and of ameliorating Lupus erythematosus of the fixed type. Diathermy has proved of great value in inoperable cases of rodent ulcer, and for cauterisation of malignant growths in the mouth or naso-

pharynx (*see* ELECTRO-THERAPY).

Radiotherapy.—The greatest advances in late years, however, have taken place in connection with radiotherapeutics (*see* RÖNTGENOLOGY). The newer methods of X-ray dosage, made possible by the use of the Coolidge tube, have increased the usefulness of the X-rays as a means of healing chronic ulcers, relieving local irritations, reducing epidermal thickening and causing the defluvium of the hair for the cure of ringworm of the scalp. Radium has proved to be of special service in the treatment of rodent ulcers and hypertrophic scars (*see* RADIUM THERAPY). The value of the actinic rays of light, when applied locally, in the treatment of tuberculosis of the skin, and in healing chronic ulcers, has been greatly enhanced by its use over the whole cutaneous surface, in the form of actinic ray baths, which have been found to improve the general health by stimulating metabolism and increasing the bactericidal power of the blood. *See* HELIOTHERAPY.

SKINNER, JAMES (1778–1841), British soldier, born in India, son of Lieut.-Colonel Hercules Skinner and a Rajput lady, entered the Mahratta army under de Boigne and remained in the same service under Perron until 1803, when, on the outbreak of the Mahratta War, he refused to serve against his countrymen. He joined Lord Lake, and raised a regiment of irregular horse called "Skinner's Horse" or the "Yellow Boys," which became the most famous regiment of light cavalry in the India of that day. He died at Hansi on Dec. 4, 1841.

See J. Baillie Fraser, *Military Memoir of Lieut.-Colonel James Skinner* (1851).

SKINNER'S CASE, the name usually given to the celebrated dispute between the House of Lords and the House of Commons over the question of the original jurisdiction of the former house in civil suits. In 1668 a London merchant named Thomas Skinner presented a petition to Charles II. asserting that he could not obtain any redress against the East India company, which, he asserted, had injured his property. The case was referred to the House of Lords, and Skinner obtained a verdict for £5,000. The company complained to the House of Commons which declared that the proceedings in the other House were illegal. The Lords defended their action, and after two conferences between the Houses had produced no result the Commons ordered Skinner to be put in prison on a charge of breach of privilege; to this the Lords replied by fining and imprisoning Sir Samuel Barnardiston, the chairman of the company. Then for about a year the dispute slumbered, but it was renewed in 1669, when Charles II. advised the two Houses to stop all proceedings and to erase all mention of the case from their records. This was done and since this time the House of Lords has tacitly abandoned all claim to original jurisdiction in civil suits.

See Lord Holles, *The Grand Question concerning the Judicature of the House of Peers* (1689); L. O. Pike, *Constitutional History of the House of Lords* (1894); and H. Hallam, *Constitutional History,* vol. iii. (1885).

SKINS: *see* HIDES.

SKIPPON, PHILIP (d. 1660), English soldier, was born at West Lexham, Norfolk. At an early age he adopted the military profession and in 1622 served with Sir Horace Vere in the Palatinate. He took part in most of the battles and sieges of the time in the Low Countries. At the sieges of Breda in 1625 and 1637 he was wounded, and under his old commander, Lord Vere, he was present when Bois-le-Duc ('s Hertogenbosch) and Maestricht were attacked in 1629. A veteran of considerable experience, Skippon returned to England in 1639, and was appointed to a command in the (Honourable) Artillery Company. In January 1642 Skippon was made commander of the City troops. He was not present at Edgehill, but he cheered his raw militiamen at Turnham Green, in the face of the king's victorious army. Essex, the Lord General of the Parliament forces, made Skippon his major-general, a post which carried with it the command of the foot and the duty of arranging the line of battle. At the end of 1644 Essex's desertion at Lostwithiel left Skippon in command; compelled to surrender without firing a shot, he bore himself with calmness and fortitude in this adversity. Soon after the second battle of Newbury he became major-general of the New Model Army. In this capacity he supported Fairfax as loyally as he supported Essex, and at Naseby refused to quit the field. He only reappeared at the siege of Oxford, which he directed.

Under the Commonwealth he held office, military and civil, but ceased to influence passing events. He was a member of Cromwell's House of Lords, and was universally respected and beloved. He died in March 1660. Skippon was a deeply religious man, and wrote several books of devotion for the use of soldiers.

See Vicars, *English Worthies* (1647).

SKIPTON, an urban district in the West Riding of Yorkshire, 26 m. N.W. of Leeds, *via* the L.M.S., and Leeds and Liverpool canal. Pop. (1931) 12,434. It is situated in the hilly district of the upper valley of the Aire where it is joined by the Eller Beck from the north. It is the nodal town of the Craven Gaps, the lowest ways through the Pennines from Trent to Tyne, and so has become an important route centre, and the principal market town of Craven. During the middle ages, the Craven Gaps were the chief routes through the Pennines along which the Angles, and later the Danes, moved westwards, and Skipton was the capital of Craven. At the Norman conquest, it became part of the possessions of Earl Edwin and was granted to Robert de Romille, who built the castle in the 11th century. It was taken by the parliamentary forces in 1645 and was partly demolished in 1648, but was later restored; all that remains of the ancient Norman buildings is the west doorway of the inner castle. In the castle grounds are the remains of the chapel of St. John. The church of the Holy Trinity, mainly Perpendicular, was also partly destroyed during the Civil War, but has been restored. The grammar school was founded in 1548. There are woollen and cotton factories in the town, and a large limestone quarry near by. (M. K. M.)

SKIRRET, known botanically as *Sium Sisarum* (family Umbelliferae), a fleshy-rooted perennial, the roots of which are boiled, and afterwards served up like salsify.

SKOBELEV, MIKHAIL DIMITRIÉVICH (1843–1882), Russian general, was born near Moscow on Sept. 29, 1843. After graduating as a staff officer at St. Petersburg he was sent to Turkestan in 1868 and, with the exception of an interval of two years, during which he was on the staff of the grand duke Michael in the Caucasus, remained in Central Asia until 1877. He commanded the advanced guard of General Lomakine's column from Kinderly Bay, in the Caspian, to join General Verefkin, from Orenburg, in the expedition to Khiva in 1874, and, after great suffering on the desert march, took a prominent part in the capture of the Khivan capital. Dressed as a Turkoman, he intrepidly explored in a hostile country the route from Khiva to Igdy, and also the old bed of the Oxus. In 1875 he was given a command in the expedition against Khokand under General Kaufmann. For his great services he was promoted to be major-general and appointed the first governor of Fergana. In the Turkish War of 1877 he seized the bridge over the Sereth at Barborchi in April, and in June crossed the Danube with the 8th corps. He commanded the Caucasian Cossack Brigade in the attack of the Green Hills at the second battle of Plevna. He captured Lovtcha on Sept. 3, and distinguished himself again in the desperate fighting on the Green Hills in the third battle of Plevna. In command of the 16th Division, he took part in the investment of Plevna and also in the fight of Dec. 9, when Osman Pasha surrendered, with his army. In January 1878 he crossed the Balkans in a severe snowstorm, defeating the Turks at Senova, near Schipka, and capturing 36,000 men and 90 guns. Dressed in white uniform and mounted on a white horse, and always in the thickest of the fray, he was known and adored by his soldiers as the "White General." He returned to Turkestan after the war, and in 1880 and 1881 further distinguished himself in retrieving the disasters inflicted by the Tekke Turkomans, captured Geok-Tepe, and,

after much slaughter, reduced the Akhal-Tekke country to submission. He was advancing on Askabad and Kalat i-Nadiri when he was disavowed and recalled. He was given the command at Minsk. In the last years of his short life he engaged actively in politics, and made speeches in Paris and in Moscow in the beginning of 1882 in favour of a militant Panslavism, predicting a desperate strife between Teuton and Slav. He was at once recalled to St. Petersburg. He was staying at a Moscow hotel, on his way from Minsk to his estate close by, when he died suddenly of heart disease on July 7, 1882.

SKOPLJE, the capital of southern Serbia, Yugoslavia (Turkish *Usküb*). It lies on a fertile plain, with the Vardar running through it, and is completely encircled by a Turkish cemetery. Pop. (1921) 41,066, comprising Serbs, Albanians, Turks, Bulgars and a few gipsies. The agricultural production of the district includes maize, oats and barley, and silkworm culture is extensively carried on. There is an important opium market and Skoplje is the distributing centre for a very large area. At the outbreak of the World War (1914–18) it possessed a steam flour mill, a brewery, distilleries, tanneries, braid, soap, horseshoe and sugar factories, and was the centre of the silver filigree industry. The principal buildings are the citadel, the palace of the former Turkish governor, a Roman aqueduct, many churches and mosques, a School of Agriculture, an electric power station, an Institute of Tropical Diseases, two banks, several schools, including one for girls, and a university. The second urban Serbian school in Macedonia was opened here in 1830, and the first Macedonian newspaper published here in 1908. It is the seat of a Greek Orthodox bishop, a Roman Catholic and a Bulgarian bishop. Skoplje is the headquarters of one of the five Army provinces, and is strategically the most important point in Macedonia, and perhaps in the Balkans, several main arteries of communication, and four railways, converging upon it. Antimony, saltpetre, and veins of pure magnesite are found in the district and there is said to be much gold at Kara Dagh to the north.

The name is derived from *Scupi*, an ancient town whose ruins lie near by, and which was destroyed by an earthquake in 518, and rebuilt by Justinian. In the 13th century Skoplje was taken by King Milutin of Serbia and made his capital, and his successor, Stephen Dushan was crowned here in 1346, and here composed his famous Code.

SKOPTSI, a secret religious sect of Russia. It is an offshoot of the sect known as the "People of God" or *Khlysti* (*see* Russia: *Religion*). It was in 1771 in the government of Orel that the Skoptsi were first discovered by the authorities. A peasant, Andrei Ivanov, was convicted of having persuaded thirteen other peasants to castrate themselves. His assistant was another peasant, known as Selivanov. A legal investigation followed. Ivanov was knouted and sent to Siberia: Selivanov fled, but was arrested in 1775. Skoptsism, however, increased, and Selivanov escaped from Siberia and proclaimed himself the Son of God incarnate in the person of Peter III. Peter had been popular among the *Raskolniki* (schismatics, or dissidents) because he granted them liberty of conscience, and among the peasants because when pillaging the convents he divided their lands among the labourers. Selivanov claimed the title "God of Gods and King of Kings," and announced his accomplishment of the salvation of believers through a self-inflicted mutilation. For eighteen years he lived in St. Petersburg, in the house of one of his disciples, receiving double homage as Christ and tsar. In 1797 he was rearrested by order of Paul I. and imprisoned in a madhouse. Under Alexander I. Selivanov regained his liberty, but in 1820 was again shut up, this time in a monastery at Suzdal, where he died in 1832 in his hundredth year. Skoptsism was, however, not exterminated, and grave scandals constantly arose. The most remarkable feature of this extraordinary sect has always been the type of people who joined it. Nobles, military and naval officers, civil servants, priests and merchants were to be found in its ranks, and so rapidly did the numbers increase that 515 men and 240 women were transported to Siberia between 1847 and 1866 without seriously threatening its existence. In 1872 many trials of Skoptsi took place all over Russia. In 1874 the sect numbered at least 5,444, including 1,465 women. Of these 703 men and 160 women had mutilated themselves. Repressive measures proving useless, an unsuccessful attempt was made to kill the sect by ridicule: Skoptsi were dressed up in women's clothes and paraded with fools' caps on through the villages. In 1876 130 Skoptsi were sentenced in a batch to transportation. To escape prosecution some of the sect have emigrated, generally to Rumania, where they are known as Lipovans. Of late years, there is said to be a tendency among many Skoptsi to consider their creed fulfilled by chaste living merely.

SKOULOUDIS, STEPHEN (1836–1928), Greek statesman, a Chiot, was born an Ottoman subject, in Constantinople in 1836. He founded the Banque de Constantinople, and after retiring from business lived in Athens and became a Hellenic subject. He was several times elected member of the Greek chamber (1879 and 1892–1906). He was appointed minister in Spain in 1883, and minister of marine in the Trikoupis cabinet of 1892. As minister for foreign affairs in the Ralli cabinet of 1897, his knowledge of the Turks enabled him to exert his influence on the terms of peace after the war of 1897. He then resigned office, and retired into private life until 1912, when Venizelos obtained his appointment on the delegation to meet the Turks in London. In Nov. 1915 he became prime minister, in succession to Zaïmis. Soon after his appointment he announced his policy of benevolent neutrality. The confidence of the Allies was, however, shaken by his reported intention, at the instigation of German ministers, to disarm Serbian troops who were being forced into Greek territory by the German and Bulgarian advance, and the commercial blockade of Greece by the Allies (Nov. 18) was followed by an ultimatum which Skouloudis accepted. After six months' continued effort to satisfy both sides in the world conflict, Skouloudis resigned on June 19, 1916, shortly after the evacuation of Fort Rupel by the Greek garrison. A charge of treasonable correspondence was afterward brought against him, but was not proved. He died on Aug. 20, 1928.

SKOWHEGAN, the shire-town of Somerset county, Maine, U.S.A., on the Kennebec river, 40 m. N. of Augusta. It is on Federal highways 2 and 201, and is served by the Maine Central railroad. Pop. (1930) 6,433. The town has an area of 50 square miles. Water-power is abundant, and there is a large hydroelectric plant. The town manufactures woollens, worsteds, worsted yarns, shoes and various other commodities. Skowhegan was settled about 1770. It became a separate town in 1823, under the name of Milburn, and in 1836 adopted the old Indian name of the locality, said to mean a "spearing" or "watching" place.

SKRAM, PEDER (*c.* 1500–1581), Danish senator and naval hero, born between 1491 and 1503, at his father's estate at Urup near Horsens in Jutland. He first saw service in the Swedish war of Christian II. at the battle of Brannkyrka, 1518, and at the battle of Uppsala two years later he saved the life of the Danish standard-bearer. For his services he was rewarded with an estate in Norway. During "Grevens Fejde," or "the Count's War," Skram was sent by the Danish government to assist Gustavus Vasa, then in alliance with Christian III. against the partisans of Christian II., to organize the untried Swedish fleet; and Skram seems, for the point is still obscure, to have shared the chief command with the Swedish Admiral Måns Some. Skram greatly hampered the movements of the Hanseatic fleets who fought on the side of Christian II., captured a whole Lübeck squadron off Svendborg, and prevented the revictualling of Copenhagen by Lübeck. But the incurable suspicion of Gustavus I. minimized the successes of the allied fleets throughout 1535. Skram's services were richly rewarded by Christian III. As a senator he contributed to the victory of the Danish party over the German in the councils of Christian III. In 1555, feeling too infirm to go to sea, he resigned his post of admiral; but when the Scandinavian Seven Years' War broke out seven years later, the new king, Frederick II., offered Skram the chief command.

He put to sea in August 1562, and compelled the Swedish admiral, after a successful engagement off the coast of Gotland, to take refuge behind the Skerries. He was superseded at the end of the year by Herluf Trolle. Skram was twice (1565–1568) unsuccessfully besieged by the Swedes in his castle of Laholm, which he and his wife defended with great intrepidity. Skram died at Urup on July 11, 1581.

Skram's audacity won for him the nickname of "Denmark's dare-devil," and he contributed perhaps more than any other Dane of his day to destroy the Hanseatic dominion of the Baltic. His humanity was equally remarkable; he often imperilled his life by preventing his crews from plundering.

See Axel Larsen, *Dansk-Norske Heltehistorier* (Copenhagen, 1893).

SKRZYNECKI, JAN ZYGMUNT (1787–1860), Polish general, organised the Polish army at the revolution of 1830. After his defeat by Diebitsch at Ostrolenka he had to resign his command. He took refuge at Cracow, where he died.

SKRZYNSKI, ALEXANDER, Count (1882–), Polish statesman, was born at Zagorzany, Galicia. Educated at Cracow and Munich, he entered the diplomatic service in 1906 and was appointed secretary to the ambassador to the Holy See in 1910. When the World War broke out he was secretary to the Austro-Hungarian Ambassador in Paris. After a short military service at the beginning of the War, he completed his studies for the Bar, receiving the degree of Doctor of the Law at the University of Vienna. When the new Polish State was established, he was appointed Polish Minister Plenipotentiary at Bucharest, and later succeeded in concluding a Polish-Rumanian political treaty in 1921. In Dec. 1922, after the murder of Narutowicz, the first international President of the Republic, Skrzynski became Minister of Foreign Affairs. He threw himself energetically into the task of settling all open questions, inaugurated a pacific policy based on the final stabilisation of frontiers and gained the necessary confidence of the Powers. When a Cabinet of the Right was formed in May 1923, Skrzynski thereby lost office, and he was appointed in the following month Polish delegate to the League of Nations. In Aug. 1924 he again became Minister of Foreign Affairs in the Grabski Cabinet.

By a number of conventions, the regulation of the British and American debts, the concordat with the Vatican, the rapprochement with Czechoslovakia, Skrzynski strengthened Poland's international position, taking an active part in the League of Nations in elaborating the scheme for the Geneva Protocol and in securing settlement of the Danzig disputes in a manner favourable to Poland. He tried to disarm the suspicions of Moscow as to the new configuration of Europe by receiving Chicherin at Warsaw (Sept. 1924). In the negotiations in connection with the German proposals with regard to the Locarno Pact (1925), Skrzynski sought to reconcile Polish interests with the general scheme of the conference, and signed an arbitration agreement with Germany and also a convention with France in accordance therewith. After the fall of Grabski's Government Nov. 13, 1925, Skrzynski was entrusted with the formation of a government by Wojciechowski, the President of the Republic, and with the participation of the Socialists formed a coalition cabinet in which he himself was Prime Minister and Minister of Foreign Affairs. In May 1926, however, the Socialists seceded from the Cabinet on account of the refusal of their financial proposals, which involved inflation. After the Pilsudski *coup d'état* of that month Skrzynski remained in retirement. *See* also Poland.

SKUA, sea-birds forming the genus *Stercorarius* of the *Laridae* (*see* Gull). Except during the breeding season, when they obtain their own food, the skuas live almost exclusively by preying upon gulls, which they compel to disgorge what they have caught. For this purpose they are swift of flight, powerfully armed and endowed with great courage. The largest species, equalling a herring gull (*Larus argentatus*) in size, is *S. skua,* the great skua or bonxie. The plumage is dark brown above, lighter beneath, with a patch of white at the base of the primaries. It breeds in the Faeroes, Shetlands, and Iceland, laying its two dark olive eggs in a nest in the heather. Out of the breeding season it occurs all over the north Atlantic. *S. antarcticus,* the Port Egmont hen, from the Pacific, closely resembles it. Maccormick's skua (*S. maccormicki*) breeds on the Antarctic continent, where it plunders the penguin colonies.

The Arctic or Richardson's skua (*S. crepidatus*) is interesting as showing great variety in the colour of the underside from dark to white, with a thin dark collar. In the Arctic, skuas nest only in years when food is plentiful. The skuas have a remarkable injury-feigning performance to lure intruders from the nest. If this does not succeed, they swoop at the intruder's head. Some species may strike severe blows. American ornithologists assign three of the skuas, which they call jaegers, to the genus *Stercorarius:* the pomarine jaeger (*S. pomarinus*), the parasitic jaeger (*S. parasiticus*), and the long-tailed jaeger (*S. longicaudus*).

SKULL, the skeleton of the head, composed of 22 bones, 8 of which form the skeleton of the cranium, 14 that of the face. Except the lower jaw, which is movable, the bones are united by immovable joints. In the following article the skull is considered as a whole, and for this purpose a normal European skull is studied from in front, from above, from the side, from behind and from below. Afterwards the interior is considered by means of sections.

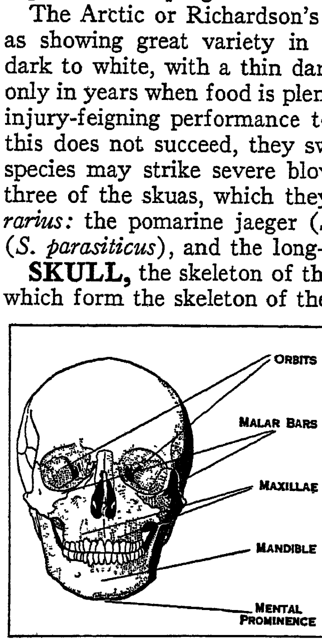

Fig. 1.—Skull, full faced

The Skull from in Front (*see* fig. 1).—The forehead region is formed by the frontal bone, the two halves of which usually unite in the second year. The lower limit of the forehead is formed by the upper margin of the orbit on each side, and by the articulation between the frontal and nasal bones near the mid line. At the junction of the inner and middle third of each supra-orbital margin is the supra-orbital notch for the nerve of that name. Above each supra-orbital margin is an elevation, better marked in adult males, called the supra-ciliary ridge, while between these ridges in the middle line there is a slight prominence, the *glabella.* Below the forehead the two *nasal bones* form the skeleton of the upper part of the nose; they articulate with one another in the mid line, but laterally they are joined by a suture to the nasal processes of the maxillae which run up to articulate with the frontal at the internal orbital process, thus forming the inner margin of the orbit.

Externally the malar bones articulate with the frontal at the external orbital process and form the lower and outer quadrant of the orbital margin.

The *maxillae* or upper jaws form the greater part of the skeleton of the face; they complete the lower and inner quadrant of the orbit, and below the nasal bones leave the anterior nasal aperture between them, and project slightly at the middle of the lower border of this aperture to form the anterior nasal spine. About a quarter of an inch below the infra-orbital margin and just below the articulation with the malar the *infra-orbital foramen,* for the infra-orbital branch of the fifth nerve, is seen on each side. The lower parts of the maxillae form the *alveolar margin* in which all the upper teeth are set. Laterally each maxilla is prolonged out into the *zygomatic process,* which supports the malar bone.

Below the maxillae the *mandible* or lower jaw is seen in perspective. The horizontal part or body is in two halves up to the second year, but after that complete bony union takes place, forming the symphysis. Above the body of the mandible is an alveolar margin containing the sockets of the lower teeth, while below, near the mid line, the bone projects forward to a variable extent and so forms the *mental prominence,* one of the special characteristics of a human skull. Below the second bicuspid tooth on each side is the *mental foramen* for the exit of the mental branch of the fifth nerve.

The Orbit.—Each orbit is a pyramidal cavity, the base of the pyramid being in front and the apex behind, at the optic foramen, where the optic nerve and ophthalmic artery pass through. The four sides of the pyramid form the roof, floor, inner and outer

walls of the orbit. The roof and floor are arched from side to side, the inner wall is antero-posterior and parallel with its fellow of the opposite orbit; the outer wall slopes backward and inward, the two opposite sides therefore converge as they run back. Seven bones enter into the composition of the orbit, viz. the frontal, sphenoid, maxilla, malar, lacrymal, ethnoid and palate. Between the roof and the outer wall, behind, is a slit in the *sphenoidal fis-*

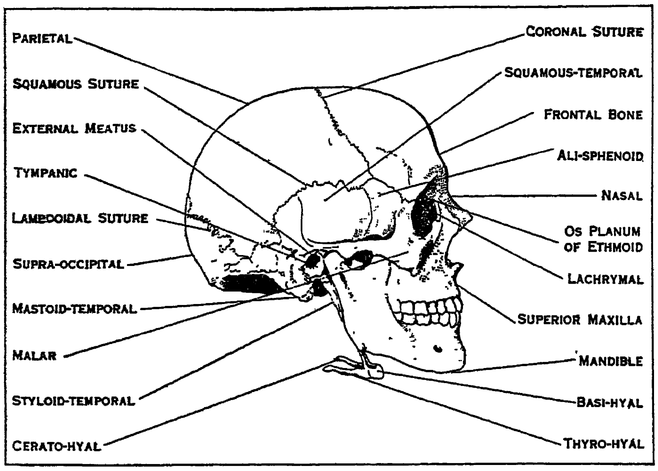

FIG. 2.—PROFILE OF THE SKULL

sure which transmits the third, fourth, first division of the fifth and sixth cranial nerves and the ophthalmic vein. Another slit (*spheno-maxillary fissure*) lies in the line of junction of the outer wall and floor, it leads into the spheno-maxillary and zygomatic fossae and transmits the second division of the fifth nerve and some veins.

The Skull from Above.—When looked at from above the frontal bone is seen forming the anterior part of the vertex and articulating with the two parietals posteriorly by a nearly transverse serrated suture (*coronal suture*). Running back from the middle of this is the median *sagittal suture* extending as far as the lambda behind. The point where the sagittal and coronal sutures join is the *bregma,* the site of the lozenge-shaped *anterior fontanelle* in the infant's skull, but this closes during the second year of life. Small ossicles called *Wormian bones* are often found in the cranial sutures. About two-thirds of the way back the sagittal suture becomes less serrated and on each side the small *parietal foramen* may be seen. This only transmits a small emissary vein (*see* VEINS) in the adult, but, as will be seen later, is of morphological interest. As middle life is reached, the cranial sutures tend to become obliterated and the bones can no longer be separated; this fusion begins at the places where the sutures are least deeply serrated, and as a rule the sagittal suture disappears between the two parietal foramina between thirty and forty years of age.

The Skull from the Side (fig. 2).—The *calvaria* or brain case forms all the upper part, while the face is below the anterior half. Taking the calvaria first the side view of the frontal bone extends back as far as the coronal suture. On each side is an elevation, *the frontal eminence,* better seen in female than in male skulls. The junction between the frontal and malar at the outer margin of the orbit (*external angular process*) is an important landmark for measurements, and from it a curved line (the temporal crest) runs back crossing the coronal suture to reach the parietal bone; as it runs back this line divides into two. The quadrilateral outline of the parietal bone is seen as well as its articulations; above it touches its fellow of the opposite side; in front, the frontal; below, the great wing of the sphenoid or alisphenoid, the squamous part of the temporal and the mastoid part of the temporal, while behind it articulates with the supra-occipital, through the lambdoid suture. All four angles of the parietal are points of special interest; the antero-superior angle or *bregma* lies nearly above the ear opening or *external auditory meatus* in the temporal bone. The antero-inferior angle where the frontal, parietal and alisphenoid meet is the *pterion* and is the site of an occasional Wormian bone. The posterior superior angle is the lambda and is better seen behind while the posterior inferior angle, where the parietal, supra-occipital and mastoid temporal bones meet, is known as the *asterion* and marks the lateral sinus within the cranium. A little above and behind the middle of the parietal bone, and just above the superior temporal crest, is the *parietal eminence* where ossification starts. The *squamous part of the temporal bone* overlaps the parietal at the *squamous suture,* while from its lower part the *zygomatic process* projects forward to articulate with the malar. At the root of this process is the *glenoid cavity* where the condyle of the lower jaw articulates, and just behind this is the *external auditory meatus.* Behind this again the mastoid temporal is prolonged down into a nipple-shaped swelling, the *mastoid process,* containing air cells and only found in the adult human skull, while just in front of the external auditory meatus is the *styloid process,* connected with the hyoid bone by the stylo-hyoid ligament (dotted). In the side view of the face the nasal and maxillary bones are seen, and from this point of view it will be noticed that just below the nasal aperture the maxillae, where they join, are produced forward into a little spur, *the anterior nasal spine,* which is a purely human characteristic. At the side of the maxilla the lozenge-shaped *malar* bone is placed; it forms the anterior part of the zygomatic arch. When the mandible is disarticulated and removed the posterior part of the maxilla is seen, and behind it the *external pterygoid plate* of the sphenoid. Between these two bones there is a vertical slit-like opening into a cave, the *spheno-maxillary fossa,* which communicates with the orbit through the *spheno-maxillary fissure,* with the nasal cavity through the *spheno-palatine foramen,* with the cranial cavity through the *foramen rotundum,* and with the mouth through the *posterior palatine canal,* as well as having other smaller openings.

The side view of the *mandible* or lower jaw shows the body, and the ramus projecting up from the back part of it at an angle of from 110° to 120° in the adult. Before the teeth come and after they are lost the angle is greater. At the upper part of the ramus are two projections; the most anterior is the *coronoid process* for the attachment of the temporal muscle, while posteriorly is the *condyle* which articulates with the glenoid cavity of the temporal bone.

The Skull from Behind.—From this point of view the posterior ends of the parietal bones, with the sagittal suture between them, are seen. Below these comes the *supra-occipital bone* separated from them by the *lambdoid suture* which is deeply serrated and a frequent site of Wormian bones. Where the sagittal and lambdoid sutures meet is the *lambda.* In the mid line about a hand's breadth (2¾–3in.) below the lambda is the *external occipital protuberance* or *inion,* for the attachment of the *ligamentum nuchae,* while running out on each side from this are the *superior curved lines* which attach muscles of the neck.

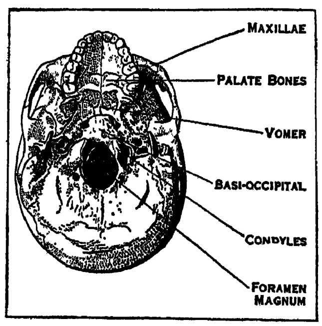

FIG. 3.—SKULL FROM BELOW

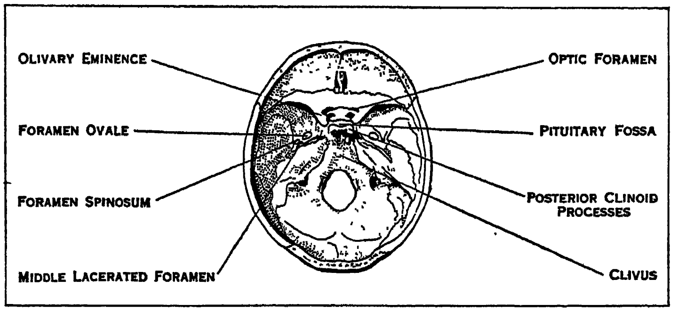
The Skull from Below (fig. 3).—Starting from in front, the *superior alveolar arcade* with the teeth sockets is seen. This in a European skull approaches a semicircle, but in lower races the sides become more parallel. Within the arcade is the *hard palate* formed by the maxillae in front, and the palate bones behind. At the front of the median suture between the maxillae is the *anterior palatine canal.* In young skulls a suture runs outward from the anterior palatine canal to between the lateral incisor and canine sockets, and sometimes another runs from the same place to between the central and lateral incisor teeth.

At each postero-lateral angle of the palate are the posterior palatine canals for the descending palatine nerves. The posterior margin of the hard palate is a free edge which forms the lower boundary of the *posterior nasal apertures* and attaches the soft palate (*see* PHARYNX). Behind the alveolar arcade on each side are the *external* and *internal pterygoid plates* of the sphenoid;

the external is a muscular process for the attachment of the pterygoid muscles, while the internal ends below in the hook-like hamular process which is directed backward and outward. Dividing the posterior nasal aperture into two is the vertical hind edge of the *vomer,* which articulates above with the body of the sphenoid (basi-sphenoid), and just behind this the sphenoid is united by bone with the basioccipital, though up to twenty years of age there is a synchrondrosis (*see* JOINTS) called the *basilar suture* between them. Passing back in the mid line the *foramen magnum* is seen, through which pass the spinal cord and its membranes, the vertebral arteries and the spinal accessory nerves. A little in front of this is a small tubercle, the *pharyngeal spine,* to which the constrictors of the pharynx are attached. On each side of the foramen magnum and in front of its mid transverse diameter are the condyles, which articulate with the atlas, while just above these are the *anterior condylar foramina,* one on each side, for the exit of the hypoglossal nerves.

External to the pterygoid plates the base of the skull is formed by the ali-sphenoid, which projects backward into a point, *the spine of the sphenoid,* and just in front of this is the small *foramen spinosum* for the passage of the middle meningeal artery. In front and a little internal to the foramen spinosum is a larger opening, the *foramen ovale,* through which the third division of the fifth nerve leaves the skull. Into the re-entering angle between the ali-sphenoid and basi-occipital is fitted the *petrous part of the temporal,* which, however, does not quite fill the gap but leaves a space on each side of the site of the basilar suture to be closed in by fibro-cartilage, and this is known as the *middle lacerated foramen.* On the lower surface of the petrous bone is the round opening of the *carotid canal* through which the internal carotid artery and its accompanying sympathetic nerves pass into the skull, while more externally the *styloid process* projects downward and forward. Between the styloid process and the occipital condyle lies the *jugular* or *posterior lacerated foramen* through which pass the lateral and inferior petrosal sinuses, and the glosso-pharyngeal, vagus and spinal accessory nerves. The bone which bounds this foramen behind, and bears the posterior two-thirds of the occipital condyle, is the *ex-occipital* part of the occipital. A little behind and external to the styloid process is the tip of the mastoid process, just internal to which is the deep antero-posterior groove for the digastric muscle, and internal to that another slighter groove for the occipital artery. Behind the styloid process and between it and the mastoid is the stylo-mastoid foramen through which the facial nerve passes, while in front of the process the glenoid cavity can be seen in its entirety, bounded in front by the *eminentia articularis* and divided into an anterior part and a posterior *tympanic plate* by the *Glaserian fissure.* Just internal



FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 4.—BASE OF THE SKULL SHOWING INTERNAL ASPECT

to the glenoid cavity is the opening of the bony *Eustachian tube.*

The posterior part of the base behind the foramen magnum is formed by the *supra-occipital* part of the occipital bone, so that all the four parts of the bone, which are separate up to the third year, help in the formation of that large opening. Between the foramen magnum and the external occipital protuberance and superior curved line already noticed, the bone attaches the deep muscles of the neck.

The Interior of the Cranium (fig. 4).—If the roof of the skull be sawn off the interior or cerebral surface of both the vault and the base may be examined. The vault shows the cerebral aspects of parts of the frontal, parietal and occipital bones, and of the sutures between them. In the mid line is a shallow antero-posterior groove for the superior longitudinal blood sinus, and on each side of this irregular depressions are often seen for the Pacchionian bodies (*see* BRAIN). The *base* is divided into three fossae, anterior, middle and posterior, each being behind and on a lower level than the one in front of it.

The *anterior cranial fossa* is formed by the *cribriform plate of the ethmoid,* near the mid line, freely perforated for the passage of the olfactory nerves. In the mid line, near the front, is a triangular plate rising up which attaches the falx cerebri (*see* BRAIN) and is called the *crista galli.* On each side of this is the *nasal slit* for the nasal branch of the first division of the fifth nerve. On each side of the cribriform plate is the *orbital plate* of the frontal, while the back part of the fossa has for its floor the body of the sphenoid (pre-sphenoid) near the mid line and the lesser wing (*orbito-sphenoid*) on each side. Each lesser wing is prolonged back into a tongue-like process, the *anterior clinoid process,* just internal to which is the *optic foramen,* and the two foramina are joined by the *optic groove* for the optic commissure. Behind this groove is a transverse elevation, the *olivary eminence,* which marks the junction of the *pre-* and *basi-sphenoid* parts of the body of the sphenoid bone.

The *middle cranial fossa* is like an hour-glass placed transversely, as there is a central constricted, and two lateral expanded, parts. The central part forms the *pituitary fossa* for the pituitary body (*see* BRAIN) and is bounded behind by the wall-like *dorsum sellae,* at the sides of which are the *posterior clinoid processes.* The olivary eminence, pituitary fossa and dorsum sellae together resemble a Turkish saddle and are often called the *sella turcica.* The lateral expanded part of the middle cranial fossa is bounded in front by the great wing of the sphenoid (alisphenoid), behind by the front of the petrous part of the temporal (*periotic*) and laterally by the squamous part of the temporal (*squamosal*). Between the alisphenoid and orbitosphenoid is the *sphenoidal fissure* already noticed in the orbit, and a little behind this, piercing the alisphenoid, is the posterior opening of the *foramen rotundum,* through which the second division of the fifth nerve passes into the spheno-maxillary fossa. Further back the alisphenoid is pierced by the foramen ovale and foramen spinosum, both of which have been already noticed. From the latter a groove for the middle meningeal artery runs forward and outward, and soon divides into anterior and posterior branches, the former of which deepens into a tunnel near the pterion. At the apex of the petrous bone and at the side of the dorsum sellae is the *middle lacerated foramen,* already noticed, and running inward to this from an aperture in the petrous bone is a groove for the great superficial petrosal nerve which is overlaid by the Gasserian ganglion of the fifth nerve.

The *posterior cranial fossa* is pentagonal in outline, having an anterior border formed by the dorsum sellae, two antero-lateral borders, by the upper borders of the petrous bones, and two postero-lateral curved borders, by the grooves for the lateral sinuses. In the middle of this fossa is the foramen magnum. In front of the foramen magnum the floor of the fossa is formed by the basi-occipital and basi-sphenoid bones, which unite soon after twenty and form a steep slope, downward and backward, known as the *clivus.* This is slightly grooved from side to side, and lodges the pons and medulla (*see* BRAIN) and the basilar artery.

On each side of the basi-occipital the posterior surface of the petrous bone bounds the fossa, and lying over the suture between them is the groove for the inferior petrosal venous sinus which leads backward and outward to the *jugular foramen* already noticed. About the middle of the posterior surface of the petrous bone is the *internal auditory meatus,* through which pass the facial and auditory nerves, the pars intermedia (*see* NERVES, CRANIAL) and the auditory artery. Close to the antero-lateral part of the foramen magnum is the inner opening of the *anterior condylar foramen* which is sometimes double for the two bundles of the hypoglossal nerve, and a little in front of and outside this is a heaping up of bone called the *tuberculum jugulare,* which marks

the union of the basi- and ex-occipital bones. The hindmost limit of the posterior fossa in the mid line is marked by an elevation called the *internal occipital protuberance,* and at this point the grooves for the superior longitudinal, and two lateral sinuses join to form the *torcular Herophili* (*see* VEINS). Running from the internal occipital protuberance toward the foramen magnum in the mid line is the *internal occipital crest,* which attaches the

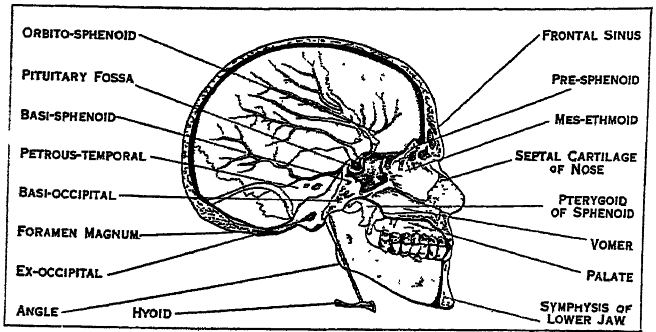


FIG. 5.—SECTION THROUGH THE SKULL IMMEDIATELY TO THE RIGHT OF THE MESIAL PLANE

falx cerebelli (*see* BRAIN) and on each side of this is the cerebellar fossa.

From the internal occipital protuberance the two wide grooves for the lateral venous sinuses run nearly horizontally outward till they reach the posterior inferior angles of the parietal bones; here they turn downward with an **S**-shaped curve, grooving the mastoid portion of the temporal and later on the exoccipital bones, until they reach the jugular foramina. To the edges of the horizontal parts of these grooves, and to the upper edge of the petrous bones the tentorium cerebelli is attached.

The Skull in Sagittal Section.—If the skull be sawn down just to the right of the mid line and the left half be looked at, the appearance will be that reproduced in fig. 5. The section of the cranial bones shows that they are formed of an *outer* and *inner table* of hard bone, while between the two is a layer of cancellous tissue called the *diploë.* In certain places the diploë is invaded by ingrowths from the air passage which separate the two tables and form the air sinuses of the skull, though it is important not to confuse these with the intracranial blood or venous sinuses. In the section under consideration two of these spaces, the *frontal* and the *sphenoidal air sinuses* are seen. Behind the frontal sinus is the *crista galli* already mentioned, while below is the bony septum of the nose formed, by the *mes-ethmoid plate,* the *vomer* and the line of junction of the palatine processes of the two maxillae and two palate bones. The re-entering angle between the mes-

FIG. 6.—OSSIFICATION OF SPHENOID

ethmoid and vomer is filled in the recent state by the septal cartilage.

Below the face is the inner surface of the body and ramus of the *mandible,* and half-way down the latter is the *inferior dental foramen* where the inferior dental branch of the fifth nerve accompanied by its artery passes into the *inferior dental canal* in the substance of the bone to supply the lower teeth.

If the cut surface of the right half of the skull be looked at, the outer wall of the nasal cavity will be seen with the three turbinated bones each overhanging its own meatus, but the anatomy of this part has already been dealt with in the article on the olfactory system (*q.v.*).

For further details *see* any standard anatomical textbook—Quain, Gray, Cunningham, etc.

EMBRYOLOGY

The *notochord* (*see* SKELETON: *Axial*) extends forward to the ventral surface of the middle cerebral vesicle (*see* BRAIN) or as far as the place where the dorsum sellae will be. It is partly surrounded by the mesenchyme just as it is completely in the rest of the axial skeleton, and this mesenchyme extends dorsally on each side to wrap round the nerve cord, which is here the brain. In this way the brain becomes enclosed in a primitive membranous cranium, the inner part of which persists in its primitive condition as the dura mater, while the outer part may chondrify, chondrify and ossify, or ossify without a cartilage stage. On each side of the notochord a basicranial plate of cartilage is formed which soon meets its fellow of the opposite side, and forms the floor of the skull as far forward as the dorsum sellae, and as far back as the external occipital protuberance. Laterally it comes in contact with the mesenchyme surrounding the internal ear, which is also chondrifying to form the cartilaginous *periotic capsule,* and the two structures fuse together to form a continuous floor for the back of the skull. In the hinder occipital region of the calf there are evidences of four vertebrae having been incorporated with the basicranial plate, that is to say that the plate and its coalesced vertebrae represent five mesodermic somites. The same is true for man. Moreover, the primitive membranous skull shows signs of metameric segmentation in the way in which the cranial nerves pierce the dura mater one behind the other. These segments, however, had lost their distinctness even before the cartilaginous cranium had become developed, so that there is no real segmental value in the elements of this, still less in those of the bony skull. The only place in which segmental elements can be distinguished is in the occipital region, which is in structure transitional between the head and vertebral column. The notochord, it has been shown, ends just behind the place where the stomodaeum pouches up through the cranial base to form the anterior part of the pituitary body (*see* BRAIN). Where it ends two curved bars of cartilage are formed, which run forward till they meet the olfactory capsules, which are also now chondrifying. These bars are the *prechordal cartilages* or *trabeculae cranii* and enclose between them the *cranio-pharyngeal canal* by which the pituitary body ascends, but later on, as they grow, they join together and cut off the pituitary body from the pharynx. By the growth outward they form the floor of the prechordal part of the chondro-cranium, so that from them is developed that part of the cartilaginous skull which will later on be part of the basisphenoid, the presphenoid, orbitosphenoid and alisphenoid regions. It was assumed that this process held good for man, but later research showed that the anterior part of the base of the skull chondrifies in the same way that ice appears on a pond and that the trabeculae are at no time definite structures. Chondrification of the nasal capsules is later than that of the parts of the skull behind, so that there is a steady progress in the process from the occipital to the ethmoidal region. There is a median centre of chondrification, the *mesethmoid cartilage,* which projects down into the fronto-nasal process (*see* OLFACTORY SYSTEM), and two lateral *ectethmoid cartilages* which eventually join with the mesethmoid to form the cartilaginous ethmoid.

The cartilaginous base of the cranium is now formed, but the vault is membranous. While the base has been developing the two anterior visceral arches have been also forming and have gained an attachment to the cranium, but the formation and fate of these is recorded in the article SKELETON (*Visceral*). About the sixth week of foetal life ossification begins at different points in the membranous vault of the skull. In this way the frontal, parietal, supra-occipital, and a little later the squamous part of the temporal bones are formed. About the eighth week, too, the lachrymal, nasal and vomer appear in the membrane lying superficial to different parts of the olfactory capsule. All these are dermal bones, comparable to the deeper parts of the scales of fishes, and developed in the mesenchyme lying deep to and in contact with the ectoderm. It is therefore necessary to think of the primitive skull as a three-layered structure, the deepest layer persisting as

the dura mater, the middle forming the chondro-cranium, which ossifies to form the base, and a superficial layer close to the skin or mucous membrane (ectoderm), from which the bones of the vault and superficial parts of the olfactory capsules are derived. At the four angles of the parietal, ossification is checked for some time to form *fontanelles,* of which the *bregma* is the most important, and at each of these points, as well as elsewhere in the sutures, accessory centres of ossification may occur to form *Wormian bones.*

Along the middle line of the base of the skull the same progress of ossification from behind forward is seen that was noticed in the process of chondrification. Bilateral centres for the basioccipital appear about the sixth week, for the basisphenoid in the eighth, and for the presphenoid in the tenth, while the lateral mass of the ethmoid does not ossify till the fifth month and the mesethmoid not until the first year of extrauterine life. In the lateral part of the base the exoccipitals and alisphenoids begin to ossify about the eighth week and the presphenoids about the tenth. In connection with the alisphenoid there is a small extra centre of morphological interest only, which forms a little tongue-shaped process called the *lingula,* projecting back into the middle lacerated foramen and apparently corresponding to the *sphenotic* bone of lower vertebrates.

The auditory or *periotic capsule,* like the olfactory, is late in ossifying; it has four centres (pro-otic, epiotic, opisthotic and pterotic) which do not come until the fifth month.

Some parts of the chondro-cranium do not ossify at all; this is the case in the anterior part of the mesethmoid, which remains as the septal cartilage of the nose, while, as has been already pointed out, a buffer of cartilage persists between the basioccipital and basisphenoid until the twentieth year of life.

From what has been said it is evident, and it will be still more evident if the article Skeleton (*Visceral*) be looked at, that some of the bones of the adult skull are compounded of various contributions from the different elements which make up the adult cranium. These, recapitulated, are (1) the dura mater or endocranium, which in man does not ossify except perhaps in the crista galli. (2) The chondro-cranium or mesocranium. (3) The superficial part of the mesenchyme (ectocranium) from which dermal bones are formed. (4) The olfactory and auditory sense capsules. (5) The visceral arches. (6) Some fused vertebrae posteriorly.

The occipital bone (fig. 7) for example, has the basioccipital, exoccipital and basal part of the supra-occipital derived from the

FIG. 7.—OSSIFICATION OF OCCIPITAL BONE

chondro-cranium and fused vertebrae, while the vault part of the supra-occipital has four dermal centres of ossification corresponding to the interparietal and preinterparietal bones of lower mammals. The bone of Kerkring is an abnormality, the meaning of which is not understood.

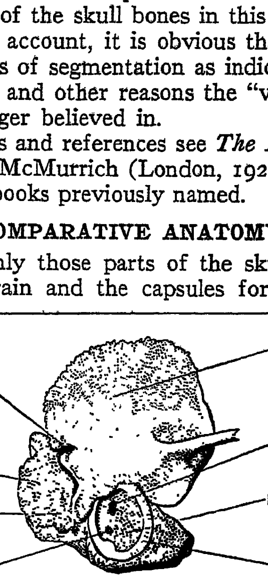
The temporal (fig. 8) is also a very composite bone; in it the petro-mastoid portion represents the auditory sense capsule; the tabular external auditory meatus is formed by the outgrowth of the tympanic ring which is probably part of the first visceral arch (*see* Skeleton, *Visceral*); the squamo-zygomatic part is a dermal bone, while the styloid process is a part of the second visceral arch.

The mastoid process is not present at birth, but appears about the second year and becomes pneumatic about puberty. From what has been seen of the skull bones in this necessarily concentrated and abridged account, it is obvious that they do not correspond to the traces of segmentation as indicated by the cranial nerves, and for this and other reasons the "vertebrate theory of the skull" is no longer believed in.

For further details and references see ***The Development of the Human Body,*** J. P. McMurrich (London, 1923) and other standard anatomical textbooks previously named.

COMPARATIVE ANATOMY

In this section only those parts of the skull which form the covering for the brain and the capsules for the olfactory and



FROM ARTHUR THOMPSON IN CUNNINGHAM, "TEXTBOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 8.—OUTER SURFACE OF THE RIGHT TEMPORAL BONE AT BIRTH

auditory apparatus are considered. Those parts of the face and jaws which are developed in connection with the visceral arches are dealt with in the article Skeleton (*Visceral*). In the Acrania (Amphioxus) the enlarged anterior end of the nerve cord is merely surrounded by fibrous tissue continuous with the sheath of the rest of the nerve cord; there is therefore, in a sense, no true cranium.

In the Cyclostomata (hags and lampreys) a cartilaginous cranium is developed, the anterior part of which forms an unpaired olfactory capsule connected with the rest of the cranium by fibrous tissue only. In the floor, just in front of the anterior end of the notochord, an aperture; the *basi-cranial fontanelle,* remains unchondrified for the passage of the pituitary diverticulum into the skull.

In the Elasmobranchii (sharks and rays) and Holocephali (Chimaera) among the fishes the skull is still a complete cartilaginous box, though calcification of the cartilage often takes place. Taking the skull of the dogfish as a type, two large olfactory capsules are seen in front, and behind these the cranial brain-box is narrowed, being excavated at its sides for the great orbits. More posteriorly the auditory capsules widen the skull, and on the posterior (caudal) aspect the foramen magnum is seen with an occipital condyle on each side of it for the first vertebra to articulate with. On the upper (dorsal) surface of the skull are two apertures in the middle line; the more anterior of these forms a rudimentary median orbit for the pineal eye (*see* Brain). The posterior fontanelle is a depression which leads into two lateral tubes, each of which passes into the auditory capsule and is known as an *aqueductus vestibuli* (*see* Ear).

In the cartilaginous ganoid fishes (sturgeon), which, like the elasmobranchs, are of great antiquity, the chondro-cranium is partly ossified so that ali- and orbito-sphenoids are found; in addition to this a large number of dermal bones have made their appearance, such as *nasals, frontals, parietals, supra* and *post temporals,* while in the roof of the mouth and pharynx a long membrane bone, the *parasphenoid,* is formed, and lies ventral to and strengthens the cartilaginous base of the skull. These fish are important morphological landmarks, because in them the almost unchanged chondro-cranium coexists with a dermal ectocranium.

In the bony ganoids such as the "bow fin" (Amia) the dermal bones are still more numerous and, among others, squamosals, pro-otics and exoccipitals appear. These fish are also remarkable for a fusion of the anterior part of the vertebral column with the

occipital region of the skull, an arrangement recalling that in the skull of the calf embryo mentioned in the section on embryology.

In the bony fishes (Teleostei) the membrane or dermal bones are still more numerous, and many of them are unrepresented in the mammalian skull, while others, which are there quite rudimentary, are very large. The chondro-cranium tends to disappear in the vault, but the base is fully ossified. Among other cartilage bones the five ossifications of the auditory capsule are seen, the pro-, epi-, opisth-, pter- and sphen-otics, all of which are found as centres of ossification in man. In the cod, for example, the sphenotic, which is represented in man by the little lingula sphenoidalis, is larger than the alisphenoid.

In the Dipnoi (mud-fish) the chondro-cranium is very slightly ossified, only exoccipitals being found, but there is the same coalescence with anterior vertebrae which was noticed in the ganoids. Dermal bones are plentiful.

In the Amphibia the chondro-cranium persists and is only ossified in front by the girdle bone or sphenethmoid, and behind by the pro-otics and exoccipitals, the latter of which bear the two condyles. The anterior fontanelle is well marked in the chondro-cranium, but is completely overlaid and concealed by the dermal fronto-parietals. The membrane bones though large are much less numerous than in the bony fishes.

In the Reptilia the skull varies immensely in the different orders, but speaking broadly, the chondro-cranium is less distinct than in the Amphibia, except in the ethmoidal region. In the base of the skull the basioccipital and basisphenoid are tending to replace the membranous parasphenoid, and instead of two exoccipital condyles only one in the mid line is present, though this in many forms (*e.g.*, Chelonia) consists of three parts, a median borne on the basioccipital and two lateral on the exoccipitals. The parietal foramen is usually definitely marked in the dermal part of the skull and forms a median orbit for the pineal eye; this is especially the case in the Lacertilia (lizards). Except in the Ophidia (snakes) and Amphisbaenidae (worm-like lizards) there is a fibro-cartilaginous septum between the orbits so that the cranial cavity does not reach forward to the ethmoidal region. The pro-, epi- and opisthotic bones are all developed, but the epiotic usually fuses with the supra-occipital and the opisthotic with the exoccipital.

In the Crocodilia the first attempt at pneumaticity is seen in the basisphenoid, which is traversed by a complicated system of Eustachian passages leading eventually to the tympanum. In the class Aves the general scheme of the reptilian skull is maintained, though the bones fuse together very early, thus obliterating the sutures between them. Almost all of them have air in their interior, and so are said to be pneumatic.

The single occipital condyle, if looked at in a young specimen, is seen to consist of a basioccipital and two exoccipital elements, though these are indistinguishable in the adult. The parasphenoid is represented by a broad plate which is called the basitemporal. The pro-, epi- and opisth-otic bones fuse together to form the auditory capsule.

In the Mammalia the calvaria varies considerably in the different orders, the characteristic features being best marked in adult males. Usually the different bones are interlocked by sutures, as in man, until adult life, but in some orders (*e.g.*, Monotremata, Edentata and Carnivora) they fuse together quite early.

In the basicranium the cartilage bones presphenoid, basisphenoid and basioccipital, are so well developed that the parasphenoid has disappeared. In the basisphenoid of the rabbit the craniopharyngeal canal (*see* section on embryology) persists as a foramen at the bottom of the pituitary fossa. In the lower orders the face lies well in front of the brain case, as it does in reptiles and amphibians, but as the Primates are reached the increasing size of the calvaria causes it to overlie the face. Many of the bones are pneumatic, the process reaching its maximum in the elephant and the adult male gorilla. The periotic capsule blends with the squamosal and tympanic to form the petrous bone, though it is practically only in man that the second visceral arch ossifies on to this as a styloid process. There are usually two occipital condyles which have basi- and exoccipital elements, though there are many mammals in which there is one large crescentic condyle surrounding the anterior half of the foramen magnum.

Ossification of the processes of the dura mater occurs in the tentorium cerebelli of the carnivora and in the falx cerebri of the ornithorhynchus and porpoise. The orbits are in most mammals continuous with the temporal fossae. Sometimes, as in many of the ungulates and in the lemurs, they are outlined by a bony ring, but it is not until the higher Primates are reached that the two cavities are shut off and even then a vestige of their original continuity remains in the spheno-maxillary fissure.

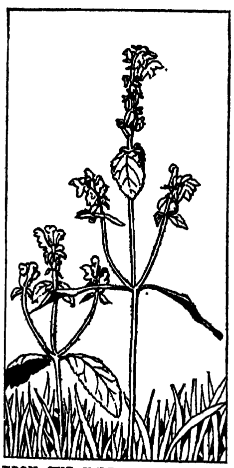
SKULL, SURGERY OF. Fractures of the vault of the skull may occur without the bone being driven in to compress the brain, and in such cases their existence may be revealed only after death. But if there is also a severe scalp wound the line of fracture may be traced in the bare bone as a thin red crack. The patient with a suspected fracture of the skull is put to bed in a dark, quiet room, and is watched. It may be that the crack has extended across a bony groove in which an artery is running, and, the artery being torn, haemorrhage may take place within the skull and symptoms of compression of the brain may supervene.

Compression of the brain may be the direct and immediate result of a head-injury, a piece of the vault of the skull being driven in, and a local or a general paralysis of muscles being at once observed. In addition to the muscular paralysis, there may be insensibility, laborious breathing, dilated pupils that do not react to light. In such cases the treatment is trephining.

Fractures of the base of the skull are always serious, in that they may run across important nerves and large blood-vessels; passing through the roof of the nose, or the ear, they may communicate with air-cavities. Thus, the dangers of sepsis are added to those of concussion or compression of the brain. Fractures of the base of the skull are often associated with bleeding from the nose, mouth or ear, or with extravasation of blood over the eyeball. Facial paralysis is the result of the line of fracture passing across the bony channel in which the seventh or facial nerve is running. When the fracture passes across the temporal bone and the middle ear, and ruptures the membrane of the tympanum, not only blood may escape from the ear, but an apparently unlimited amount of cerebro-spinal fluid. When the fracture extends through the anterior part of the base of the skull this same clear fluid may escape from the nose. In both cases its appearance implies that the dura mater has been lacerated and the sub-dural space opened.

Concussion of the brain (stunning) may result from a blow upon the head or from a fall from a height. The symptoms may be those of mere giddiness and a feeling of stupidity, which may quickly pass off, or they may be those of severe shock (*see* Shock). The person may die from the concussion, or he may slowly or quickly recover. As a rule, the pupils react to light. One of the first signs of returning consciousness is that the person vomits, and after this he gradually comes round. As a result of the injury, however, he may remain irritable, liable to headache or to lapses of memory. *See* also Brain, Surgery of.



FROM THE WILD FLOWER PRES. SOC.

SKULL-CAP (SCUTELLARIA), AN HERB COMMON IN DAMP AND SHADY PLACES

SKULL-CAP (*Scutellaria*), the common name for a numerous genus of herbs and subshrubs of the mint family (Labiatae, *q.v.*), comprising some 200 species of nearly world-wide distribution. They have numerous blue, violet, yellow, scarlet or white flowers, borne in opposite pairs or in axillary or terminal, slender, one-sided spikelike racemes. The corolla has a long tube, dilated at the throat and surmounted with two unequal lips, the upper usually entire and the lower notched. The persist-

ent calyx bears a conspicuous protuberance on the upper lip, giving it a helmet-like appearance, whence the common name. Two species occur in the British Isles, the common or marsh skull-cap (*S. galericulata*), with handsome violet-blue flowers, and the lesser skull-cap (*S. minor*). Besides the common skull-cap, which is found across the continent, some 25 other species occur in North America.

SKUNK, a North American carnivorous mammal, belonging to the family *Mustelidae* and noted for its evil smell arising from a secretion of the anal glands. This is under the control of the animal, which can propel the yellow liquid to a distance of 8 or 12ft. The common skunk (*Mephitis mephitica*) inhabits North America from Hudson bay to Texas and eastward. About the size of a cat, though more heavily built, it has black fur, with a streak of white on the back. The muzzle is long and pointed, the white tail long and bushy. Insects form its staple diet, but it will also eat mice, eggs, frogs, and carrion, and occasionally rob hen-roosts. The skunk evinces little dread of man or other animals, and its normal gait is a walk. No animal attacks it knowingly, and its leisurely gait and conspicuous coloration well advertise its disagreeable properties. During very severe weather the animal hibernates. Six to ten young are brought forth each spring. Several other forms inhabit Central and South America. (*See* C. H. Merriam, *Mammals of the Adirondack Region;* W. H. Hudson, *A Naturalist in La Plata.*)

THE COMMON SKUNK

It lives in dens or burrows, and is chiefly nocturnal in its habits. Since colonial times, it has been trapped, and sometimes reared for its valuable fur. *See* U.S. Dept. Agr. Reports Bulletins. Com. Reports on Fur Production Census.

SKUNK CABBAGE (*Symplocarpus foetidus* or *Spathyema foetida*), a fleshy herbaceous plant of the arum family, Araceae (*q.v.*), so called because of its fetid odour and large leaves, native to eastern North America and north-eastern Asia. It grows in swampy places and in very early spring (March or sometimes February) it sends up from thick rootstocks grotesque, swollen, shell-like, purple-brown spathes, each enclosing many small flowers borne in a short thick cluster. These are soon followed by numerous ovate leaves, 1 to 3 ft. long, and later by large globular masses of fleshy berries. The similar western skunk cabbage (*Lysichiton kamtschatcense*) occurs from California to Alaska and also in Siberia.

SKY, the apparent covering of the atmosphere, the overarching heaven. (M.Eng. *skie,* cloud; O.Eng. *skua,* shade; connected with an Indo-European root *sku,* cover, whence "scum," Lat. *obscurus,* dark, etc.)

The Colour of the Sky.—It is a matter of common observation that the blue of the sky is highly variable, even on days that are free from clouds. The colour usually deepens toward the zenith and also with the elevation of the observer. It is evident that the normal blue is more or less diluted with extraneous white light, having its origin in reflections from the grosser particles of foreign matter with which the air is usually charged. Closely associated with the colour is the *polarization* of the light from the sky. This takes place in a plane passing through the sun, and attains a maximum about 90° therefrom. Under favourable conditions more than half the light is polarized.

As to the origin of the normal blue, very discrepant views have been held. Some writers, even of good reputation, have held that the blue is the true body colour of the air, or of some ingredient in it such as ozone. It is a sufficient answer to remark that on this theory the blue would reach its maximum development in the colour of the setting sun. It should be evident that what we have first to explain is the fact that we receive any light from the sky at all. Were the atmosphere non-existent or absolutely transparent, the sky would necessarily be black. There must be something capable of *reflecting* light in the wider sense of that term.

A theory that received much support in the past attributed the reflections to thin bubbles of water, similar to soap-bubbles, in which form vapour was supposed to condense. According to it, sky blue would be the blue of the first order in Newton's scale of colours. The theory was developed by R. Clausius (*Pogg. Ann.* vols. 72, 76, 88), who regarded it as meeting the requirements of the case. It must be noticed, however, that the angle of maximum polarization would be about 76° instead of 90°.

Apart from the difficulty of seeing how the bubbles could arise, there is a formidable objection, mentioned by E. W. Brücke (*Pogg. Ann.* 88, 363), that the blue of the sky is a much richer colour than the blue of the first order. Brücke also brought forward an experiment of great importance, in which he showed that gum mastic, precipitated from an alcoholic solution poured into a large quantity of water, scatters light of a blue tint. He remarks that it is impossible to suppose that the particles of mastic are in the form of bubbles. Another point of great importance is well brought out in the experiments of John Tyndall (*Phil. Mag.* [4], 137, 388) upon clouds precipitated by the chemical action of light. Whenever the particles are sufficiently fine, the light emitted laterally is blue in colour and, in a direction perpendicular to the incident beam, is *completely plane-polarized.*

The dependence of the amount of scattering upon the wave-length of the light can be settled in the case of very small particles by an application of the method of dimensions. The particle acts as a centre for a radiating beam. The amplitude of the light sent out by it at a distance R varies inversely as R; it is also proportional to the volume of the particle when this is small compared with the wave-length of the light. Thus the ratio of the scattered to the incident *intensity* varies as $\frac{V^2}{R^2}$; that is a quantity whose dimensions are those of the fourth power of a length. The ratio of intensities must, however, be a pure number; and since the wave length λ is the only other linear quantity that can be concerned, the ratio must also depend on the inverse fourth power of λ.

Lord Rayleigh's Theory.—A more detailed investigation was conducted by the third Lord Rayleigh (*Phil. Mag.* XLI., 107, 275) based on an elastic-solid theory of light. This enquiry showed that both the intensity and the polarization could be satisfactorily accounted for on such a theory, if (and only if) the vibrations are perpendicular to the plane of polarization and the difference between the substance of the particles and that of the surrounding medium is one of density only.

Later (*Phil. Mag.* XII. 81–101, 1881) Rayleigh examined the question from the point of view of the electromagnetic theory in which the particles are treated as dielectric spheres. Maxwell's equations can be applied exactly in the case of vanishingly small spheres. The azimuth of the electric displacement travelling in any direction in the scattered wave is at right angles to that direction and is in the plane containing the scattered *ray* and the azimuth of the incident *displacement;* further the intensity is proportional to the square of the sine of the angle between these two lines. It follows that when this angle is zero the scattered light in the given direction is zero. This occurs in the direction at right angles to the incident ray. Thus, in this case, if unpolarized light is incident the light scattered at right angles is completely polarized.

According to either theory, sunlight in penetrating through the earth's atmosphere should fall off according to an exponential law for each colour.

In order to test the theory Rayleigh compared the bl[illegible] of the sky taken from near the zenith with sunligh[illegible] through white paper. For different wave-lengths the [illegible] culated from the formula are given together with obse[illegible] for comparison:—

Fraunhofer line	C	D	b_3	[illegible]
Calculated	25	40	63	[illegible]
Observed	25	41	70	9[illegible]

It appears that the sky light when compared with that diffused through white paper was bluer than that required by theory; but this may possibly arise from yellowness of the paper or from the yellowness of the sunlight when it reaches us compared with its colour at higher levels.

A much more important calculation has reference to the size and number of the particles concerned in the production of the blue of the sky. Since the light scattered by each particle is proportional to the *square* of its volume the total amount scattered per unit volume depends not only upon the quantity of matter therein but upon its fineness of division also. Assuming that the *molecules* of the air are the effective scatterers Rayleigh in 1899 calculated (taking Maxwell's value 19×10^{18} for the number of molecules per unit volume of a gas at standard pressure and temperature) that sunlight should diminish to $\frac{1}{e}$ of its value in passing through a distance of 83 kilometres in normal air. This value might agree roughly with the visibility of Mount Everest from Darjeeling but Rayleigh considered that it implied too high a visibility since there is certainly suspended matter to be reckoned with as well. Small particles of saline or other matter (including organic germs) must play a part and to them may be attributed much of the bluish haze by which the moderately distant landscape is often suffused.

American Investigations.—In recent years considerable attention has been paid to this question in America where advantage could be taken of the remarkable clearness and dryness of the air above Mount Wilson in California. F. E. Fowle in these investigations has obtained values of the transparency coefficients for zenith observations for 30 different wave-lengths between $0{\cdot}34\ \mu$ and $2{\cdot}24\ \mu$ (μ = one millionth of a metre). The logarithms of the observed coefficients were plotted as ordinates against the corresponding quantities of precipitable atmospheric moisture as abscissae. The curves which were very nearly straight were extrapolated to zero moisture so as to obtain the transparencies for perfectly dry air. From these values for dry air the number of molecules per c.c. was calculated by means of Rayleigh's formula. The value obtained was $2{\cdot}7\times10^{19}$, while the best value obtained by Millikan by other methods is $2{\cdot}705\times10^{19}$. The conclusion drawn from this result is that for the clear air above Mt. Wilson the scattering is almost entirely due to the molecules of air themselves. (Fowle, *Astroph. J.* 1914.)

Tyndall's Residual Blue.—The experiments of Tyndall upon precipitated clouds have been mentioned. When the precipitated particles are very fine, the light dispersed in a perpendicular direction is sky-blue and fully polarized. At a further stage of their growth the particles disperse in the perpendicular direction a light which is no longer fully polarized. When quenched as far as possible by rotation of a nicol prism, it exhibits a residue of a more intense blue colour; and further it is found that the direction of the most nearly complete polarization becomes inclined to the direction of the primary rays.

Electromagnetic Theory.—A discussion of these and other questions upon the basis of the electromagnetic theory of light is given in the *Phil. Mag.*, 1881, 12, p. 81. Here we must be content with a statement of some of the results. So long as the particles are supposed to be very small and to differ little from their environment in optical properties, there is little difference between the electric and the elastic solid theories. Whatever may be the shape or size of the particles, there is no scattered light in a direction parallel to the primary electric displacements. In order to render an account of Tyndall's "residual blue" it is necessary to pursue the approximation further, taking for simplicity the case of spherical shape. We learn that the light dispersed in the direction of primary *vibration* is not only of higher order in the difference of optical quality, but is also of order k^2c^2 in comparison with that dispersed in other directions, where c is the radius of the sphere, and $k=2\pi/\lambda$. The incident light being white, the intensity of the component colours scattered in this direction varies as the inverse *eighth* power of the wave-length, so that the resultant light is a rich blue.

As regards the polarization of the dispersed light as dependent on the angle at which it is emitted, we find that although, when terms of the second order are included, the scattered light no longer vanishes in the same direction as before, the peculiarity is not lost but merely transferred to another direction. The angle θ through which the displacement occurs is measured backwards, *i.e.*, towards the incident ray, and its value is given by

$$\theta=\frac{\Delta K}{K}\,\frac{k^2c^2}{25}, \tag{23}$$

ΔK being the difference of dielectric constants.

Experiments upon this subject are not difficult. In a darkened room a beam of sunlight (or electric light) is concentrated by a large lens of 2 or 3 ft. focus; and in the path of the light is placed a glass beaker containing a dilute solution of sodium thiosulphate (hyposulphite of soda). On the addition, well stirred, of a small quantity of dilute sulphuric acid, a precipitate of sulphur slowly forms, and during its growth manifests exceedingly well the phenomena under consideration. The more dilute the solutions, the slower is the progress of the precipitation. A strength such that there is a delay of 4 or 5 minutes before any effect is apparent will be found suitable, but no great nicety of adjustment is necessary.

Polarization.—In the optical examination we may, if we prefer it, polarize the primary light; but it is usually more convenient to analyze the scattered light. In the early stages of the precipitation the polarization is complete in a perpendicular direction, and incomplete in oblique directions. After an interval the polarization begins to be incomplete in the perpendicular direction, the light which reaches the eye when the nicol is set to minimum transmission being of a beautiful blue, much richer than anything that can be seen in the earlier stages. This is the moment to examine whether there is a more complete polarization in a direction somewhat oblique; and it is found that with θ positive there is, in fact, a direction of more complete polarization, while with θ negative the polarization is more imperfect than in the perpendicular direction itself.

The polarization in a distinctly oblique direction, however, is not perfect, a feature for which more than one reason may be put forward. In the first place, with a given size of particles, the direction of complete polarization indicated by (23) is a function of the colour of the light, the value of θ being 3 or 4 times as large for the violet as for the red end of the spectrum. The experiment is, in fact, much improved by passing the primary light through a coloured glass. Not only is the oblique direction of maximum polarization more definite and the polarization itself more complete, but the observation is easier than with white light in consequence of the uniformity in the colour of the light scattered in various directions. If we begin with a blue glass, we may observe the gradually increasing obliquity of the direction of maximum polarization; and then by exchanging the blue glass for a red one, we may revert to the original condition of things, and observe the transition from perpendicularity to obliquity over again. The change in the wave-length of the light has the same effect in this respect as a change in the size of the particles, and the comparison gives curious information as to the rate of growth.

But even with homogeneous light it would be unreasonable to expect an oblique direction of perfect polarization. So long as the particles are all very small in comparison with the wave-length, there is complete polarization in the perpendicular direction; but when the size is such that obliquity sets in, the degree of obliquity will vary with the size of the particles, and the polarization will be complete only on the very unlikely condition that the size is the same for them all. It must not be forgotten, too, that a very moderate increase of dimensions may carry the particles beyond the reach of our approximations.

The fact that at this stage the polarization is a maximum, when the angle through which the light is turned *exceeds* a right angle, is the more worthy of note, as the opposite result would probably have been expected. By Brewster's law this angle in the case of regular reflection from a plate is *less* than a right angle; so that not only is the law of polarization for a very small par-

ticle different from that applicable to a plate, but the first effect of an increase of size is to augment the difference.

Sunset Colours.—The simple theory of the scattering of light by small particles suffices to explain not only the blue of the zenith, but the comparative absence of small wave-lengths from the direct solar rays, and the brilliant orange and red coloration of the setting sun and of the clouds illuminated by his rays. The hyposulphite experiment here again affords an excellent illustration. But we must not expect a simple theory to cover all the facts. It is obvious that the aerial particles are illuminated not only by the direct solar rays, but also by light dispersed from other parts of the atmosphere and from the earth's surface. On this and other accounts the coloration of the sky is highly variable. The transition from blue to orange or red at sunset is usually through green, but exceptional conditions may easily disturb the normal state of things. The brilliant sunset effects observed in Europe after the Krakatoa eruption may naturally be attributed to dust of unusual quality or quantity in the upper regions of the atmosphere.

To illustrate further the complications that arise when the particles are not infinitely small it may be mentioned that if the solution of "hypo" prepared as above be observed for a longer time it becomes more opaque owing to the growth of the sulphur particles and afterwards becomes more transparent again even though kept well stirred; and further that in this last stage it *transmits* blue more than red and consequently scatters red more than blue. This is a complete reversal of the blue-sky effect. (Keen and Porter, *Roy. Soc. Proc. A. 89,* 370, 1914.) A similar phenomenon had previously been observed by Captain Abney and by W. Ritz. Abney says in connection with certain suspensions of silver bromide in collodion: "In some cases I obtained it in such a state which, when viewed by transmitted light, appeared of a sky-blue colour inclining to green." (Abney, *Phil. Trans. Roy. Soc.* Pt. II., p. 653, 1880; W. Ritz, *Comptes Rendus 143,* 167, 1906.) This phenomenon is well known to preparers of emulsions for photographic plates.

Related to abnormalities of colour we may expect to find corresponding abnormalities in polarization. Of this nature are the neutral points, where the polarization changes character, observed by F. J. D. Arago, J. Babinet and Sir D. Brewster for an account of which reference may be made to Mascart, Traité d'Optique. (R.; A. W. Po.)

SKYE, largest island of the Inner Hebrides, Inverness-shire, Scotland. From the mainland it is separated by the Sound of Sleat, Kyle Rhea, Loch Alsh and the Inner Sound, and from the Outer Hebrides by the Minch and Little Minch. At Kyleakin, on the western end of Loch Alsh, the channel is only about ¼ m. wide, and there is a ferry. The length of the island from S.E. to N.W. is 48½ m., but its coast is deeply indented, so that no part of the interior is more than 5 m. from the sea. It has a total area of 428,966 acres. The population was 23,082 in 1841, but in 1921 only 11,031 (or 17 to the sq.m.), 1,062 of whom spoke Gaelic only and 9,201 Gaelic and English.

The chief arms of the sea are Lochs Snizort and Dunvegan in the N., Loch Bracadale in the W., Lochs Scavaig and Eishort in the S. and Loch Sligachan in the E. The jagged mass of the Cuilline (Coolins) dominates the view whether by land or sea. Their highest point is Sgurr Alasdair (3,309 ft.), and at least six other peaks exceed 3,000 ft. To the north of Loch Slapin stands the group of Red Hills of which the highest points are Ben Caillich and Ben Dearg More and near Loch Ainort rises Ben Glamaig. About 8 m. N. of Portree is the curious basaltic group of the Storr, consisting of pinnacles and towers, the most remarkable of which, "The Old Man" forms a landmark for sailors.

Most of the land is moor and hill pasture, with cultivated patches here and there, chiefly on Lochs Snizort and Bracadale, the Sound of Sleat, Kyleakin and Portree. The crofting system is still general. Turnips and potatoes are grown, but the climate is better adapted for sheep and cattle (West Highland) than for crops, and the sheep farms carry famous stocks, principally black-faced with some Cheviots. The condition of the crofters, which was pitiable in the extreme, has been improved by the Crofters' Holdings Act of 1886, and by sums spent in recent years by the Board of Agriculture. The old black huts have been replaced, in those parishes where stone is obtainable, by well-built houses. The many ejections between 1840 and 1880 and the emigration that followed was mainly responsible for the serious decline of the population. The railways to Strome Ferry, Kyle of Loch Alsh and Mallaig, by rendering markets more accessible, effected an improvement in the fisheries, which have always been a mainstay of the inhabitants. The fisheries include herring, cod, ling and salmon, and seals are not uncommon. Whiskey is distilled at Carbost and there are marble quarries.

The inhabited isles off the coast of Skye are mainly situated near the eastern shore. Of these the principal is Raasay (pop. 368). Brochel Castle, now a ruin, stands on the eastern coast. The island is 13 m. long, by about 3½ m. at its widest. Off its north-western shore lies the isle of Fladday. To the north of Raasay, separated by a narrow strait, is Rona, pop. 98 (Seal Island, from the Gaelic *ron,* a seal), 4½ m. long with a maximum breadth of 1¼ m., with a lighthouse. Scalpay, immediately south of Raasay, has a hill of 1,298 ft. The other isles are Pabbay in Broadford Bay, Ornsay in the Sound of Sleat, and Soay near Loch Scavaig.

Portree (pop. 1,628 in parish), the capital, lies at the head of a fine harbour about the middle of the eastern seaboard. Steamers run daily to and from Mallaig and Kyle of Loch Alsh, and there is, besides, other communication by steamer with Oban and other ports. There is a factory for tweeds, plaids, carpets and other woollens. The exports are principally sheep, cattle, wool, salmon and other fish, and the town is the headquarters of the fishing fleet. The name of the town was derived from the fact that James V. landed there on the occasion of his tour in the Western Highlands. The place thus became, in Gaelic, *Port-an Righ,* or the King's Harbour. It was to Portree that Flora Macdonald (1722–1790) conducted Prince Charles Edward when he escaped from Benbecula.

Among other places in Skye associated with the Young Pretender are Prince Charles's Point near Monkstadt, on the west of the peninsula of Trotternish, where he landed with Flora Macdonald, and Kingsburgh, on the eastern shore of Loch Snizort. The castle of the Macleods of Macleod, on a rocky promontory at Dunvegan, was erected in the 9th century and extended by later chieftains. The MacCrimmons, the famous race of hereditary pipers, hailed from this quarter of Skye and were attached to the Macleods of Dunvegan. At Duntulm is the ruined castle of the Macdonalds, another of the great Skye chieftains.

SKYSCRAPER: *see* ARCHITECTURE.

SLADE, FELIX (1790–1868), English art collector and patron, was born at Lambeth, London, in Aug. 1790. He collected books, engravings and glass. He died unmarried on March 29, 1868, leaving personalty to the value of £160,000. He bequeathed the bulk of his art collection to the British Museum, and £35,000 for the endowment of art professorships, to be known as Slade Professorships, at Oxford, Cambridge and University College, London. University College received the additional bequest of six art scholarships.

SLAG. A waste substance of many kinds formed during smelting operations. Thus, in the blast furnace, limestone is charged with the coke and iron-ore to form with the ash of the fuel and the gangue of the ore a lime silicate or "slag," which is run out of the furnace liquid, taking with it the sulphur. Blast furnace slags are of variable composition, the quantity of limestone used varying with the nature of the ore.

In the basic process of steel manufacture, which employs phosphoric ores, the resulting slag, rich in phosphorus (as soluble calcium phosphates) is known as "basic slag" and forms a very valuable manure. *See* IRON AND STEEL; METALLURGY; BASIC SLAG.

SLANDER: *see* LIBEL AND SLANDER.

SLANG, the current name for a particular kind of speech. At one moment a word or locution may be felt definitely as slang, but in another set of circumstances the same word or locution may not produce this impression at all. Subject to these

observations, slang may be regarded as the employment of an usual word in an unusual sense or of an unusual word in an usual sense. Thus *to beat it* would be slang, but *to depart, to go away* would be standard English. Slang is thus denied the kind of approval which is accorded to standard English. But in its origins and in its intent, slang is not merely an attempt to do violence to accepted customs. This is a by-product of its use, not the cause of it.

INVENTION OF SLANG

Among the impulses which lead to the invention of slang, the two most important seem to be the desire to secure increased vivacity and the desire to secure increased sense of intimacy in the use of language. Slang originates and flourishes best in the soil of the colloquial speech. On this level a slang word or phrase may attain a very wide currency, like *nut, bean,* and similar terms for *head,* but if such a word passes into literary use it ceases to be slang. The verb *walk,* for example, comes from Anglo-Saxon *wealcan,* meaning *to roll,* and it is not an unreasonable assumption that it comes by the way of a slang extension of the older term. This notion of locomotion by means of the legs seems to have something peculiarly appealing to the fancy of language innovators; *cf. beat it, vamoose, mosey, saunter, skidoo, slide, slip, slope,* and other metaphorical extensions. The word *pot-boiler* used for work done for a livelihood bears the marks of slang origin. But the word is not now notable or striking. The phrase *go to pot,* "go to ruin," is also of doubtful origin, and the word *pot* in this phrase may not have been the same to begin with as the word *pot,* "vessel." It suggests the modern phrase, *in the soup,* of similar meaning.

An element of humour is almost always present in slang, usually as humorous exaggeration. Thus to call a hat a *lid* is amusing because it puts a hat and a pot-lid in the same class. So when an alluring woman is called a *vamp,* from vampire. Slang is rarely or never bitter in its implied judgments. It places things in their proper places with a smile. When a male charmer is called *sheik* and the sheik's female counterpart *sheba,* this is obviously the language of a world that takes its passions lightly.

Lower Slang Forms.—On a lower rhetorical level are the forms of slang which are humorous merely because the sound of the slang words is humorous. Thus the word *skeezicks* as a disrespectful name for a man seems to mean nothing more than what is suggested by the undignified sound of the word. Some of these slang words may have an onomatopoeic colour, like *biff,* "a blow," *flummox,* "disconcert," *flabbergast,* of similar meaning, but, if so, the associations are frequently slight and remote. On a still lower rhetorical level come abbreviations employed as casual adornments of colloquial conversation, like *sec* for *second,* as *Wait a sec,* or *ever so.* Perhaps, the lowest level is reached in language mutilations like *ciricutous* for *circuitous, pictureaskew* for *picturesque, gust* for *guest.* Oaths on the other hand scarcely fall within the limits of inclusion of slang. In their origins they usually accompany a more powerful emotional experience than that which produces slang. Certain inventive geniuses, however, produce oaths which have a good deal of the playfulness and ingenuity of slang.

Slang develops most freely in groups with a strong realization of group activity and interest, and groups without this sense of unity, *e.g.,* farmers, rarely invent slang terms. The stage, prizefighting, baseball, football, and other sports are productive of an extraordinarily rich crop of slang. The language of many newspaper correspondents who write about sports is often unintelligible except to the initiated. School boys and college students also invent slang freely, and the slang of one school will often be quite different from that of another school. It is possible to have a fashionable as well as a vulgar slang. In Swift's *Complete Collection of genteel and ingenious Conversation* (1738), many of the fashionable slang terms of the day are ridiculed and condemned, and almost any novel of modern "smart" society will provide numerous illustrations. An element of secrecy sometimes enters into this use of the group language. School boys thus invent a secret language of their own.

Many of the terms that pass current in cultivated conversation have a good deal of the colour of slang. Among such terms are the words like *awful, terrible, horrid, lovely.*

Thus the common adjective of approval in Elizabethan days was *fair,* and in the 18th century it was *elegant.* Both of these terms are now archaic. A later synonym was *nice,* which in turn tends to be replaced by *wonderful.* Such counter-words are devised for the purpose of avoiding the precise definition of moments which call for nothing more than a quick and general expression. Quite meaningless expressions are often utilized in this way, for example the archaic *How would you like to be the iceman?* or *So is your old man,* or *What do you know about that?* Here is a kind of shorthand language which enables the group to express and to realize its experiences without elaborate analysis.

The Slang of Trade.—Distinction must be made between technical language and this intimate colloquial language of the group which may be called slang. Some technical words in trades and professions were in the beginning probably slang words. Thus the first tailor who called his smoothing-iron a goose, probably raised a smile and certainly started a fashion in tailoring circles.

Early Thieves' Cant.—The first extensive records of English slang occur in the cant or canting language of thieves and vagabonds in the 16th century. To a certain extent this professional cant of thieves was probably a secret language, but this could hardly have been the main motive in the invention of the cant. Thieves and vagabonds were a group with a strong sense of corporate unity and one also with certain sporting attitudes that would be highly favourable to the development of a class language.

In his treatise *On the Excellency of the English Tongue,* written about 1595, Richard Carew mentions as one of the excellences of English its ability to express the same thing in a variety of ways: "for example, when wee would be rid of one, wee vse to saye *Bee going, trudge, pack, be faring, hence, awaye, shifte,* and by circumlocution, *rather your roome than your companye, Letts see your backe, come againe when I bid you, when you are called, sent for, intreated, willed, desiered, inuited, spare vs your place, another in your steede, a shipp of salte for you, saue your credite, you are next the door, the doore is open for you, there's noe bodye holdes you, no bodie teares your sleeue,* etc." No one can doubt that some of these phrases mentioned by Carew are the equivalents of what would be called slang phrases in our day. When Chaucer wrote *There been no sterres, god wot, than a paire,* this suggests the modern equivalents *There's more than one pebble on the beach, There's more than one tin can in the alley,* etc.

American Slang.—The mixture of races and the general breaking of old associations which accompanied the first great western migrations were peculiarly favourable to the development of a highly flavoured colloquial style. And in general it may be said that the frontier in America, after the colonial period, has always been a border line of romance between reality and unreality in which slang expressions have made a vigorous growth.

Australia has slang probably for a similar reason, that the occupying of the country has been in no little degree an exhilarating and romantic adventure. (*See* Lists: *American Slang* and *Australian Slang.*

The Earliest Example.—The earliest use of the word "slang" hitherto discovered occurs in Toldervy's *History of Two Orphans,* published in 1756. A more unequivocal instance is quoted in J. C. Hotten's *Slang Dictionary* (1864) from a book entitled *Jonathan Wild's Advice to his Successor:* "Let proper Nurses be assigned to take care of these Babes of Grace (*i.e.,* young thieves). . . . The Master who teaches them should be a man well versed in the Cant Language, commonly called the Slang Patter, in which they should by all means excel." Four years later, in 1762, the word is found with a different and now obsolete meaning, in Foote's play *The Orators.* A fast young Oxford man, invited to attend a lecture on oratory, is asked, "Have you not seen the bills?" He replies, "What, about the lectures? ay, but that's all slang, I suppose." Here the word seems to be equivalent to "humbug."

In the first edition of Hugh Kelly's comedy, *The School for Wives,* there is a passage (omitted in some of the later reprints) in which one of a company of sharpers, who pretend to be for-

eigners and speak broken English, says: "There's a language called slang, that we sometimes talk in. . . . It's a little rum tongue, that we understand among von another." Francis Grose's *Dictionary of the Vulgar Tongue* (1785) has the entry, "*Slang*, the cant language."

It may be that the word is genuinely dialectal—an inheritance from the language of the Scandinavian settlers in the north of England—as shown by the coincidence of its uses with those of the modern Norwegian verb *slengja* (etymologically equivalent to the English "to sling") and related words, as given in the dictionary of Ivar Aasen. *Slengja kjeften* (literally, to sling the jaw), means to pour out abuse. The French synonym is *argot*.

The known history of European slang begins (leaving out of account the meagre references in German documents hereafter to be mentioned) about the time of the "Ballades" of François Villon in the 15th century. The French *argot* of these compositions contains much that is still obscure, but the origin of some of its words is evident enough. Facetious expressions relating to the destined end of the malefactor are prominent. *Paroir* and *montjoye* (for which latter the less ironical *monte à regret* was substituted) are nicknames for the scaffold. *Acollez*, hanged, corresponds to the English "scragged"; the synonymous *grup* seems to be an onomatopoeic formation suggestive of choking. There are some derivatives formed with the suffix *art: riflart* is a police-officer, *abrouart*, fog. A few words from foreign languages occur: *audi nos*, prayer, is the Latin *audi nos* of the litanies; *arton*, bread, is obviously Greek, and its appearance in the 15th century is somewhat hard to account for. *Moller*, to eat, may perhaps be the Latin *molere*, to grind. *Anse*, the ear, is no doubt the Latin *ansa*, handle.

In Germany the word *Rotwalsch* (the modern *Rotwelsch*, still the name for the cant of vagrants) occurs as early as the middle of the 13th century. The earliest attempt at a vocabulary of "Rotwelsch" is that of Gerold Edilbach, compiled about 1490. A second vocabulary, containing nearly the same set of words, is contained in the famous *Liber vagatorum*, first printed in 1510 in High German; versions in Low German and the dialect of the Lower Rhine appeared shortly afterwards. An edition of this work printed in 1529 has a preface by Martin Luther. The most remarkable feature of the jargon represented in these early glossaries is the large number of Hebrew words that it contains. There are some words from Italian, as *bregan*, to beg, from *pregare*, and *barlen*, to speak, from *parlare*. The language of the gipsies seems to have contributed nothing, nor are there any words from Latin or Greek. Some of the words are ordinary German words used metaphorically, like *wetterhan* (weathercock) for a hat, *zwicker* (twitcher) for the hangman, *brief* (letter) for a playing-card. Others are descriptive compounds such as *breitfuss* (broad-foot) for a duck or goose, or derivatives formed by means of the suffixes *-hart* (or *-art*) and *-ling*, as *grunhart* (from *grün*, green), a field, *glathart* (from *glatt*, smooth), a table, *fluckart* (from *flug*, flight), a bird, *funckart* (from *funke*, spark), fire, *flossart* (from *floss*, stream), water, *flossling*, a fish, *lüssling* (from *lüssnen*, to listen), the ear. It is noteworthy that modern Dutch thieves' cant, as presented in the dictionary of I. Teirlinck, is closely similar in its principles of formation, and in many of its actual words, to that of the early German vocabularies.

The earliest English "cant" or "Pedlars' French," as exhibited in R. Copland's *The Hye Waye to the Spyttel House* (1517), John Awdeley's *Fraternitye of Vacabondes* (1561), Thomas Harman's *Caueat for Commen Cursetours* (1567) and various later writers, bears a close resemblance in its general character to the German *Rotwelsch* of the *Liber vagatorum*, the most noteworthy point of difference being the absence of Hebrew words.

BIBLIOGRAPHY.—English: Most of the authorities for the early history of English vagrant slang are reprinted in vol. ix. of the Extra Series of the Early English Text Society, edited by E. Viles and F. J. Furnivall (1869), which contains John Awdeley's *The Fraternitye of Vacabondes* (from the edition of 1575), Thomas Harman's *Caueat for Commen Cursetours* (1567–73), and *The Groundwork of Connycatching* (anonymous, 1592), besides extracts from other early works which furnish glossaries. *The Dictionary of the Canting Crew*, by B. E. (no date, but printed at the end of the 17th century; photographic reprint by J. S. Farmer), is valuable as containing the earliest known record of many words still in use; while mainly treating of thieves' and vagrants' language, it includes much that belongs to slang in the wider sense. Among the many later works, only the following need be mentioned here: Francis Grose's *Classical Dictionary of the Vulgar Tongue* (3rd ed. 1796); *The Slang Dictionary*, anonymous but understood to be by the publisher, J. C. Hotten (new ed. 1874), a work of considerable merit, with an excellent bibliography; *A Dictionary of Slang, Jargon and Cant*, by A. Barrere and C. G. Leland (1889); and *Slang and its Analogues* by J. S. Farmer and W. E. Henley (1890–1904), which surpasses all similar works in extent of vocabulary and abundance of illustrative matter, though the dates and even the text of the quotations are often inaccurate. A supplement to Farmer and Henley's *Slang and its Analogues* is J. Redding Ware's *Passing English of the Victorian Era* (1909). For the slang of public schools see *The Winchester Word-book*, by R. G. K. Wrench (1901), and *The Eton Glossary*, by C. R. Stone (1902). For a collection of American college slang words, *see* H. J. Savage's *College Slang Words*, in Dialect Notes V. 139–148 (1922), and for a more extended bibliography in general, *see* Kennedy's *Bibliography of Writings on the English Language*, pp. 419–435 (1927).

French: The earliest systematic treatment of *argot* is found in *La Vie généreuse des Mattois, Gueux Bohémiens et Cagoux*, by Pechon de Ruby (a pseudonym), which went through several editions in the early part of the 17th century and has been reprinted in 1831 and 1868. The slang of the 15th century is discussed in *Le Jargon au quinzième siècle*, by Auguste Vitu (1883), which includes an edition of the *Ballades* of Villon; in *Le Jargon et jobelin de F. Villon*, by Lucien Schöne (1887), and in *L'Argot ancien* (1907), and in *Les Sources de l'Argot ancien* (1912) by L. Sainéan. Francisque Michel's *Études de philologie comparée sur l'argot* (1856) is important for its rich collection of material and its copious references to sources. Later works deserving attention are *Dictionnaire de la langue verte*, by Alfred Delvau (2nd ed. 1867), and *Dictionnaire de l'argot*, by Lorédan Larchey (1889). For modern slang, taken in a very comprehensive sense, the chief authority is Lucien Rigaud, *Dictionnaire de l'argot moderne* (1881). For the special slang of printers, *see* Eugène Boutmy, *Dictionnaire de l'argot des typographes* (1883). A collection of slang terms that gained currency during the Great War is contained in L. Sainéan's *L'Argot des Tranchées* (1915).

German: An admirable collection of the original documents for the history of thieves' and vagrant slang from the earliest period has been published by F. Kluge, under the title *Rotwelsch* (1901). An earlier book of great importance is by Avé-Lallemant, *Das deutsche Gaunertum* (1858). For modern popular slang *see* A. Genthe, *Deutsches Slang* (1892). University slang is ably treated in *Deutsche Studentensprache*, by F. Kluge (1895). (H. BR.; G. P. K.)

BRITISH SLANG

The following list gives well-established slang of a general type dating from the eighteenth century.

Abram-men, beggars pretending madness to palliate their thefts.
Adam-tiler, a pickpocket's ally.
Alsatia, White Friars, an old district of London.
Ambrol, navy word for admiral.
Babbler, a chatterbox.
Baggage, a worthless woman.
Balderdash, (a) unpleasant mixtures of wine, ale, etc.; (b) rubbish, trash, nonsense.
Bandy, crooked; as, *bandy*-legged.
Banter, ridicule.
Barnacle, a good job, easily got.
Bawbee, a halfpenny.
Bean, head.
Beldam, a scolding old woman.
Biff, a blow; *to biff*, to strike.
Bilk, to cheat.
Blab, to divulge secrets.
Blockhead, a silly fellow; fool.
Bob, a shilling.
Bobby-dazzler, anything flashing or brightly coloured.
Bog-landers, Irishmen.
Bone, to steal.
Booze, liquor.
Boss, (a) master; chief; (b) *to boss*, mess up something; *a boss shot*, a futile effort.
Bounce, bragging, boasting.
Brass, (a) impudence; "brazen-faced"; (b) money.
Browbeat, to bully.
Cackle, to tell a secret.
Cant, hypocrisy.
Carrots, a red-haired person.
Char, a task; work of any kind.
Chink, money.
Chit, a child.
Chop, to change; barter.
Clack, a woman's tongue.
Claret, blood; as, "tap his claret": make one's nose bleed.
Clink, gaol; a cold cell.
Clodhopper, a ploughman.
Clout, a handkerchief.
Cocksure, very certain.
Cod, *to cod*, to deceive.
Cold tea, brandy.
Corker, very good.
Cosset, to spoil with affection.
Cove, a man; fellow.
Coxcomb, a fool.
Crack, to boast; glorify.
Cully, a man; fop; rogue.
Cut out for, suited to.
Dab, an expert.
Dace, twopence.
Dag, a gun.
Darbies, handcuffs.
Dive, to pick a pocket.
Dowdy, coarse or ill-favoured.
Drub, to beat.
Dubber, a lock-picker.
Duds, clothes.
Dunderhead, a stupid fellow.
Egg on, to urge.
Famms, hands.
Fambles, hands.
Fib, (a) to beat; (b) a lie.
File, to rob.

Fin, hand.
Fleece, rob or plunder.
Flyers, shoes.
Fob, (a) a cheat, *to fob off,* to cheat; (b) a small pocket.
Fop, a fool; dandy.
Freshman, a novice in a university.
Gad, to go about aimlessly; idle.
Game, gamie, lame.
Giglamps, spectacles.
Glaziers, eyes.
Gob, the mouth.
Grinders, teeth.
Half seas over, almost drunk.
Heave, to rob.
Hedge, to make secure a desperate bet.
Hick, a foolish, easy person.
Hob, a plain country fellow.
Hodge, a country clown.
Hog, a shilling.
Hoof it, to walk.
Huckster, a sharp fellow.
Hussy, a reproach for a woman.
Jabber, useless chatter.
Jackanapes, a young rascal.
Jade, a lazy woman.
Jail-birds, prisoners.
Jolly, to tease.
Josh, to tease.
Kid, to delude; deceive.
Lace, to beat; strike.
Lag, a prisoner.
Lid, a hat.
Lift, to steal.
Loon, a fool or a knave.
Lubber, a heavy, dull fellow.
Lugs, the ears.
Mab, a slattern.
Minx, a forward girl or woman.
Moppet, a pretty, saucy girl.
Mumchance, one who sits mute.
Nab, (a) a hat, cap, or a head; (b) to take.
Nark, a police spy.
Neb, the bill of a bird.
Nincompoop, a fool.
Nob, the head.
Nub, the neck.
Numskull, a foolish person.
Oaf, a fool.
Ogles, eyes.
Old Harry, the Devil.
Old Nick, the Devil.
Pad, a highwayman.
Peeper, a looking-glass.
Peepers, eyes.
Phiz, face (from physiognomy).
Pickled, drunk.
Pig, sixpence.
Pinch, to steal.
Pins, legs.
Poke, a bag or sack.
Ponk, to stink; also, a bad smell.
Prig, (a) a thief; (b) to steal.
Puke, to be sick; vomit.
Quack, an unqualified doctor.
Rant, to talk big.
Rap, to exchange.
Reach-me-downs, a suit of ready-made ill-fitting clothes.
Ready, ready money; cash.
Rhino, ready money.
Ripper, something excellent.
Rub, to run away.
Rum, queer; strange.
Runt, a short, insignificant man.
Sack, (a) pocket; (b) *to get the sack,* to lose one's job.
Sawny, a fool.
Scab, a scoundrel.
Scout, a watch.
Shark, a sharper; trickster.
Sharp-set, very hungry.
Shaver, a young boy.
Shop, a prison.
Sice, sixpence.
Simkin or simp, a fool.
Sly-boots, a seemingly silly, but subtle, fellow.
Snaffle, to appropriate.
Sock, (a) a pocket; (b) to beat.
Split, inform against someone.
Sponge, *To sponge on someone,* to live or drink at another's cost.
Stumps, legs.
Swag, booty; plunder.
Swap, to change; barter.
Tanner, a sixpence.
Tar, a sailor.
Tomboy, a boyish girl.
Tippler, a drunkard.
Tope, to drink.
Truck, change or barter.
Tube, deep level railway.
Wag, a joking, humorous fellow.
Zany, an idiot, fool, or jester.

See *A New Dictionary of the Terms, ancient and modern, of the Canting Crew* (1690); Raymond Postgate, *Murder, Piracy and Treason* (Appendix and Bibl.) (1926).

British War Slang.—The slang which became current during the World War was characterized by novelty:

Anzac, from *A*ustralian and *N*ew *Z*ealand *A*uxiliary (or *A*rmy) *C*orps.
Aussie, an Australian soldier.
Big Bertha, the German gun that bombarded Paris from a distance of 76 miles.
Billy, a cooking tin or pannikin.
Blighty, England (from Hindustani, *bilati,* homeland).
Blimp, a small, non-rigid, streamline, dirigible airship (perhaps from limp balloon).
Brass hat, an officer of the general headquarters staff.
Bully, pressed beef.
Canuck, a Canadian soldier.
C.B., confined to barracks.
Chatty, verminous.
Coal-box, trench-mortar discharge.
Cold feet, funk; nervousness.
Conchy, conscientious objector.
Cushy, a safe job,
Cuthbert, a conscientious objector.
Daisy cutter, an explosive shell.
Doughboy, an American soldier.
Dug-out, a trench cave.
Dum-dum, a soft-nosed bullet.
Fag, a cigarette.
Fritzy, a German soldier.
Humdinger, a swift, good, splendid, fine something or other (borrowed slang).
Iron rations, emergency rations.
Jerry, enemy soldiers.
Joy-ride, "jumping" a ration-lorry, or an aeroplane, without official sanction.
Joy-stick, the altitude control of an aeroplane.
Napoo, no more (French).
No bon, no good (French).
Old Contemptibles, the 1914 British forces.
Packet, to get a, to be wounded.
Pigsticker, bayonet.
Pill-box, small blockhouse.
Rooty, bread (from Hindustani, *roti*) (Indian army slang)
Sausage, observation balloon
Swing the lead, to malinger.
T.B.D., torpedo-boat destroyer
V.A.D., a nurse of the Voluntary Aid Detachment.
Waacs, members of the *W*omen's *A*uxiliary *A*rmy *C*orps.
Whizz bang, a high-explosive shell.
Wrens, members of the Women's Royal Naval Service.

AMERICAN SLANG

All in, exhausted physically
All set, in readiness to begin
Applesauce, insincere talk; "bunk"
Attaboy (that's the boy) fine!
Back number, superannuated
Back-talk, impertinence
Balled up, confused; mixed up
Banana oil (ejac.) nonsense!
Bat, a spree
Bawl out, to rebuke sharply
Bean, head
Beanery, cheap eating-place
Beat it, get out; make a rapid exit
Beef (to), to complain
Beezer, head
Berry, dollar
Big boy, a term of admiration
Big cheese, the "boss" or chief
Blah, nonsense; piffle
Blink (on the), out of repair
Block, head
Blooey (to go), to explode
Blow in, to spend with great lavishness
Blues, to be woebegone
Blurb, publishers' advertisement
Bo (abbr. of hobo, *q.v.*): mate
Boloney, nonsense
Bone, dollar
Bonehead, a fool
Boob, a stupid person
Boost, a recommendation
Bootlegger, dealer in prohibited liquor
Boy-friend, fiancé, or close friend (used by opposite sex only)
Bottom dollar, last dollar
Break even, to come out of a game neither winner nor loser
Break (to make a) *faux pas*
Breaks (to get the), to be in luck
Bring home the bacon, come home victorious in any effort
Broke, penniless
Buck, dollar
Buck (pass the), to shift a responsibility to another
Buddy, close companion
Bull, police
Bulldoze, to intimidate; to bully
Bull (throwing the), boasting
Bum, vagrant
Bun, head
Bunk, nonsense; rubbish
Busted, without funds
Butt in, interfere
Cagey, wary of giving confidence
Call down (to), to correct
Call-down, a rebuke
Can, to discharge; to throw out
Canned music, that which is played by mechanical means.
Can you beat it? (equivalent to "Did you ever!")
Case-note, dollar
Caught with the goods, caught in the act
Chase yourself, get out
Cheap skate, a poor spender
Cheese it, run; look out
Chesty, puffed up; vain
Chicken feed, small money
Chow, food; a meal
Chump, a simpleton
Cinch (also *lead-pipe cinch,* and hence shortened to "a pipe," *q.v.*), a sinecure
Classy, handsome; stylish; chic
Cop, policeman
Crab, to spoil (as to *crab an act*)
Crack, a shot (figuratively, as *a dirty crack*—a mean hit)
Crash, severe blow; vb., to deal a heavy blow
Crook, thief
Crust, presumption
Cuckoo, crazy
Cute, petite; amusing; attractive.
Date, an appointment; *heavy date* an extra important appointment
Dead-beat, worthless fellow
Dead above the ears, brainless
Doggy, stylish
Dome, head
Dope, the facts in a situation; also drugs, as cocaine.
Dough, money
Down and out, at the end of one's resources
Double-cross, to betray.
Drag, influence.
Dry, opposed to liquor
Dub, a stupid person, a silly
Duck out, to escape
Dumbbell, a fool
Eats, food; a meal
Easy, gullible; easily duped
Edge, to have the; to have the advantage
Fade out, to disappear; take quick leave
Fake, an imposture
Fall down on, to fail at
Fall for, to be infatuated with
Fan, fanatic, ardent admirer
Fat-head, brainless person, a fool
Fire, to dismiss from a position
Fifty-fifty, divide equally
Fixin's, trimmings; extras, as at a meal
Fizzle, a failure
Flapper, young girl
Flat tire, a deflated scheme
Flivver, to pull a, to blunder
Flop, a failure
Four-flusher, one who promises without performing
Frame, to, to fabricate evidence
Frame-up, a trumped-up piece of evidence
Fresh, impertinent
Fritz, on the, out of repair
Frost, a failure
Gab, impudent talk
Gaff, chaffing; *standing the gaff*—standing the pace
Get away with, to carry through an action undetected
Get down to brass tacks, deal with the bare facts
Get the gate, be discharged
Get one's goat, try one's patience
Get one's hooks on, get hold of
Get the bulge, gain an advantage
Get wise to, to become aware of
Gink, chap
Girl-friend, fiancée or close friend
Give-away (usually dead give-away), betrayal
Give a ring, to telephone
Go fish!, Go along!
Go, to make a, to succeed
Go-getter, a practical, energetic person
Go over big, to, to succeed
Going some, doing well
Gold-digger, a woman who habitually wheedles money, gifts, etc., from gullible males
Good-night!, This is the end!
Grand, a thousand dollars
Gravy, profit
Grouch, a sour, peevish person
Grub, food
Guff, nonsense

Gush, to be effusive
Gyp, to cheat
Guy, fellow, as, a *regular guy*
Hand-picked, carefully selected
Hang, to get the, to understand
Hard-boiled, callous
Has-been, discarded favourite
Hash-house, cheap eating-place
Heebey-Jeebies, the nerves
Hick, a country bumpkin
Highbrow, intellectual (n. or adj.)
High-hat, supercilious
High stepper, one who leads a gay or fast life
Hike, a long walk
Hitch, ride; sometimes stolen, on a passing vehicle
Hitch-hike, long-distance walk interspersed with begged or proffered rides in passing vehicles
Hobo, tramp, often shortened to "bo"
Hock, to pawn; *in hock*—in pawn
Hold on, Wait a minute!
Hooey, bunk, falseness
Horn in, to intrude
Hot air, exaggerated statements
Hot dog, excl. of approval
Hot stuff, good work
Hunch, presentiment
I'll say, I agree
I'll tell the world, I'll say as much
Inside dope, confidential information
Iron-man, silver dollar
Jack, money
Jack up, to remind, to jog
Jag (to have a jag on), drunken spree; to be drunk
Jazz-baby, usually a young woman who is fond of jazz
Jazz-hound, a dance fiend
Jazz up, to make lively
Jinx, hoodoo
Joint, an establishment, as a dance-hall, restaurant, etc.
Jolly, to keep another person cheerful by saying what he wishes to hear
Josh, to tease
Junk, anything poor in quality
Kale, money
Keep your shirt on, keep cool
Kick, to complain
Kid (vb.), to tease
Knob, head
Knock, condemn or criticize
Lemon, undesirable person
Let down, to cease relations without warning
Let up, to cease
Limit, last endurable stage of any situation, as "Isn't that the limit?"
Line, to get a, to gather information about
Lit, inebriated
Live wire, energetic person
Lounge-lizard, man who haunts tearooms for flirtation
Low-brow, uncultured
Low-down (n.), all the important information
Make, on the, on the road to a successful career
Make a getaway, escape
Make the grade, accomplish the task in hand (origin of a motor-car on a hill)
Main squeeze, the chief
Mazuma, money
Melon, financial term, signifies distribution of unusual dividend
Miffed, piqued
Miss out, to let an opportunity slip by
Mixer, one who meets all types of persons easily
Monkey-business, foolish trifling
Monkey-shines, buffoonery
Moonshine, privately distilled whiskey
Nail, to arrest; to catch at the psychological moment
Neck, to embrace
Nerve, impudent cheek
Nifty, stylish; chic
Nix! No!
N.G., no good
Nothing doing, no chance whatever
Number, to get one's, to see through another's motives
Nut, idiot
Nutty, very enthusiastic about
Off one's base } badly mistaken
Off one's trolley }
O.K., approved
Old stuff, out of date
Once-over (also called the double-O), intense scrutiny
Outfit, group of people, especially a business organization
Pan out, to result
Pass out, lose consciousness
Pass up, to let slip
Peach, a pretty girl
Peeved, annoyed
Pep, energy, vim
Petting, amorous fondling
Petting party, social gathering with amorous fondling
Phoney, bogus; not genuine
Pickled, intoxicated
Pie-eyed, intoxicated
Piffled, half intoxicated
Pinch, arrest
Pipe, a simple task
Pipe (vb.), look at! (derisive)
Plant, factory
Played out, exhausted
Poppycock, nonsense
Poor fish, an ineffective person
Pronto, immediately
Pull, influence
Pull off, to initiate and carry through a plan
Punch, vigour
Punk, utterly worthless
Put across, to accomplish by one's own effort
Put the skids under one, get rid of one
Put wise, to acquaint with the facts in a situation
Put over, to accomplish
Put-up job, a conspiracy
Queen, a lovely girl
Queer, to, to compromise, damage
Racketeer, a gangster who extracts money for protection
Razz, to heckle
Razz (abbr. of raspberry), to get the, to be made fun of
Regular fellow (or guy), agreeable or "good" person
Ritzy, stylish
Rooked, cheated
Root, to shout for
Rooter, ardent defender
Rotten, worthless
Rough, unfair
Rough up, to treat harshly
Roughneck, rowdy
Rubberneck, a sightseer
Rube, a rustic
Rum-hound, one who drinks to excess
Run into the ground, to overdo
Rustle, to gather; to go in quest of, as *to rustle food*
Sap, a brainless person
Sand, grit; courage
Sec, second
Shake a leg, move on
Shine (take a shine to), to become suddenly fond of
Shoestring, on a, with very little capital
Shoot! Go ahead!
Sidestep, to evade
Simoleon, dollar
Simp, simpleton
Sit in, join with
Size up, to make a rapid estimate of
Skin, cheat (n. and vb.)
Skin-game, fraudulent enterprise
Skirt, woman, girl
Slob, an untidy, careless person
Slop, sentiment
Slush, sentiment
Small-time stuff, unimportant
Snap, sinecure
Snap out of it (or into it), to shift rapidly to or from some position or procedure
Snooty, critical
Sob sister, a woman reporter who writes over-sentimentally
Sock, a severe blow
Soft snap, a sinecure
Solid ivory, stupid, unintelligent
Soup and fish, formal dinner dress
Souse, an habitual drinker
Sparkler, diamond
Speakeasy, place where liquor is sold and drunk illegally
Spondulix, money
Squarehead, a Swede
Squeal, to betray an accomplice
Stand for, endure; tolerate
Stand-up, failure to meet an appointment
Steady, fiancé (both sexes)
Steep, exorbitant
Step on it, hurry up
Step out, go out on pleasure
Stewed, intoxicated
Strapped, without money; "broke"
String, to jolly
String to it, with a; under conditions or limitations (usually something is given "with a string to it")
Stuck with, foisted with something undesirable
Stuck on, infatuated by
Stuff, the (as "That's the stuff—that's the real thing"), the real thing
Stung, taken in; cheated
Stunt, trick, usually acrobatic
Sugar daddy, a rich elderly man who lavishes money and gifts on young women (also called sugar papa)
Swag, loot
Swat, to hit, also *a blow*
Swell, superfine; as a swell time, a swell girl, a swell idea.
Talk turkey, to speak frankly
Tear, a wild spree
Tell it to Sweeney, same as *Tell it to the Marines!* (an expression of incredulity)
Tickle the ivories, play the piano
Tip, a hint
Tip off, to inform
Tony, aristocratic
Up and coming, promising
Up on one's toes, alert, eager
Up to snuff, competent, up to expectation
Velvet, clear profit
Walk-over, an easy task
Wet, opponent of prohibition
Whale (as *a whale of a show*); a splendid specimen
Wire-puller, a person who contrives for his own ends
Whiz, a wonder
Wow, a great success
Wheels (to have), to be mentally unsound
Wild about, very fond of; infatuated by
Willies, the, an attack of "nerves"
Wise-crack, smart remark
Yank, to snatch, to drag away
Yegg, a thief
Yellow, cowardly
Yellow streak, a vein of cowardice

AUSTRALIAN SLANG

Abo, aboriginal, a journalese term.
Aussie, an Australian citizen and, during the World War, especially, an Australian soldier.
Baal, a term of dislike (native word).
Back-blocks, inland settlements and towns.
Bananalander, a Queensland citizen.
Billabong, a small off-shoot from a river which in wet weather rejoins the main stream lower down.
Billy or Billy-Can, a tin container used for cooking purposes.
Blackfellow, an Australian aborigine.
Bluey, a swagman's blanket.
Bonzer, something good—satisfactory.
Bosker, adjective of Bonzer.
Boss-Cockie, a small farmer employing labour, but also working himself.
Brumby, a wild horse.
Buckjumper, a refractory horse.
Budgeree, good or palatable (native word).
Bush, woods, forest.
Bushranger, an armed highwayman.
Chow, a Chinese.
Coo-ee, the Australian hail (native word).
Cornstalk, a citizen of New South Wales.
Corroboree, a noise, uproar (native word).
Cossie, a swimming costume.
Creek, a stream, brook.
Damper, a large scone.
Digger, friend, comrade,
Diggings, a gold-mining centre.
Dilly-bag, a small domestic bag.
Dingo, a native dog.
Dinkum, true; genuine.
Fossicker, one who looks for gold in rocky crevices.
Gazob, a fool.
Gin, a native woman.
Groper, a West Australian.
Gully, a rugged valley.
Gum-sucker, a citizen of Victoria.
Hard-hitter, a bowler hat, a derby.
Hide, impudence, cheek.
Humpy, a hut.
Jackaroo, a young man of good position who joins a station to learn sheep and cattle farming.
Joey, a young kangaroo.

John, a policeman.
Jumbuck, sheep.
Kid-stakes, foolery.
Knock-down, an introduction.
Larrikin, a hooligan.
Lolly, a sweetmeat.
Lubra, an aboriginal woman.
Mauldy, left-handed.
Maorilander, a New Zealander.
Never-never, remote unsettled districts.
Nuggety, short and sturdy.
Orchardist, a fruit-grower.
Outback, districts far inland from the coast.
Outer, a betting ground overlooking a racecourse.
Outlaw, a savage horse.
Overlander, a drover taking cattle from one state to another.
Poddy, a land-fed calf.
Pointer, an opportunist who takes mean advantages.
Possie, a job.
Push, a band of larrikins.
Ready up, a conspiracy.
Ringer, the quickest shearer of a gang.
Rouse-about, an odd-job man in a shearing shed.
Run, a track of grazing land.
Scrub, a stretch of bush undergrowth.
Shake-down, a makeshift bed.
Shanghai, a catapult.
Shanty, (a) a crude hut; (b) a "sly-grog" shop in the bush. A "blind tiger" or "speak-easy."
Shelf, an informer.
Shicker, intoxicants, "booze."
Shielah, a girl.
Springer, a cow approaching the milking period.
Squirt, a revolver.
Squatter, a "pastoralist"; an owner of a sheep- or cattle-run.
Station, a cattle-run—sheep-run.
Sticky-beak, an inquisitive person.
Stockman, a man in charge of cattle on a run.
Sundowner, an outback Swagman; *see* SWAGGIE.
Swag, a bundle containing tent, blanket, etc.
Swaggie, a sundowner; a wanderer with his kit, tramping from place to place.
Take-down, a thief—a cheat.
Tipslinger, a racecourse tipster.
To go bung, to collapse financially (as a bank).
To shake, to steal.
To sling off, to poke fun at.
To sool, to urge on, as dogs.
Too right, a term of agreement
Tray-bit, a threepenny bit.
Trooper, a mounted policeman.
Tucker, food.
Waddy, a heavy stick or club.
Woop-woop, a New South Wales word for country districts.
Wowser, a straight-laced person.
Yabber, to talk (native word).
Yacker, work (native word).
Yarraman, a horse (native word).
Ziff, a beard.

See Jice Doone, *Timely Tips for New Australians*, London, n.d.

SLATE, in geology, a fissile, fine-grained argillaceous rock which cleaves or splits readily into thin slabs having great tensile strength and durability. Some other rocks that occur in thin beds are improperly called slate, because they can be used for roofing and similar purposes. Stonefield slate, a thinly bedded limestone occurring near Oxford, is one of the best known. True slates do not, as a rule, split along the bedding, but along planes of cleavage, which may intersect the bedding at any angle, usually, in the case of good roofing slates, at high angles. The original material was a fine clay, sometimes with sand or volcanic dust, and the bedding of the sediment as originally laid down may be indicated by alternating bands, differing in colour or in lithological character, sometimes to be seen on the cleavage faces of the slates. Cleavage is a superinduced structure, the result of pressure acting on the rock at some time when it was deeply buried beneath the earth's surface. On this account slates are found chiefly among the rocks of the older geological systems, although some occur in regions where comparatively recent rocks have been folded and compressed as a result of mountain building movements in the earth's crust.

In thin sections for microscopical examination, slates show much colourless mica in small, irregular scales, which in the best average about two thousand to the inch in breadth, and six thousand to the inch in thickness. Green chlorite in flakes is also usually abundant, the principal other ingredient being quartz, in minute lens-shaped grains. In colour, slates may be black, blue, purple, red, green or grey; dark slates usually owe their colour to carbonaceous material or to finely divided sulphide of iron, reddish and purple varieties to the presence of oxide of iron in the form of haematite, and green varieties to the presence of much chlorite. Slates are widely used for roofing purposes, for not only are they easily prepared and fixed, but they are weatherproof and durable.

North Wales provides most of the slate used in the British Isles, but slate of economic importance also occurs in North Devon, the Lake District, Scotland (Ballachulish) and Ireland (Kilkenny). There are also important quarries in France (the Ardennes), Bohemia, Germany (near Coblenz) and in the United States; it is sometimes obtained from open quarries, and sometimes from underground workings or mines.

The material is sometimes removed by means of "channelling machines," which make cuts in the face of the rock allowing a block to be wedged off; or, when blasting is resorted to, advantage is taken of the joints and other planes of weakness in the rock. The masses, dislodged by whatever means had been adopted, are divided into blocks small enough to be sent to the sheds where they are split and dressed.

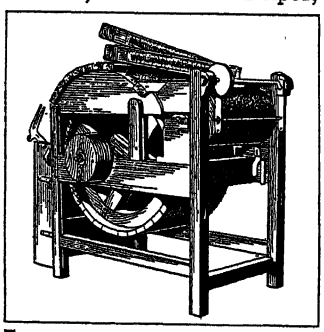
In "making" slates, the splitter takes blocks about 3 inches thick, and a chisel, placed in a certain position against the edge of the block is lightly tapped with a mallet; a crack appears in the direction of cleavage, and slight leverage with the chisel serves to split the block into two pieces with smooth and even surfaces. This is repeated until the original block is converted into 16 or 18 separate "slates," the thickness of which depends upon many circumstances, such as quality of rock, size required, and purpose for which it is to be used, the average thickness of a roofing tile of the best kinds of slate being about $\frac{1}{6}$ in. The slates are afterwards trimmed to size, either by hand, in which case they are cut between a fixed sharp edge and a movable knife acting on the principle of a printer's guillotine, or by means of machine-driven rotating knives.

A detailed bibliography of works relating to the origin, distribution and utilization of slate will be found in *The Slates of Wales* (National Museum of Wales, 1927). (F. J. N.)

SLATE CLUB. A society of persons who pay periodically small sums with the purpose of accumulating a fund which is shared out at a special time—in England, usually Christmas. The funds are not invested but merely retained by the secretary; the aim is thus "automatic saving." (*See* FRIENDLY SOCIETIES.)

SLATER, JOHN FOX (1815–1884), American philanthropist, son of John Slater (Samuel Slater's brother and partner), was born in Slatersville (R.I.), March 4, 1815. At 17 he entered his father's woollen mill in Hopeville (Conn.), of which he took charge in 1836. He helped to endow the Norwich Free academy. He died in Norwich (Conn.), May 7, 1884. In 1882 he had made over to a board of 10 trustees, incorporated in New York State, $1,000,000 for "the uplifting of the lately emancipated population of the Southern States, and their posterity, by conferring on them the benefits of Christian education." Its largest beneficiaries have been the Hampton Normal and Agricultural institute, Hampton (Va.), the Tuskegee Normal and Industrial institute of Tuskegee (Ala.), Spelman seminary in Atlanta (Ga.), Claflin university in Orangeburg (S.C.), and Fisk university, in Nashville (Tenn.). At Winston-Salem (N.C.), is the Slater State Normal and Industrial school, founded in 1892. Other State normal schools for negroes, as well as the school boards of certain Southern cities, have received assistance from the fund.

SLATER, SAMUEL (1768–1835), American textile manufacturer, was born in Belper, Derbyshire, England, on June 9, 1768. In 1783 he was apprenticed to a partner of Richard Arkwright in spinning cotton. Learning that the Pennsylvania legislature had granted £100 in 1789 to the inventor of a power carding machine, he removed to the United States in that year, but was unable because of British laws to bring with him drawings of cotton-spinning machinery. In Jan. 1790 he went to Pawtucket (R.I.), where he entered into a partnership with William Almy and designed from memory machines for cotton-spinning, and turned out some yarn. In 1799 he established in his mills one of the first Sunday schools in America.



THE CARDING MACHINE BUILT AFTER AN ENGLISH DESIGN BY SAMUEL SLATER, FROM THE ORIGINAL IN THE U.S. NAT. MUSEUM

In 1801 he built a factory in Rehoboth (Mass.), and with his brother John established in 1806 the manufacturing village of Slatersville (R.I.). He began the manufacture of woollen cloth in 1815–16 at Oxford, now Webster (Mass.), where he had built cotton mills in 1812. In his later years he was interested in other

textile mills, and in iron foundries in Rhode Island. He died at Webster (Mass.), April 21, 1835. He has been called the "father of American manufactures."

See G. S. White, *Memoir of Samuel Slater,* 2nd ed. (1846).

SLATIN, SIR RUDOLF CARL VON (1857–), Anglo-Austrian soldier and administrator in the Sudan, was born on June 27, 1857, at Ober St. Veit near Vienna. At the age of seventeen he made his first journey to the Sudan, reaching Khartum by the Nile route in October 1875 in company with Theodor von Heuglin (*q.v.*). Thence he went through Kordofan to Dar Nuba, exploring the mountains of that region. He returned to Khartum in consequence of a revolt of the Arabs against the Egyptian government. There Slatin met Dr. Emin (Emin Pasha) and with him purposed visiting Gordon at Lado, Gordon at that time being governor of the equatorial provinces. Slatin, however, was obliged to return to Austria without accomplishing his desire, but Emin went to Lado, and at Slatin's request recommended the young traveller to Gordon for employment in the Sudan. In 1878, while Slatin was serving as a lieutenant in the crown prince Rudolf's regiment in the Bosnian campaign he received a letter from Gordon inviting him to the Sudan, of which country Gordon had become governor-general. Slatin arrived at Khartum in January 1879. After a brief period during which he was financial inspector, Slatin was appointed mudir (governor) of Dara, the south-western part of Darfur, a post he held until early in 1881, when he was promoted governor-general of Darfur and given the rank of bey. While administering Dara, Slatin conducted a successful campaign against one of the Darfur princes in revolt, and as governor of Darfur he endeavoured to remedy many abuses. He had soon to meet the rising power of the mahdi Mohammed Ahmed (*q.v.*). Early in 1882 the Arabs in southern Darfur were in revolt. With insufficient resources and no succour from Khartum, Slatin gallantly defended his province. Though victorious in several engagements he lost ground. His followers attributing his non-success to the fact that he was a Christian, Slatin nominally adopted Islam. But all hope of maintaining Egyptian authority vanished with the news of the destruction of Hicks Pasha's army, and in December 1883 Slatin surrendered, refusing to make any further sacrifice of life in a hopeless cause. In the camp of the mahdi an attempt was made to use him to induce Gordon to surrender. This failing, Slatin was placed in chains, and on the morning of Jan. 26, 1885, an hour or two after the fall of Khartum, the head of Gordon was brought to the camp and shown to the captive. Slatin was kept at Omdurman by the khalifa, being treated alternately with savage cruelty and comparative indulgence. At length, after over eleven years' captivity, he was enabled, through the instrumentality of Sir Reginald (then Major) Wingate of the Egyptian Intelligence Department, to escape, reaching Egypt in March 1895.

In a remarkable book, *Fire and Sword in the Sudan,* written in the same year and issued in English and German in 1896, Slatin gave not only, as stated in the sub-title, "a personal narrative of fighting and serving the dervishes" but a connected account of the Sudan under the rule of the khalifa. Raised to the rank of pasha by the khedive, Slatin received from Queen Victoria the C.B. He served as staff officer in the campaigns of 1897–98 which ended in the capture of Omdurman and was made a K.C.M.G. and in 1906 was ennobled by the emperor of Austria. He was inspector-general of the Sudan from 1900 to the outbreak of the World War. His mastery of Arabic and his profound knowledge of the land and peoples proved invaluable in the work of reconstruction. In 1907 he was made an honorary major-general in the British army, and in 1912 was made G.C.V.O. During the World War he presided over the Austrian Red Cross for the Aid of Prisoners of War.

SLATING: *see* ROOFS.

SLATINGTON, a borough of Pennsylvania, 16 m. N.W. of Allentown. Pop. (1920), 4,014; and in 1930, 4,134. There are some 20 slate quarries in the neighbourhood, and the borough manufactures roofing and electrical slates and blackboards, and has knitting mills, silk mills, rug and garment factories. Slatington was settled about 1737 and incorporated in 1864.

SLAUGHTER-HOUSE or ABATTOIR. Slaughter-houses are of two kinds, those which belong to individual butchers (private) and those which belong to public authorities (public). Private slaughter-houses in existence in England before the passing of the Public Health Act 1875 were in most instances established without licence by the local authority, but after 1890 urban authorities adopting Part III. of the Public Health (Amendment) Act of that year could license for limited periods of not less than one year all slaughter-houses coming into existence after such adoption. In London, slaughter-houses have been licensed since 1855. In countries where the inspection of meat is compulsory, private slaughter-houses tend to be superseded by public abattoirs.

Public slaughter-houses are of great antiquity and owe their beginnings to Roman civilization. They existed in many large towns of Germany in mediaeval times under the name of *Kuttelhöfe,* some of which continued to exist within recent years. Their use, however, was not obligatory but shortly after the middle of the 19th century the prevalence of trichinosis compelled a return to the compulsory use of them (Schwarz, *Bau, Einrichtung und Betrieb öffentlicher Schlacht- und Viehhöfe*). In France, in the 15th and 16th centuries, numerous towns had public slaughter-houses. By decrees of Napoleon I. in 1807 and 1810 they were made compulsory in all large towns, the needs of Paris being determined by a Commission, which recommended the establishment of five abattoirs or public slaughter-houses. In 1838 the requirement was extended to all towns, and the slaughter-houses had to be situated at a distance from dwelling-houses. In 1867 the large abattoir of La Villette was constructed in Paris, two of the above five being closed. In 1898 the additional abattoir of Vaugirard was opened, and Villejuif alone remained open for the slaughter of horses for human food.

In Prussia there were 321 public slaughter-houses in 1897. A work published later (*Les Abattoirs publics,* by J. de Loverdo, H. Martel and Mallet, 1906) gives the number of public slaughter-houses as 839 in Germany, 84 in England, 912 in France and nearly 200 in Austria. In some countries slaughter-houses are primitive.

In the British dominions overseas advance is being made. New Zealand has a number of public slaughter-houses and vigorous inspection. Under the Meat Supervision Act of Victoria regulations have been made for Melbourne. Cattle are killed in public slaughter-houses and the carcases are stamped, thus showing in which slaughter-house they have been killed. These steps are necessitated by the frozen meat trade.

Construction.—The planning and construction of public slaughter-houses have been the subject of excellent treatises by German writers, among whom may be mentioned Dr. Oscar Schwarz, of Stolp, and Herr Osthoff, a former city architect of Berlin. The slaughter-house should be situated outside the town, or so placed as to be isolated, and approached by wide roads, so that if cattle are driven through them there should not be interference with the traffic. If possible, the slaughter-house should be connected with the railway system by a branch line, with a platform which has an impervious surface capable of being readily cleansed and disinfected. The most convenient shape of the site is a rectangle or square, having one side abutting on the principal road and another side bounded by the railway. A cattle-market is usually provided in connection with the slaughter-house, and the position should be such that cattle brought by train can be taken immediately into the cattle-market and from the market or the railway to the slaughter-house. The cattle-market should be entirely separate from the slaughter-house area. Osthoff states (*Schlachthöfe für kleine und mittelgrosse Städte*) that the area of the slaughter-house should be as follows:—

			Sq. Metres
Towns of	5,000– 7,000	inhabitants	0·40 per inhabitant.
„ „	7,000–10,000	„	0·35 „ „
„ „	10,000–50,000	„	0·30 „ „
„ „	over 50,000	„	0·25 „ „

In these figures it is assumed that the population derives the whole of its meat-supply from this source.

The parts required, according to Dr. Oscar Schwarz, are: (1)

an administrative block; (2) a slaughtering-hall, with a special room for scalding swine; (3) cattle lairs; (4) room for scalding and cleansing tripe and intestines; (5) an engine-house; (6) separate slaughtering-room, with lairs for animals suffering from, or suspected to be suffering from, contagious disease.

In small towns the slaughtering-hall and room for cleansing intestines may, to save cost of construction, be under the same roof. A necessary adjunct is a cold chamber, to which carcases can be removed from the slaughtering-hall. The actual slaughtering compartment has been built on two plans—one providing a separate slaughtering-room for each butcher, the other a common slaughtering-hall. The latter is greatly to be preferred, inasmuch as it is the only arrangement which gives adequate opportunity for inspection by the officials whose duty it is to examine the meat. The slaughter-house in Berlin was constructed on the separate-room system; but the system gave rise to difficulties of inspection. During recent years in Germany the practice has been to construct slaughter-houses with common halls. Schwarz gives the following as the most convenient arrangement of the buildings: The administrative building (with the house of the superintendent) at the entrance, so that from it the entrance and whole place can be seen. In the vicinity should be a weighing-machine for cattle. The centre of the area is occupied by the slaughtering-halls, and the lairs belonging to them are only separated from them by a road or passage way. The manure-house and tripe-house must be easily accessible from all the slaughtering-halls, but not in direct communication with them.

The manure-house must abut upon a road, to enable its contents to be removed without passing through the premises. Next to the tripe and pig-scalding houses is the engine-house. The building for diseased animals, with the slaughter-house for them, must be isolated from all other buildings. All buildings should be so arranged that they may be capable of extension as the population of the town increases. Cold chambers, although not absolutely essential for small slaughter-houses, are necessary when the slaughter-house is of any size. The cold chamber should be situated opposite the slaughtering-halls, so that carcases can be conveyed by overhead carriers directly from these halls to it. Great attention should be paid to adequate lighting and ventilation, the construction of walls, floors and fittings which are impermeable and can be readily cleansed, and the provision of an abundant water-supply. The floor of the slaughtering-hall is cement or granolithic pavement which must not be so smooth as to be slippery. The floor must have an adequate fall, so that the washings may discharge into the drainage.

Slaughter-houses in Germany pay their own expenses, the fees received for the use of the slaughter-house, and for examination of meat and stamping after examination, providing a sufficient sum for this purpose. The fees vary in different places.

The corporation of the City of London have erected a slaughter-house at their cattle market in Islington in which slaughtering is done in a large hall divided by partitions into separate compartments. The compartments are not let to separate butchers but are used in common. The partitions do not extend to the ceiling, but are sufficiently high to prevent the slaughtering in one compartment being seen by the occupants of other compartments, and thus they necessarily provide less opportunity for inspection than is afforded by the open-slaughtering halls of Germany. The accommodation is estimated as sufficient for the slaughter of 400 cattle, 1,200 sheep and 1,200 calves and pigs per day.

Slaughter-houses in U.S.A.—The centralization of the slaughtering and packing industries in the United States has not required slaughter-houses on the same plan as in Europe. Acts of Congress of 1890, 1891 and 1895 endeavoured to provide some amount of inspection, but sufficient appropriations were never made to carry it out, and there were also certain loopholes in the legislation. Although there were from time to time frequent cases of sickness directly traceable to the consumption of canned meats from the great packing centres, it was not until the publication of Upton Sinclair's *The Jungle* (1906), which dealt with the conditions in the Chicago packing yards, that steps were taken adequately to guard the public against insanitary conditions. A commission of inquiry was appointed by President Roosevelt, and as a result of its report there was passed in 1906 a national meat inspection law. This act required the department of agriculture to appoint inspectors to examine and inspect all cattle, sheep, swine and goats before being allowed to enter into any slaughtering, packing, meat-canning, rendering or similar establishments engaged in interstate commerce. All such animals found to show any symptoms of disease must be set apart and slaughtered separately. All carcases must be inspected and labelled as either "inspected and passed" or "inspected and condemned." Inspection and examination is now carried out very carefully at all stages of the industry, from inspection of the animals before they enter the slaughtering establishments up to the finished product.

The important feature of the Chicago and certain other western American cities slaughter-houses is their adaptation for rapidly dealing with the animals which they receive. At the Chicago slaughter-houses the cattle to be slaughtered are driven up a winding viaduct, by which, in certain of the houses, they eventually reach the roof. Each animal now passes into a narrow pen, where it is at once stunned by a blow on the head. It then falls through a trap-door in the pen into an immense slaughtering-room, where the hind legs are secured, and the animal hoisted to a trolley running on an overhead rail, which leads past numerous workmen, each deputed to carry out a special duty in preparing the carcase on its way to the cooling room which is reached in less than one hour after it has been killed. Any particular carcase or part thereof can be switched out of the line for special inspection without interfering with the onward movement of the others and can be switched back into line if passed by the inspectors. The method of dealing with sheep and swine is essentially the same. One firm alone deals daily with some 10,000 sheep, 12,000 hogs and 3,000 cattle.

Method of Killing.—In 1904 a British departmental (Admiralty) committee on the humane slaughtering of animals recommended that all animals should be stunned before being bled, and, with a view to sparing animals awaiting slaughter the sights and smells of the slaughter-house, that "cattle should, when possible, be slaughtered screened off from their fellows." The aforesaid committee state that they practically tested a large number of appliances designed for felling and stunning animals previous to "pithing," among which they mention the Bruneau and Baxter masks, the Greener patent killer, the Blitz instrument and the Wackett punch, all of which are suitable for quiet cattle or horses. In view of the difficulty of adjusting these instruments in the case of wild or restive animals, the committee express the opinion that the poll-axe when used by an expert is on the whole the most satisfactory implement, but they recommend that no man should be permitted to use the poll-axe on a living animal until he has gone through a thorough course of training, firstly upon a dummy animal and secondly upon dead bodies. Calves, the committee state should be stunned by a blow on the head with a club. With respect to the method of slaughter of sheep the committee discuss the method usually adopted in England, which is "to lay the sheep on a wooden crutch, and then to thrust a knife through the neck below the ears, and with a second motion to insert the point, from within, between the joints of the vertebrae, thus severing the spinal cord." Observations made for the committee by Professor Starling showed that the interval between the first thrust of the knife and complete loss of sensibility varied from five to thirty seconds, and they therefore recommended that sheep should be stunned before being stuck, a practice required in Denmark, many parts of Germany, and Switzerland. It is necessary that the sheep should be struck on the top of the head between the ears and not on the forehead. The insensibility produced by the blow was found to last fully twenty seconds, a period sufficiently long for the killing to be completed if the animal is laid on the crutch before being stunned. The stunning of pigs, the committee recommended, should be insisted upon in all cases, and not, as sometimes at present, only practised in the case of large pigs which give trouble or with a view to the avoidance of noise. Recently in England use of the "humane killer" has been advocated.

The Jewish method of slaughter by cutting the throat was con-

demned by the committee after careful observation, the chief objection being that it fails in the primary requirements of rapidity, freedom from pain and instantaneous loss of sensibility.

SLAVE COAST in West Africa extends from the Gold Coast, that is the river Volta, eastward to the Niger delta; (*see* GUINEA). During the 16th, 17th and 18th centuries, this region was a principal resort of the Europeans engaged in the slave trade. The various districts are now known as Togoland, Dahomey, Lagos, etc. The coast forms the Bight of Benin.

SLAVERY. It appears to be true that, in the words of Dunoyer, the economic régime of every society which has recently become sedentary is founded on the slavery of the industrial professions. In the hunter period the savage warrior does not enslave his vanquished enemy, but slays him; the women of a conquered tribe he may, however, carry off and appropriate as wives or as servants, for in this period domestic labour falls almost altogether on their sex. In the pastoral stage slaves will be captured only to be sold, with the exception of a few who may be required for the care of flocks or the small amount of cultivation which is then undertaken. It is in proportion as a sedentary life prevails, and agricultural exploitation is practised on a larger scale, whilst warlike habits continue to exist, that the labour of slaves is increasingly introduced to provide food for the master, and at the same time save him from irksome toil. Of this stage in the social movement slavery seems to have been, as we have said, a universal and inevitable accompaniment.

But wherever theocratic organizations established themselves slavery in the ordinary sense did not become a vital element in the social system. The members of the lowest class were not in a state of individual subjection: the entire caste to which they belonged was collectively subject. It is in the communities in which the military order obtained an ascendancy over the sacerdotal, and which were directly organized for war, that slavery (as the word is commonly understood) had its natural and appropriate place. It is not merely that in its first establishment slavery was an immense advance by substituting for the immolation of captives, often accompanied by cannibalism, their occupation in labour for the benefit of the victor. This advantage, recalled by an old though erroneous[1] etymology, is generally acknowledged. But it is not so well understood that slavery discharged important offices in the later social evolution—first, by enabling military action to prevail with the degree of intensity and continuity requisite for the system of incorporation by conquest which was its final destination; and, secondly, by forcing the captives, who with their descendants came to form the majority of the population in the conquering community, to an industrial life, in spite of the antipathy to regular and sustained labour which is deeply rooted in human nature. As regards the latter consideration, it is enough to say that nowhere has productive industry developed itself in the form of voluntary effort; in every country of which we have any knowledge it was imposed by the strong upon the weak, and was wrought into the habits of the people only by the stern discipline of constraint. From the former point of view the freeman, then essentially a warrior, and the slave were mutual auxiliaries, simultaneously exercising different and complementary functions—each necessary to the community. In modern slavery, on the other hand, where the occupations of both parties were industrial, the existence of a servile class only guaranteed for some of them the possibility of self-indulgent ease, whilst it imposed on others the necessity of indigent idleness.

It was in the Roman State that military action—in Greece often purposeless and, except in the resistance to Persia, on the whole fruitless—worked out the social mission which formed its true justification. Hence at Rome slavery also most properly found its place, so long as that mission was in progress of accomplishment. As soon as the march of conquest had reached its natural limit, slavery began to be modified; and when the empire was divided into the several States which had grown up under it, and the system of defence characteristic of the middle ages was substituted for the aggressive system of antiquity, slavery gradually disappeared, and was replaced by serfdom.

We have so far dealt with the political results of ancient slavery, and have found it to have been in certain respects not only useful but indispensable. When we consider its moral effects, whilst endeavouring to avoid exaggeration, we must yet pronounce its influence to have been profoundly detrimental. In its action on the slave it marred in a great measure the happy effects of habitual industry by preventing the development of the sense of human dignity which lies at the foundation of morals. On the morality of the masters—whether personal, domestic or social—the effects of the institution were disastrous.

GREECE

We find slavery fully established in the Homeric period. The prisoners taken in war are retained as slaves, or sold (*Il.* xxiv. 752) or held at ransom (*Il.* vi. 427) by the captor. Sometimes the men of a conquered town or district are slain and the women carried off (*Od.* ix. 40). Not unfrequently free persons were kidnapped by pirates and sold in other regions, like Eumaeus in the *Odyssey.* The slave might thus be by birth of equal rank with his master, who knew that the same fate might befall himself or some of the members of his family. The institution does not present itself in a very harsh form in Homer, especially if we consider (as Grote suggests) that "all classes were much on a level in taste, sentiment and instruction." The male slaves were employed in the tillage of the land and the tending of cattle, and the females in domestic work and household manufactures. The principal slaves often enjoyed the confidence of their masters and had important duties entrusted to them; and, after lengthened and meritorious service, were put in possession of a house and property of their own (*Od.* xiv. 64). Grote's idea that the women slaves were in a more pitiable condition than the males does not seem justified, except perhaps in the case of the *aletrides,* who turned the household mills which ground the flour consumed in the family, and who were sometimes overworked by unfeeling masters (*Od.* xx. 110–119). Homer marks in a celebrated couplet his sense of the moral deterioration commonly wrought by the condition of slavery (*Od.* xvii. 322).

Historic Period—Sources of Slavery.—It is, however, in historic Greece, where we have ample documentary information, that it is most important to study the system. The sources of slavery in Greece were: (1) Birth, the condition being hereditary. This was not an abundant source, women slaves being less numerous than men, and wise masters making the union of the sexes rather a reward of good service than a matter of speculation (Xen. *Oecon.* 9. 5). It was in general cheaper to buy a slave than to rear one to the age of labour. (2) Sale of children by their free parents, which was tolerated, except in Attica, or their exposure, which was permitted, except at Thebes. The consequence of the latter was sometimes to subject them to a servitude worse than death, as is seen in the plays of Plautus and Terence, which, as is well known, depict Greek, not Roman, manners. Freemen, through indigence, sometimes sold themselves, and at Athens, up to the time of Solon, an insolvent debtor became the

[1] *Servus* is not cognate with *servare,* as has often been supposed, it is really related to the Homeric εἴρερο and the verb εἴρω, with which the Latin *sero* is to be connected. It may be here mentioned that *slave* was originally a national name; it meant a man of Slavonic race captured and made a bondman to the Germans. "From the Euxine to the Adriatic, in the state of captives or subjects, . . . they [the Slavonians] overspread the land, and the national appellation of the *Slaves* has been degraded by chance or malice from the signification of glory to that of servitude" (Gibbon, *Decline and Fall,* ch. lv.). The historian alludes to the derivation of the national name from *slava,* glory. *See* Skeat's *Etym. Dict., s.v.; see* also SLAVS.

slave of his creditor. (3) Capture in war. Not only Asiatics and Thracians thus became slaves, but in the many wars between Grecian States, continental or colonial, Greeks were reduced to slavery by men of their own race. Callicratidas pronounced against the enslavement of Greeks by Greeks, but violated his own principle, to which, however, Epaminondas and Pelopidas appear to have been faithful. (4) Piracy and kidnapping. The descents of pirates on the coasts were a perpetual source of danger; the pirate was a gainer either by the sale or by the redemption of his captives. If ransomed, the victim became by Athenian law the slave of his redeemer till he paid in money or labour the price which had been given for him. Kidnappers (*andrapodistae*) carried off children even in cities, and reared them as slaves. Whether from hostile forays or from piracy, any Greek was exposed to the risk of enslavement. (5) Commerce. Besides the sale of slaves which took place as a result of the capture of cities or other military operations, there was a systematic slave trade. Syria, Pontus, Lydia, Galatia, and above all Thrace were sources of supply. Egypt and Ethiopia also furnished a certain number, and Italy a few. Of foreigners, the Asiatics bore the greatest value, as most amenable to command, and most versed in the arts of luxurious refinement. But Greeks were highest of all in esteem, and they were much sought for foreign sale. Greece proper and Ionia supplied the petty Eastern princes with courtesans and female musicians and dancers. Athens was an important slave market, and the State profited by a tax on the sales; but the principal marts were those of Cyprus, Samos, Ephesus and especially Chios.

Employment of Slaves.—The slaves were employed either in domestic service—as household managers, attendants or personal escorts—or in work of other kinds, agricultural or urban. In early Attica, and even down to the time of Pericles, the landowners lived in the country. The Peloponnesian War introduced a change; and after that time the proprietors resided at Athens, and the cultivation was in the hands of slaves. In manufactures and commerce, also, servile gradually displaced free labour. Speculators either directly employed slaves as artisans or commercial and banking agents, or hired them out, sometimes for work in mines or factories, sometimes for service in private houses, as cooks, flute-players, etc., or for viler uses. There were also public slaves; of these some belonged to temples, to which they were presented as offerings, amongst them being the courtesans who acted as *hieroduli* at Corinth and at Eryx in Sicily; others were appropriated to the service of the magistrates or to public works; there were at Athens 1,200 Scythian archers for the police of the city; slaves served, too, in the fleets, and were employed in the armies—commonly as workmen, and exceptionally as soldiers.

The condition of slaves at Athens was not in general a wretched one. Demosthenes (*In Mid.* p. 530) says that, if the barbarians from whom the slaves were bought were informed of the mild treatment they received, they would entertain a great esteem for the Athenians. Plautus in more than one place thinks it necessary to explain to the spectators of his plays that slaves at Athens enjoyed such privileges, and even licence, as must be surprising to a Roman audience. The slave was introduced with certain customary rites into his position in the family; he was in practice, though not by law, permitted to accumulate a private fund of his own; his marriage was also recognized by custom; though in general excluded from sacred ceremonies and public sacrifices, slaves were admissible to religious associations of a private kind; there were some popular festivals in which they were allowed to participate; they had even special ones for themselves both at Athens and in other Greek centres. Their remains were deposited in the family tomb of their master, who sometimes erected monuments in testimony of his affection and regret. They often lived on terms of intimacy either with the head of the house or its younger members; but it is to be feared that too often this intimacy was founded, not on mutual respect, as in the heroic example of Ulysses and Eumaeus, but on insolent self-assertion on the one side and a spirit of unworthy compliance on the other, the latter having its *raison d'être* in degrading services rendered by the slave. Aristophanes and Plautus show us how often resort was had to the discipline of the lash even in the case of domestic slaves. Those employed in workshops, whose overseers were themselves most commonly of servile status, had probably a harder lot than domestics; and the agricultural labourers were not unfrequently chained, and treated much in the same way as beasts of burden. The displeasure of the master sometimes dismissed his domestics to the more oppressive labours of the mill or the mine. A refuge from cruel treatment was afforded by the temples and altars of the gods and by the sacred groves. Nor did Athenian law leave the slave without protection. He had, as Demosthenes boasts, an action for outrage like a freeman, and his death at the hand of a stranger was avenged like that of a citizen (Eurip. *Hec.* 288), whilst, if caused by his master's violence, it had to be atoned for by exile and a religious expiation. Even when the slave had killed his master, the relatives of the house could not themselves inflict punishment; they were obliged to hand him over to the magistrate to be dealt with by legal process. The slave who had just grounds of complaint against his master could demand to be sold; when he alleged his right to liberty, the law granted him a defender and the sanctuaries offered him an asylum till judgment should be given. Securities were taken against the revolt of slaves by not associating those of the same nationality and language; they were sometimes fettered to prevent flight, and, after a first attempt at escape, branded to facilitate their recovery. There were treaties between States for the extradition of fugitives, and contracts of mutual assurance between individuals against their loss by flight.

Emancipation.—The slave could purchase his liberty with his *peculium* by agreement with his master. He could be liberated by will, or, during his master's life, by proclamation in the theatre, the law courts or other public places, or by having his name inscribed in the public registers, or, in the later age of Greece, by sale or donation to certain temples—an act which did not make the slave a hierodulus but a freeman. Conditions were sometimes attached to emancipation, as of remaining for life or a definite time with the former master, or another person named by him, or of performing some special service; payments or rights of succession to property might also be reserved. By manumission the Athenian slave became in relation to the State a metic, in relation to his master a client. He was thus in an intermediate condition between slavery and complete freedom. If the freedman violated his duties to his patron he was subject to an action at law, and if the decision were against him, he was again reduced to slavery. He became a full member of the State only, as in the case of foreigners, by a vote in an assembly of 6,000 citizens; and even this vote might be set aside by a *graphē paranomōn.* Slaves who had rendered eminent services to the public, as those who fought at Arginusae and at Chaeronea, were at once admitted to the status of citizens in the class of (so-called) Plataeans. But it would appear that even in their case some civic rights were reserved and accorded only to their children by a female citizen. The number of freedmen at Athens seems never to have been great. (*See* further GREECE: *Ancient History.*)

Theoretic Views on Slavery.—It is well known that Aristotle held slavery to be necessary and natural, and, under just conditions, beneficial to both parties in the relation—views which were correct enough from the political side, regard being had to the contemporary social state. His practical motto, if he is the author of the *Economics* attributed to him, is—"no outrage, and no familiarity." There ought, he says, to be held out to the slave the hope of liberty as the reward of his service. Plato condemned the practice, which the theory of Aristotle also by implication sets aside as inadmissible, of Greeks having Greeks for slaves. In the *Laws* he accepts the institution as a necessary though embarrassing one, and recommends for the safety of the masters that natives of different countries should be mixed and that they should all be well treated. But, whilst condemning harshness towards them, he encourages the feeling of contempt for them as a class. The later moral schools of Greece scarcely at all concern themselves with the institution. The Epicurean had no scruple about the servitude of those whose labours contributed to his

own indulgence and tranquillity. The Stoic regarded the condition of freedom or slavery as an external accident, indifferent in the eye of wisdom; to him it was irrational to see in liberty a ground of pride or in slavery a subject of complaint; from intolerable indignity suicide was an ever-open means of escape. The poets—especially the authors of the New Comedy—strongly inculcate humanity, and insist on the fundamental equality of the slave. The celebrated "homo sum" is a translation from Alexis, and the spirit of it breathes in many passages of the Greek drama. A fragment of Philemon declares, as if in reply to Aristotle, that not nature, but fortune, makes the slave. Euripides, as might be expected from his humanitarian cast of sentiment, and the "premature modernism" which has been remarked in him, rises above the ordinary feelings of his time in regard to the slaves. As Paley says, he loves "to record their fidelity to their masters, their sympathy in the trials of life, their gratitude for kindness and considerate treatment, and their pride in bearing the character of honourable men. . . . He allows them to reason, to advise, to suggest; and he even makes them philosophize on the follies and the indiscretions of their superiors" (compare *Med.* 54; *Orest.* 869; *Hel.* 728; *Ion.* 854; *Frag. Melan.* 506; *Phrix.* 823).

(For the Helots in Laconia, *see* HELOTS.)

ROME

We have already observed that the Roman system of life was that in which slavery had its most natural and relatively legitimate place; and accordingly it was at Rome that, as Blair has remarked, the institution was more than anywhere else "extended in its operations and methodized in its details."

Sources of Slavery.—We must distinguish from the later slavery at Rome what Mommsen calls "the old, in some measure innocent" slavery, under which the farmer tilled the land along with his slave, or, if he possessed more land than he could manage, placed the slave—either as a steward, or as a sort of lessee obliged to render up a portion of the produce—over a detached farm. Though slaves were obtained by the early victories of Rome over her Italian neighbours, no large number was employed on the small holdings of those periods. But the extension of properties in the hands of the patricians, and the continued absences of citizens required by the expanding system of conquest, necessarily brought with them a demand for slave labour, which was increasingly supplied by captives taken in war. Of the number furnished from this source a few particulars from the time of the mature republic and the first century of the empire will give some idea. In Epirus, after the victories of Aemilius Paullus, 150,000 captives were sold. The prisoners at Aquae, Sextiae and Vercellae were 90,000 Teutons and 60,000 Cimbri. Caesar sold on a single occasion in Gaul 63,000 captives. But slavery, as Hume has shown, is unfavourable to population. Hence a regular commerce in slaves was established, which was based on the "systematically-prosecuted hunting of man," and indicated an entire perversion of the primitive institution, which was essentially connected with conquest. The pirates sold great numbers of slaves at Delos, where was the chief market for this kind of wares; and these sales went on as really, though more obscurely, after the successful expedition of Pompey. There was a regular importation to Rome of slaves, brought to some extent from Africa, Spain and Gaul, but chiefly from Asiatic countries—Bithynia, Galatia, Cappadocia and Syria.

There were other sources from which slavery was alimented, though of course in a much less degree. Certain offences reduced the guilty persons to slavery (*servi poenae*), and they were employed in public work in the quarries or the mines. Originally, a father could sell his children. A creditor could hold his insolvent debtor as a slave, or sell him out of the city (*trans Tiberim*). The enslavement of debtors, overwhelmed with usury in consequence of losses by hostile raids or their own absence on military service, led to the secession to the Mons Sacer (493 B.C.). The Poetelian law (326 B.C.) restricted the creditor's lien (by virtue of a *nexum*) to the goods of his debtor, and enacted that for the future no debtor should be put in chains; but we hear of debtors *addicti* to their creditors by the tribunals long after—even in the time of the Punic Wars.

Employment of Slaves.—There were *servi publici* as well as *privati*. The service of the magistrates was at first in the hands of freemen; but the lower offices, as of couriers, servants of the law courts, of prisons and of temples, were afterwards filled by slaves. The execution of public works also came to be largely committed to them—as the construction of roads, the cleansing of the sewers and the maintenance of the aqueducts. Both kinds of functions were discharged by slaves, not only at Rome, but in the rural and provincial municipalities. The slaves of a private Roman were divided between the *familia rustica* and the *familia urbana*. At the head of the *familia rustica* was the *villicus*, himself a slave, with the wife who was given him at once to aid him and to bind him to his duties. Under him were the several groups employed in the different branches of the exploitation and the care of the cattle and flocks, as well as those who kept or prepared the food, clothing and tools of the whole staff and those who attended on the master in the various species of rural sports. A slave prison (*ergastulum*) was part of such an establishment, and there were slaves whose office it was to punish the offences of their fellows. To the *familia urbana* belonged those who discharged the duties of domestic attendance, the service of the toilet, bath, table and kitchen, besides the entertainment of the master and his guests by dancing, singing and other arts. There were, besides, the slaves who accompanied the master and mistress out of doors and were chosen for their beauty and grace as guards of honour, for their strength as chairmen or porters, or for their readiness and address in remembering names, delivering messages of courtesy and the like. There were also attached to a great household physicians, artists, secretaries, librarians, copyists, preparers of parchment, as well as pedagogues and preceptors of different kinds—readers, grammarians, men of letters and even philosophers—all of servile condition, besides accountants, managers and agents for the transaction of business. Actors, comic and tragic, pantomimi, and the performers of the circus were commonly slaves, as were also the gladiators. These last were chosen from the most warlike races—as the Samnites, Gauls and Thracians. *Familiae* of gladiators were kept by private speculators, who hired them out; they were sometimes owned by men of high rank.

Several special examples and other indirect indications show that the wealthier Romans possessed large *familiae*. This may be inferred from the *columbaria* of the house of Livia and of other great houses. The slaves of Pedanius Secundus, who, in spite of a threatened outbreak of the indignant populace, were all put to death because they had been under their master's roof when he was murdered, were 400 in number. Pliny tells us that Caecilius, a freedman of the time of Augustus, left by his will as many as 4,116. The question as to the total number of slaves at Rome or in Italy is a very difficult one, and it is not, perhaps, possible to arrive with any degree of certainty at an approximate estimate. Gibbon supposes that there were in the Roman world in the reign of Claudius at least as many slaves as free inhabitants. But Blair seems right in believing that this number, though probably correct for an earlier period, is much under the truth for the age to which it is assigned. He fixes the proportion of slaves to free men as that of three to one for the time between the conquest of Greece (146 B.C.) and the reign of Alexander Severus (A.D. 222–235). The entire number of slaves in Italy would thus have been, in the reign of Claudius, 20,832,000.

Laws.—By the original Roman law the master was clothed with absolute dominion over the slave, extending to the power of life and death, which is not surprising when we consider the nature of the *patria potestas*. The slave could not possess property of any kind; whatever he acquired was legally his master's. He was, however, in practice permitted to enjoy and accumulate chance earnings or savings, or a share of what he produced, under the name of *peculium*. A master could not enter into a contract with his slave, nor could he accuse him of theft before the law; for, if the slave took anything, this was not a subtraction, but only a displacement, of property. The union of a male and female slave had not the legal character of a marriage; it was a cohabitation

(*contubernium*) merely, which was tolerated, and might be terminated at will, by the master; a slave was, therefore, not capable of the crime of adultery. Yet general sentiment seems to have given a stronger sanction to this sort of connection; the names of husband and wife are freely used in relation to slaves on the stage, and even in the laws, and in the language of the tombs. For entering the military service or taking on him any State office a slave was punished with death. He could not in general be examined as a witness, except by torture. A master, when accused, could offer his slaves for the "question," or demand for the same purpose the slaves of another; and, if in the latter case they were injured or killed in the process, their owner was indemnified. A slave could not accuse his master, except of adultery or incest (under the latter name being included the violation of sacred things or places); the case of high treason was afterwards added to these. An accused slave could not invoke the aid of the tribunes. The penalties of the law for crime were specially severe on slaves.

Treatment of Slaves.—Columella, like Xenophon, favours a certain friendliness and familiarity in one's intercourse with his farm slaves. Cato ate and drank the same coarse victuals as his slaves, and even had the children suckled by his wife, that they might imbibe a fondness for the family. But he had a strict eye to profit in all his dealings with them. He allowed the *contubernium* of male and female slaves at the price of a money payment from their *peculium*. Columella regarded the gains from the births as a sufficient motive for encouraging these unions, and thought that mothers should be rewarded for their fecundity; Varro, too, seems to have taken this view. The immense extension of the rural estates (*latifundia*) made it impossible for masters to know their slaves, even if they were disposed to take trouble for the purpose. Effective superintendence even by overseers became less easy; the use of chains was introduced, and these were worn not only in the field during working hours but at night in the *ergastulum* where the slaves slept. Urban slaves had probably often a life as little enviable, especially those who worked at trades for speculators. Even in private houses at Rome, so late as the time of Ovid, the porter was chained. In the *familia urbana* the favourites of the master had good treatment, and might exercise some influence over him which would lead to their receiving flattery and gifts from those who sought his vote or solicited his support. Doubtless there was often genuine mutual affection; slaves sometimes, as in noted instances during the civil wars, showed the noblest spirit of devotion to their masters. Those who were not inmates of the household, but were employed outside of it as keepers of a shop or boat, chiefs of workshops, or clerks in a mercantile business, had the advantage of greater freedom of action. The slaves of the *leno* and the *lanista* were probably in most cases not only degraded but unhappy. The lighter punishments inflicted by masters were commonly personal chastisement or banishment from the town house to rural labour; the severer were employment in the mill (*pistrinum*) or relegation to the mines or quarries. To the mines also speculators sent slaves; they worked half-naked, men and women, in chains, under the lash and guarded by soldiers. Vedius Pollio, in the time of Augustus, was said to have thrown his slaves, condemned sometimes for trivial mistakes or even accidents, to the lampreys in his fishpond. Cato advised the agriculturist to sell his old oxen and his old slaves, as well as his sick ones; and sick slaves were exposed in the island of Aesculapius in the Tiber; by a decree of Claudius slaves so exposed could not be reclaimed by their masters, in case of their recovery.

Though the Roman slaves were not, like the Spartan Helots, kept obedient by systematic terrorism, their large numbers were a constant source of danger. The law under which the slaves of Pedanius were put to death, probably introduced under Augustus and more fully enacted under Nero, is sufficient proof of this anxiety, which indeed is strongly stated by Tacitus in his narrative of the facts. There had been many conspiracies amongst the slaves in the course of Roman history, and some formidable insurrections. The growth of the *latifundia* made the slaves more and more numerous and formidable. Free labour was discountenanced. Cato, Varro and Columella all agree that slave labour was to be preferred to free except in unhealthy regions and for large occasional operations, which probably transcended the capacity of the permanent *familia rustica*. Cicero and Livy bear testimony to the disappearance of a free plebs from the country districts and its replacement by gangs of slaves working on great estates. The worst form of such predial slavery existed in Sicily, whither Mommsen supposes that its peculiarly harsh features had been brought by the Carthaginians. In Sicily, accordingly, the first really serious servile insurrections took place. The rising under Eunus in 133 B.C. was with some difficulty suppressed by Rupilius. Partial revolts in Italy succeeded; and then came the second Sicilian insurrection under Trypho and Athenio, followed by the Servile War in Italy under Spartacus (*q.v.*). Clodius and Milo used bands of gladiators in their city riots, and this action on the part of the latter was approved by Cicero. In the First Civil War they were to be found in both camps, and the murderers of Caesar were escorted to the Capitol by gladiators. Antony, Octavius, and Sextus Pompeius employed them in the Second Civil War; and it is recorded by Augustus on the Monumentum Ancyranum that he gave back to their masters for punishment about 30,000 slaves who had borne arms against the State.

Blair, in comparing the Greek and Roman systems of slavery, points with justice to the greater facility and frequency of emancipation as the great superiority of the latter. No Roman slave, he says, "needed to despair of becoming both a freeman and a citizen." Manumission was of two kinds—*justa* or regular, and *minus justa*. Of *manumissio justa* there were four modes: (1) by adoption, rarely resorted to; (2) by testament, already recognized in the Twelve Tables; (3) by *census*, which was of exceptional use, and did not exist later than the time of Vespasian; and (4) by *vindicta*, which was the usual form. In the last method the master turned the slave round, with the words "liber esto," in the presence of the praetor, that officer or his lictor at the same time striking the slave with his rod. The *manumissio minus justa* was effected by a sufficient manifestation of the will of the master, as by letter, by words, by putting the *pileus* (or cap of liberty) on the slave, or by any other formality which had by usage become significant of the intention to liberate, or by such an act as making the slave the guardian of his children. This extra-legal sort of manumission was incomplete and precarious; even after the *lex Junia Norbana* (A.D. 19), which assimilated the position of those so liberated to that of the Latin colonists, under the name of Latini juniores, the person remained in the eye of the law a slave till his death and could not dispose of his *peculium* by gift or testamentary disposition.

A freedman, unless he became such by operation of law, remained client of his master, and both were bound by mutual obligations arising out of that relation. These obligations existed also in the case of freedmen of the State, of cities, temples and corporations. The freedman took his former master's name; he owed him deference (*obsequium*) and aid (*officium*); and neglect of these obligations was punished, in extreme cases even with loss of liberty. Conditions might be annexed by the master to the gift of freedom, as of continued residence with him, or of general service or some particular duty to be performed, or of a money payment to be made. But the praetor Rutilius, about the beginning of the 1st century B.C., limited the excessive imposition of such conditions, and his restrictions were carried further by the later jurists and the imperial constitutions. Failing natural heirs of an intestate freedman, the master, now patron, succeeded to his property at his death; and he could dispose by will of only half his possessions, the patron receiving the other half. Freedmen and their sons were subject to civil disabilities; the third generation became *ingenui* (full citizens). Thus the slave element tended to merge itself in the general popular body.

It was often a pecuniary advantage to the master to liberate the slave; he obtained payment which enabled him to buy a substitute and at the same time gained a client. This, of course, presupposes the recognition of the right of the slave to his *peculium;* and the same is implied in Cicero's statement that a diligent slave could in six years purchase his freedom. Augustus set himself against the undue multiplication of manumissions, probably

considering the rapid succession of new citizens a source of social instability, and recommended a similar policy to his successor. The lex Aelia Sentia (about A.D. 3) forbade manumission, except in strictly limited cases, by masters under 20 years of age or of slaves under 30; and the lex Furia Caninia (about A.D. 7) fixed the proportion of a man's slaves which he could liberate by testament, and forbade more than 100 being so enfranchised, whatever might be the number of the *familia*. Under the empire the freedmen rose steadily in influence; they became admissible to the rank of equites and to the senate; they obtained provincial Governments, and were appointed to offices in the imperial household which virtually placed them at the head of administrative departments. (*See* article on NARCISSUS.) Freedmen of humbler rank, on the other hand, filled the minor offices in the administrative service, in the city cohorts, and in the army; and we shall find that they entered largely into the trades and professions when free labour began to revive. They appeared also in literature, *e.g.*, Tiro, the amanuensis of Cicero; Hyginus, the librarian of Augustus; Livius Andronicus, Caecilius, Statius, Terence, Publilius Syrus, Phaedrus and Epictetus.

In the 2nd century of the Christian era we find a marked change with respect to the institution of slavery, both in the region of thought and in that of law. Already the principles of reason and humanity had been applied to the subject by Seneca. But it was in the 2nd century, as we have said, that "the victory of moral ideas" in this, as in other departments of life, became "decisive. . . . Dio Chrysostom, the adviser of Trajan, is the first Greek writer who has pronounced the principle of slavery to be contrary to the law of nature" (Mark Pattison). And a parallel change is found in the practical policy of the State. The military vocation of Rome was now felt to have reached its normal limits; and the emperors, understanding that, in the future, industrial activity must prevail, prepared the abolition of slavery as far as was then possible, by honouring the freedmen, by protecting the slave against his master, and by facilitating manumissions. The general tendency both of the imperial constitutions and of the maxims of the legists is in favour of liberty. The practices of exposure and sale of children, and of giving them in pledge for debt, are forbidden. Diocletian forbade a free man to sell himself. Kidnappers (*plagiarii*) were punished with death. The insolvent debtor was withdrawn from the yoke of his creditor. While the slave trade was permitted, the mutilation of boys and young men, too often practised, was punished with exile and even with death. In redhibitory actions (for the annulment of sales), if a slave were returned to the seller, so must also be his parents, brothers and *personae contubernio conjunctae*. In the interpretation of testaments it was to be assumed that members of the same family were not to be separated by the division of the succession. The law also favoured in special cases the security of the *peculium*, though in general principle it still remained the property of the master. The State granted to public slaves the right of bequeathing half their possessions; and private persons sometimes permitted similar dispositions even to a greater extent, though only within the *familia*. Hadrian took from masters the power of life and death and abolished the subterranean prisons. Antoninus Pius punished him who killed his own slave as if he had killed another's. Already in the time of Nero the magistrates had been ordered to receive the slave's complaint of ill-treatment; and the *lex Petronia*, belonging to the same or an earlier period, forbade masters to hand over their slaves to combats with wild beasts. M. Aurelius gave to masters an action against their slaves for any cause of complaint, thus bringing their relation more directly under the surveillance of law and public opinion. A slave's oath could still not be taken in a court of law; he was interrogated by the "question"; but the emperors and jurists limited in various ways the application of torture, adding, however, as we have mentioned, to the cases in which it could previously be appealed to that of the crime of *majestas*. For certain alleged offences of the master the slave could bring an action, being represented for the purpose by an *adsertor*. Emancipation was facilitated. The power of imposing conditions on testamentary manumissions was restricted, and these conditions interpreted in the sense most favourable to freedom. The emperor could confer liberty by presenting a gold ring to a slave with the consent of the master, and the legal process called *restitutio natalium* made him a full citizen.

Influence of Christianity.—The rise of Christianity in the Roman world still further improved the condition of the slave. The sentiments it created were not only favourable to the humane treatment of the class in the present, but were the germs out of which its entire liberation was destined, at a later period, in part to arise. It is sometimes objected that the Christian Church did not denounce slavery as a social crime and insist on its abolition. We have seen that slavery was a fundamental element of the old Roman constitution. When the work of conquest had been achieved, it could not be expected that a radical alteration should be suddenly wrought either in the social system which was in harmony with it, or even in the general ideas which had grown up under its influence. The latter would, indeed, be gradually affected; and accordingly, we have observed a change in the policy of the law, indicating a change in sentiment with respect to the slave class, which does not appear to have been at all due to Christian teaching. But the institution itself could not be at once seriously disturbed. The results must have been disastrous, most of all to the slave population itself. Before that end could be accomplished, an essentially new social situation must come into existence. But in the meantime much might be done towards further mitigating the evils of slavery, especially by impressing on master and slave their relative duties and controlling their behaviour towards one another by the exercise of an independent moral authority. This was the work open to the Christian priesthood, and it cannot be denied that it was well discharged. Whilst the fathers agree with the Stoics of the 2nd century in representing slavery as an indifferent circumstance in the eye of religion and morality, the contempt for the class which the Stoics too often exhibited is in them replaced by a genuine sympathy. They protested against the multiplication of slaves from motives of vanity in the houses of the great, against the gladiatorial combats (ultimately abolished by the noble self-devotion of a monk) and against the consignment of slaves to the theatrical profession, which was often a school of corruption. The Church also encouraged the emancipation of individual slaves and the redemption of captives. And its influence is to be seen in the legislation of the Christian emperors, which softened some of the harshest features that still marked the institution. But a stronger influence of Christianity appears in Theodosius, and this influence is at the highest in the legislation of Justinian. Its systematic effort is, in his own words, "pro libertate, quam et fovere et tueri Romanis legibus et praecipue nostro numini peculiare est." Law still refused in general to recognize the marriages of slaves; but Justinian gave them a legal value after emancipation in establishing rights of succession. Unions between slaves and free women, or between a freeman and the female slave of another, continued to be forbidden, and were long punished in certain circumstances with atrocious severity. As witness, the slave was still subject to the question; as criminal, he was punished with greater rigour than the freeman. If he accused his master of a crime, unless the charge was of treason, he was burnt. But he could maintain a legal claim to his own liberty, not now merely through an *adsertor*, but in person. A female slave was still held incapable of the offence of adultery; but Justinian visited with death alike the rape of a slave or freedwoman and that of a free maiden. Already the master who killed his slave had been punished as for homicide, except in the case of his unintended death under correction; Constantine treated as homicide a number of specially enumerated acts of cruelty. Even under Theodosius the combats of the amphitheatre were permitted, if not encouraged, by the State authorities; these sports were still expected from the candidates for public honours. Combats of men with beasts were longest continued; they had not ceased even in the early years of the reign of Justinian. A new process of manumission was now established, to be performed in the churches through the intervention of the ministers of religion; and it was provided that clerics could at any time by mere expression of will liberate their slaves. Slaves who were admitted to holy orders, or who entered a monastery, became freemen.

under certain restrictions framed to prevent fraud or injustice. Justinian abolished the personal conditions which the legislation of Augustus had required to be satisfied by the master who emancipated and the slave who was manumitted, and removed the limitation of number. The liberated slave, whatever the process by which he had obtained his freedom, became at once a full citizen, his former master, however, retaining the right of patronage, the abolition of which would probably have discouraged emancipation.

Transition to Serfdom.—The slavery of the working classes was not directly changed into the system of personal freedom. There was an intermediate stage which has not always been sufficiently discriminated from slavery. We mean the régime of serfdom. In studying the origin of this transitional state of things, four principal considerations have to be kept in view. (1) As Gibbon observes, the completion of the Roman system of conquest reduced the supply of slaves. It is true that, when the barbarian invasions began in the 3rd century, many captives were made, who, when not enrolled in the army, were employed in agriculture or domestic service; but the regular importation was increasingly diminished. This improved the condition of the slave by rendering his existence an object of greater value to his master. It was clearly to the interest of each family to preserve indefinitely its own hereditary slaves. Hence the abolition of the external slave trade tended, in fact, to put an end to internal sales, and the slaves became attached to the households or lands of their masters. (2) The diminished supply of slaves further acted in the direction of the rehabilitation of free labour. A general movement of this kind is noticeable from the 2nd century onwards. Freemen had always been to some extent employed in the public service. In private service superior posts were often filled by freedmen; the higher arts—as medicine, grammar, painting—were partly in the hands of freedmen and even of *ingenui;* the more successful actors and gladiators were often freedmen. In the factories or workshops kept by wealthy persons slave labour was mainly employed; but free artisans sometimes offered their services to these establishments or formed associations to compete with them. We have seen that free persons had all along been to some extent employed in the cultivation of land as hired labourers, and, as we shall presently find, also as tenants on the great estates. How all this operated we shall understand when we examine the remarkable organization of the State introduced by Diocletian and his successors. (3) This organization established in the Roman world a personal and hereditary fixity of professions and situations which was not very far removed from the caste system of the East. The purpose of this was doubtless to resist by a strong internal consolidation the shock of the invasions, to secure public order, to enforce industrious habits, and to guarantee the financial resources of the State. Personal independence was largely sacrificed, but those still more important ends were in a great measure attained. This system, by diminishing the freeman's mastery over himself and his power to determine his occupation, reduced the interval between him and the slave; and the latter on the one hand, the free domestic servant and workshop labourer on the other, both passed insensibly into the common condition of serfdom. (4) The corresponding change, in the case of the rural slaves, took place through their being merged in the order of *coloni.* The Roman *colonus* was originally a free person who took land on lease contracting to pay to the proprietor either a fixed sum annually or (when a *colonus partiarius*) a certain proportion of the produce of the farm. Under the emperors of the 4th century the name designated a cultivator who, though personally free, was attached to the soil, and transmitted his condition to his descendants; and this became the regular status of the mass of Roman cultivators. The class of coloni appears to have been composed partly of tenants by contract who had incurred large arrears of rent and were detained on the estates as debtors (*obaerati*), partly of foreign captives or immigrants who were settled in this condition on the land, and partly of small proprietors and other poor men who voluntarily adopted the status as an improvement in their position. They paid a fixed proportion of the produce (*pars agraria*) to the owner of the estate, and gave a determinate amount of labour (*operae*) on the portion of the domain which he kept in his own hands (*mansus dominicus*). The law for a long time took no notice of these customary tenures, and did not systematically constitute them until the 4th century. It was, indeed, the requirements of the fiscus and the conscription which impelled the imperial Government to regulate the system. The coloni were inscribed (*adscripti*) on the registers of the census as paying taxes to the State, for which the proprietor was responsible, reimbursing himself for the amount. In a constitution of Constantine (A.D. 332) we find the colonus recognized as permanently attached to the land. If he abandoned his holding he was brought back and punished; and anyone who received him had not only to restore him but to pay a penalty. He could not marry out of the domain; if he took for wife a colona of another proprietor, she was restored to her original locality, and the offspring of the union were divided between the estates. The children of a colonus were fixed in the same status. They and their descendants were retained, in the words of a law of Theodosius, "quodam aeternitatis jure," and by no process could be relieved from their obligations. By a law of Anastasius, at the end of the 5th century, a colonus who had voluntarily come into an estate was by a tenure of 30 years for ever attached to it. The master (*dominus*) could inflict on his coloni "moderate chastisement," and could chain them if they attempted to escape, but they had a legal remedy against him for unjust demands or injury to them or theirs. In no case could the rent or the labour dues be increased. The colonus could possess property of his own, but could not alienate it without the consent of the master. Thus, whilst the members of the class were personally free, their condition had some incidents of a semi-servile character. They are actually designated by Theodosius, "servi terrae cui nati sunt." And Salvian treats the proposition "coloni divitum fiunt" as equivalent to "vertuntur in servos." This is, indeed, an exaggeration; the *colonatus* was not an oppressive system; it afforded real security against unreasonable demands and wanton disturbance, and it was a great advance on the system of the *familia rustica.* But the point which is important is that there was a certain approximation between the condition of the colonus and the slave which tended towards the fusion of both in a single class.

Besides the coloni there were on a great estate—and those of the 4th century were on a specially large scale—a number of predial slaves, who worked collectively under overseers on the part of the property which the owner himself cultivated. But it was a common practice to settle certain of the slaves (and possibly also of the freedmen) on other portions of the estate, giving them small farms on conditions similar to those to which the coloni were subject. These slaves are, in fact, described by Ulpian as *quasi coloni.* They had their own households and were hence distinguished as *casati.* In law these slaves were at first absolutely at the disposal of their masters; they had no property in the strict sense of the word, and could be sold to another proprietor and separated from their families. But the landlord's interest and the general tone of feeling alike modified practice even before the intervention of legislation; they were habitually continued in their holdings, and came to possess in fact a perpetual and hereditary enjoyment of them. By a law of Valentinian I. (377) the sale of these slaves was interdicted unless the land they occupied was at the same time sold. The legal distinction between the coloni and the slave tenants continued to exist after the invasions; but the practical difference was greatly attenuated. The colonus often occupied a servile mansus, and the slave a mansus originally appropriated to a colonus. Intermarriages of the two classes became frequent. Already at the end of the 7th century it does not appear that the distinction between them had any substantial existence.

The influence of the Northern invasions on the change from slavery to serfdom was, in all probability, of little account. The change would have taken place, though perhaps not so speedily, if they had never occurred. For the developments of the middle ages *see* SERFDOM and VILLEINAGE.

MODERN SLAVE TRADE

Not very long after the disappearance of serfdom in the most

advanced communities comes into sight the new system of colonial slavery, which, instead of being the spontaneous outgrowth of social necessities and subserving a temporary need of human development, was politically as well as morally a monstrous aberration.

Spanish Colonies.—In 1442, when the Portuguese under Prince Henry the Navigator were exploring the Atlantic coast of Africa, one of his officers, Antam Gonsalves, who had captured some Moors, was directed by the prince to carry them back to Africa. He received from the Moors in exchange for them ten blacks and a quantity of gold dust. This excited the cupidity of his fellow-countrymen; and they fitted out a large number of ships for the trade, and built several forts on the African coast. Many negroes were brought into Spain from these Portuguese settlements, and the colonial slave trade first appears in the form of the introduction into the newly discovered western world of descendants of these negroes. When Nicolas de Ovando was sent out in 1502 as governor of Haiti, whilst regulations, destined to prove illusory, were made for the protection of the natives of the island, permission was given to carry to the colony negro slaves, born in Seville and other parts of Spain, who had been instructed in the Christian faith. It appears from a letter of Ovando in 1503 that there were at that time numbers of negroes in Haiti; he requested that no more might be permitted to be brought out. In 1510 and the following years King Ferdinand ordered a number of Africans to be sent to that colony for the working of the mines.

Before this time Columbus had proposed an exchange of his Carib prisoners as slaves against live stock to be furnished to Haiti by Spanish merchants. He actually sent home, in 1494, above 500 Indian prisoners taken in wars with the caciques, who, he suggested, might be sold as slaves at Seville. But, after a royal order had been issued for their sale, Queen Isabella, interested by what she had heard of the gentle and hospitable character of the natives and of their docility, procured a letter to be written to Bishop Fonseca, the superintendent of Indian affairs, suspending the order until enquiry should be made into the causes for which they had been made prisoners, and into the lawfulness of their sale. Theologians differed on the latter question, and Isabella directed that these Indians should be sent back to their native country.

Bartolomé de las Casas, the celebrated bishop of Chiapa, accompanied Ovando to Haiti, and was a witness of the cruelties from which the Indians suffered under his administration. He came to Spain in 1517 to obtain measures in their favour, and he then made the suggestion to Charles that each Spanish resident in Haiti should have licence to import a dozen negro slaves. Las Casas, in his *Historia de las Indias* (lib. iii. cap. 101), confesses the error into which he thus fell. Other good men appear to have given similar advice about the same time, and, as has been shown, the practice was not absolutely new; indeed, the young king had in 1516, whilst still in Flanders, granted licences to his courtiers for the importation of negroes into the colonies, though Jimenes, as regent of Castile, by a decree of the same year forbade the practice. The suggestion of Las Casas was no doubt made on the ground that the negroes could, better than the Indians, bear the labour in the mines, which was rapidly exhausting the numbers of the latter. He has sometimes on this plea been exonerated from all censure; but, though entitled to honour for the zeal which he showed on behalf of the natives, he must bear the blame for his violation or neglect of moral principle. His advice was unfortunately adopted. "Charles," says Robertson, "granted a patent to one of his Flemish favourites, containing an exclusive right" of supplying 4,000 negroes annually to Haiti, Cuba, Jamaica and Porto Rico. "The favourite sold his patent to some Genoese merchants for 25,000 ducats"; these merchants obtained the slaves from the Portuguese; and thus was first systematized the slave trade between Africa and America.

England.—The first Englishman who engaged in the traffic was Sir John Hawkins (*q.v.*). The English slave traders were at first altogether occupied in supplying the Spanish settlements. Indeed, the reign of Elizabeth passed without any English colony having been permanently established in America. But in 1620 a Dutch ship from the coast of Guinea visited Jamestown in Virginia, and sold a part of her cargo of negroes to the tobacco-planters. This was the beginning of slavery in British America; the number of negroes was afterwards continually increased—though apparently at first slowly—by importation, and the field-labour was more and more performed by servile hands, so that in 1790 the State of Virginia contained 200,000 negroes.

The African trade of England was long in the hands of exclusive companies; but by an act of the first year of William and Mary it became free and open to all subjects of the Crown. The African company, however, continued to exist, and obtained from time to time large parliamentary grants. By the Treaty of Utrecht, the asiento, or contract for supplying the Spanish colonies with 4,800 negroes annually, which had previously passed from the Dutch to the French, was transferred to Great Britain; an English company was to enjoy the monopoly for a period of 30 years from May 1, 1713. But the contract came to an end in 1739, when the complaints of the English merchants on one side and of the Spanish officials on the other rose to such a height that Philip V. declared his determination to revoke the asiento, and Sir Robert Walpole was forced by popular feeling into war with Spain. Between 1680 and 1700 about 140,000 negroes were exported by the African company, and 160,000 more by private adventurers, making a total of 300,000. Between 1700 and the end of 1786 as many as 610,000 were transported to Jamaica alone, which had been an English possession since 1655. Bryan Edwards estimated the total import into all the British colonies of America and the West Indies from 1680 to 1786 at 2,130,000, being an annual average of 20,095. The British slave trade reached its utmost extension shortly before the War of American Independence. It was then carried on principally from Liverpool, but also from London, Bristol and Lancaster: the entire number of slave ships sailing from those ports was 192 and in them space was provided for the transport of 47,146 negroes. During the war the number decreased, but on its termination the trade immediately revived. When Edwards wrote (1791), the number of European factories on the coasts of Africa was 40; of these 14 were English, 3 French, 15 Dutch, 4 Portuguese and 4 Danish. As correct a notion as can be obtained of the numbers annually exported from the continent about the year 1790 by traders of the several European countries engaged in the traffic is supplied by the following statement: "By the British, 38,000; by the French, 20,000; by the Dutch, 4,000; by the Danes, 2,000; by the Portuguese, 10,000; total 74,000." Thus more than half the trade was in British hands.

The hunting of human beings to make them slaves was greatly aggravated by the demand of the European colonies. The native chiefs engaged in forays, sometimes even on their own subjects, for the purpose of procuring slaves to be exchanged for Western commodities. They often set fire to a village by night and captured the inhabitants when trying to escape. Thus all that was shocking in the barbarism of Africa was multiplied and intensified by this foreign stimulation. Exclusive of the slaves who died before they sailed from Africa, 12½% were lost during their passage to the West Indies; at Jamaica 4½% died whilst in the harbours or before the sale and one-third more in the "seasoning." Thus, out of every lot of 100 shipped from Africa 17 died in about 9 weeks, and not more than 50 lived to be effective labourers in the islands. The circumstances of their subsequent life on the plantations were not favourable to the increase of their numbers. In Jamaica there were in 1690, 40,000; from that year till 1820 there were imported 800,000; yet at the latter date there were only 340,000 in the island. One cause which prevented the natural increase of population was the inequality in the numbers of the sexes; in Jamaica alone there was in 1789 an excess of 30,000 males.

Movement Against the Slave Trade.—When the nature of the slave trade began to be understood by the public, all that was best in England was adverse to it. Among those who denounced it—besides some whose names are now little known, but are recorded in the pages of Clarkson—were Baxter, Sir Richard Steele

(in *Inkle and Yarico*), the poets Southern (in *Oroonoko*), Pope, Thomson, Shenstone, Dyer, Savage and above all Cowper (*see* his *Charity,* and *Task,* bk. 2), Thomas Day (author of *Sandford and Merton*), Sterne, Warburton, Hutcheson, Beattie, John Wesley, Whitfield, Adam Smith, Millar, Robertson, Dr. Johnson, Paley, Gregory, Gilbert Wakefield, Bishop Porteus, Dean Tucker. The question of the legal existence of slavery in Great Britain and Ireland was raised in consequence of an opinion given in 1729 by Yorke and Talbot, attorney-general and solicitor-general at the time, to the effect that a slave by coming into those countries from the West Indies did not become free, and might be compelled by his master to return to the plantations. Chief-justice Holt had expressed a contrary opinion; and the matter was brought to a final issue by Granville Sharp in the case of the negro Somerset. It was decided by Lord Mansfield, in the name of the whole bench, on June 22, 1772, that as soon as a slave set his foot on the soil of the British islands he became free. In 1776 it was moved in the House of Commons by David Hartley, son of the author of *Observations on Man,* that "the slave trade was contrary to the laws of God and the rights of men"; but this motion—the first which was made on the subject—failed.

The first persons in England who took united practical action against the slave trade were the Quakers, following the expression of sentiment which had emanated as early as 1671 from their founder George Fox. In 1727 they declared it to be "not a commendable or allowed" practice; in 1761 they excluded from their society all who should be found concerned in it, and issued appeals to their members and the public against the system. In 1783 there was formed among them an association "for the relief and liberation of the negro slaves in the West Indies, and for the discouragement of the slave trade on the coast of Africa." This was the first society established in England for the purpose. The Quakers in America had taken action on the subject still earlier than those in England. The Pennsylvanian Quakers advised their members against the trade in 1696; in 1754 they issued to their brethren a strong dissuasive against encouraging it in any manner; in 1774 all persons concerned in the traffic, and in 1776 all slave holders who would not emancipate their slaves, were excluded from membership. The Quakers in the other American provinces followed the lead of their brethren in Pennsylvania. The individuals among the American Quakers who laboured most earnestly and indefatigably on behalf of the Africans were John Woolman (1720–73) and Anthony Benezet (1713–84), the latter a son of a French Huguenot driven from France by the revocation of the Edict of Nantes. The former confined his efforts chiefly to America and, indeed, to his co-religionists there; the latter sought, not without success, to found a universal propaganda in favour of abolition. A Pennsylvanian society was formed in 1774 by James Pemberton and Dr. Benjamin Rush, and in 1787 (after the war) was reconstructed on an enlarged basis under the presidency of Franklin. Other similar associations were founded about the same time in different parts of the United States. The next important movement took place in England. Dr. Peckard, vice-chancellor of the University of Cambridge, who entertained strong convictions against the slave trade, proposed in 1785 as subject for a Latin prize dissertation the question, "An liceat invitos in servitutem dare." Thomas Clarkson obtained the first prize, translated his essay into English in an expanded form, and published it in 1786 with the title *Essay on the Slavery and Commerce of the Human Species*. In the process of its publication he was brought into contact with several persons already deeply interested in the question; amongst others with Granville Sharp, William Dillwyn (an American by birth, who had known Benezet), and the Rev. James Ramsay, who had lived 19 years in St. Christopher, and had published an *Essay on the Treatment and Conversion of the African Slaves in the British Sugar Colonies*. The distribution of Clarkson's book led to his forming connections with many persons of influence, and especially with William Wilberforce (*q.v.*). A committee was formed on May 22, 1787, for the abolition of the slave trade, under the presidency of Granville Sharp. It is unquestionable that the principal motive power which originated and sustained their efforts was Christian principle and feeling. The most earnest and unremitting exertions were made by the persons so associated in investigating facts and collecting evidence, in forming branch committees and procuring petitions, information and support of those who pleaded the cause in parliament. To the original members were afterwards added several remarkable persons, amongst whom were Josiah Wedgwood, Bennet Langton (Dr. Johnson's friend), and, later, Zachary Macaulay, Henry Brougham and James Stephen.

In consequence of the numerous petitions presented to parliament, a committee of Privy Council was appointed by the Crown in 1788 to enquire concerning the slave trade; and Pitt moved that the House of Commons should early in the next session take the subject into consideration. Wilberforce's first motion for a committee of the whole House upon the question was made on March 19, 1789, and this committee proceeded to business on May 12 of the same year. After an admirable speech, Wilberforce laid on the table 12 resolutions which were intended as the basis of a future motion for the abolition of the trade. The discussion of these was postponed to the next session, and in 1790–91 evidence was taken upon them. At length, on April 18 of the latter year, a motion was made for the introduction of a bill to prevent the further importation of slaves into the British colonies in the West Indies. Opinion had been prejudiced by the insurrections in St. Domingo and Martinique, and in the British island of Dominica; and the motion was defeated by 163 votes against 88. Legislative sanction was, however, given to the establishment of the Sierra Leone company, for the colonization of a district on the west coast of Africa and the discouragement of the slave trade there. It was hoped at the time that that place would become the centre from which the civilization of Africa would proceed; but this expectation was not fulfilled. On April 2, 1792 Wilberforce again moved that the trade ought to be abolished; an amendment in favour of gradual abolition was carried, and it was finally resolved that the trade should cease on Jan. 1, 1796. When a similar motion was brought forward in the Lords the consideration of it was postponed to the following year, in order to give time for the examination of witnesses by a committee of the House. A bill in the Commons in the following year to abolish that part of the trade by which British merchants supplied foreign settlements with slaves was lost on the third reading; it was renewed in the Commons in 1794 and carried there, but defeated in the Lords. Then followed several years during which efforts were made by the abolitionists in parliament with little success. But in 1806, Lord Grenville and Fox having come into power, a bill was passed in both Houses to put an end to the British slave trade for foreign supply, and to forbid the importation of slaves into the colonies won by the British arms in the course of the war. On June 10 of the same year Fox brought forward a resolution "that effectual measures should be taken for the abolition of the African slave trade in such a manner and at such a period as should be deemed advisable," which was carried by a large majority. A similar resolution was successful in the House of Lords. A bill was then passed through both Houses forbidding the employment of any new vessel in the trade. Finally, in 1807, a bill was presented by Lord Grenville in the House of Lords providing for the abolition of the trade, was passed by a large majority, was then sent to the Commons (where it was moved by Lord Howick), was there amended and passed, and received the royal assent on March 25. The bill enacted that no vessel should clear out for slaves from any port within the British dominions after May 1, 1807, and that no slave should be landed in the colonies after March 1, 1808.

In 1807 the African Institution was formed, with the primary objects of keeping a vigilant watch on the slave traders and procuring, if possible, the abolition of the slave trade by the other European nations. It was also to be made an instrument for promoting the instruction of the negro races and diffusing information respecting the African continent.

The act of 1807 was habitually violated, as the traders knew that, if one voyage in three was successful, they were abundantly remunerated for their losses. This state of things, it was plain,

must continue as long as the trade was only a contraband commerce, involving merely pecuniary penalties. Accordingly, in 1811, Brougham carried through parliament a bill declaring the traffic to be a felony punishable with transportation. Some years later another act was passed, making it a capital offence; but this was afterwards repealed. The law of 1811 proved effectual and brought the slave trade to an end so far as the British dominions were concerned.

French Abolition.—The abolition of the French slave trade was preceded by struggles and excesses. The western part of St. Domingo, nominally belonging to Spain, had been occupied by buccaneers, who were recognized and supported by the French Government, and had been ceded to France at the Peace of Ryswick in 1697. So vast was the annual importation of enslaved negroes into this colony before 1791 that the ratio of the blacks to the whites was as 16 to 1. In that year there were in French St. Domingo 480,000 blacks, 24,000 mulattoes and only 30,000 whites. The French law for the regulation of slavery in the plantations, known as the *Code Noir* (framed under Louis XIV. in 1685), was humane in its spirit; but we are informed that its provisions were habitually disregarded by the planters, whilst the free mulattoes laboured under serious grievances and were exposed to irritating indignities. A "Société des Amis des Noirs" was formed in Paris in 1788 for the abolition, not only of the slave trade, but of slavery itself. The president was Condorcet, and amongst the members were the duc de la Rochefoucault, the abbé Gregoire, Brissot, Clavière, Pétion and La Fayette; Mirabeau was an active sympathizer. The great motor of the parallel effort in England was the Christian spirit; in France it was the enthusiasm of humanity which was associated with the revolutionary movement. There were in 1789 a number of mulattoes in Paris, who had come from San Domingo to assert the rights of the people of colour in that colony before the national assembly. The Declaration of the Rights of Man in Aug. 1789 seemed to meet their claims, but in March 1790 the assembly, alarmed by rumours of the discontent and disaffection of the planters in San Domingo, passed a resolution that it had not been intended to comprehend the internal government of the colonies in the constitution framed for the mother country. Vincent Ogé, one of the mulatto delegates in Paris, disgusted at the overthrow of the hopes of his race, returned to San Domingo, and on landing in Oct. 1790 addressed a letter to the governor announcing his intention of taking up arms on behalf of the mulattoes if their wrongs were not redressed. He rose accordingly with a few followers, but was soon defeated and forced to take refuge in the Spanish part of the island. He afterwards surrendered, was tried and sentenced to be broken on the wheel. When the news of this reached Paris, it created a strong feeling against the planters; and on the motion of the abbé Gregoire it was resolved by the assembly on May 15, 1791 "that the people of colour resident in the French colonies, born of free parents, were entitled to, as of right, and should be allowed, the enjoyment of all the privileges of French citizens, and among others those of being eligible to seats both in the parochial and colonial assemblies." On Aug. 23 a rebellion of the negroes broke out in the northern province of San Domingo, and soon extended to the western province, where the mulattoes and blacks combined. Many enormities were committed by the insurgents, and were avenged with scarcely inferior barbarity. The French assembly, fearing the loss of the colony, repealed on Sept. 24 the decree of the preceding May. This vacillation put an end to all hope of a reconciliation of parties in the island. Civil commissioners sent out from France quarrelled with the governor and called the revolted negroes to their assistance. The white inhabitants of Cape François were massacred and the city in great part destroyed by fire. The planters now offered their allegiance to Great Britain; and an English force landed in the colony. But it was insufficient to encounter the hostility of the republican troops and the revolted negroes and mulattoes; it suffered from disease, and was obliged to evacuate the island in 1798. On the departure of the British the Government remained in the hands of Toussaint l'Ouverture (*q.v.*). Slavery had disappeared; the blacks were employed as hired servants, receiving for their remuneration the third part of the crops they raised; and the population was rapidly rising in civilization and comfort. The whole island was now French, the Spanish portion having been ceded by the Treaty of Basle. The wish of Toussaint was that San Domingo should enjoy a practical independence whilst recognizing the sovereignty and exclusive commercial rights of France. The issue of the violent and treacherous conduct of Bonaparte towards the island was that the blacks drove from their soil the forces sent to subdue them, and founded a constitution of their own, which was more than once modified. There can be no doubt that the Government of the Restoration, in seeking to obtain possession of the island, had the intention of re-establishing slavery, and even of reopening the slave trade for the purpose of recruiting the diminished population. But Bonaparte abolished that trade during the Hundred Days, though he also failed to win back the people of San Domingo, or, as it was now called by its original name, Haiti, to obedience. The Bourbons, when again restored, could not reintroduce the slave trade; the notion of conquering the island had to be given up; and its independence was formally recognized in 1825. (*See* HAITI.)

Progress of the Movement.—England had not been the first European Power to abolish the slave trade; that honour belongs to Denmark; a royal order was issued on May 16, 1792 that the traffic should cease in the Danish possessions from the end of 1802. The United States had in 1794 forbidden any participation by American subjects in the slave trade to foreign countries; they now prohibited the importation of slaves from Africa into their own dominions. This act was passed on March 2, 1807; it did not, however, come into force till Jan. 1, 1808. At the Congress of Vienna (Nov. 1814) the principle was acknowledged that the slave trade should be abolished as soon as possible; but the determination of the limit of time was reserved for separate negotiation between the Powers. It had been provided in a treaty between France and Great Britain (May 30, 1814) that no foreigner should in future introduce slaves into the French colonies, and that the trade should be absolutely interdicted to the French themselves after June 1, 1819. This postponement of abolition was dictated by the wish to introduce a fresh stock of slaves into Haiti, if that island should be recovered. Bonaparte, as we have seen, abolished the French slave trade during his brief restoration, and this abolition was confirmed at the second Peace of Paris on Nov. 20, 1815, but it was not effectually carried out by French legislation until March 1818. In Jan. 1815 Portuguese subjects were prohibited from prosecuting the trade north of the equator, and the term after which the traffic should be everywhere unlawful was fixed to end on Jan. 21, 1823, but was afterwards extended to Feb. 1830; England paid £300,000 as a compensation to the Portuguese. A royal decree was issued on Dec. 10, 1836, forbidding the export of slaves from any Portuguese possession. But this decree was often violated. It was agreed that the Spanish slave trade should come to an end in 1820, England paying to Spain an indemnification of £400,000. The Dutch trade was closed in 1814; the Swedish had been abolished in 1813. By the Peace of Ghent, Dec. 1814, the United States and England mutually bound themselves to do all in their power to extinguish the traffic. It was at once prohibited in several of the South American States when they acquired independence, as in La Plata, Venezuela and Chile. In 1831 and 1833 Great Britain entered into an arrangement with France for a mutual right of search within certain seas, to which most of the other Powers acceded; and by the Ashburton Treaty (1842) with the United States provision was made for the joint maintenance of squadrons on the west coast of Africa. By all these measures the slave trade, so far as it was carried on under the flags of European nations or for the supply of their colonies, ceased to exist.

Anti-slavery Movement.—Meantime another and more radical reform had been in preparation and was already in progress, namely, the abolition of slavery itself in the foreign possessions of the several States of Europe. When the English slave trade

had been closed, it was found that the evils of the traffic, as still continued by several other nations, were greatly aggravated. In consequence of the activity of the British cruisers the traders made great efforts to carry as many slaves as possible in every voyage, and practised atrocities to get rid of the slaves when capture was imminent. It was, besides, the interest of the cruisers, who shared the price of the captured slave-ship, rather to allow the slaves to be taken on board than to prevent their being shipped at all. Thrice as great a number of negroes as before, it was said, was exported from Africa, and two-thirds of these were murdered on the high seas. It was found also that the abolition of the British slave trade did not lead to an improved treatment of the negroes in the West Indies. The slaves were overworked now that fresh supplies were stopped, and their numbers rapidly decreased. In 1807 there were in the West Indies 800,000; in 1830 they were reduced to 700,000. It became more and more evident that the evil could be stopped only by abolishing slavery altogether.

An appeal was made by Wilberforce in 1821 to Thomas Fowell Buxton to undertake the conduct of this new question in parliament. An anti-slavery society was established in 1823, the principal members of which, besides Wilberforce and Buxton, were Zachary Macaulay, Dr. Lushington and Lord Suffield. Buxton moved on May 5, 1823, that the House should take into consideration the state of slavery in the British colonies. The object he and his associates had then in view was gradual abolition by establishing something like a system of serfdom for existing slaves, and passing at the same time a measure emancipating all their children born after a certain day. Canning carried against Buxton and his friends a motion to the effect that the desired ameliorations in the condition and treatment of the slaves should be recommended by the home Government to the colonial legislatures, and enforced only in case of their resistance, direct action being taken in the single instance of Trinidad, which, being a Crown colony, had no legislature of its own. A well-conceived series of measures of reform was accordingly proposed to the colonial authorities. Thereupon a general outcry was raised by the planters at the acquiescence of the Government in the principles of the anti-slavery party. A vain attempt being made in Demerara to conceal from the knowledge of the slaves the arrival of the order in council, they became impressed with the idea that they had been set free, and accordingly refused to work, and, compulsion being resorted to, offered resistance. Martial law was proclaimed; the disturbances were repressed with great severity; and the treatment of the missionary Smith, which was taken up and handled with great ability by Brougham, awakened strong feeling in England against the planters. The question, however, made little progress in parliament for some years, though Buxton, William Smith, Lushington, Brougham, Mackintosh, Butterworth and Denman, with the aid of Z. Macaulay, James Stephen, and others, continued the struggle, only suspending it during a period allowed to the local legislatures for carrying into effect the measures expected from them. In 1828 the free people of colour in the colonies were placed on a footing of legal equality with their fellow-citizens. In 1830 the public began to be aroused to a serious prosecution of the main issue. It was becoming plain that the planters would take no steps tending to the future liberation of the slaves, and the leaders of the movement determined to urge the entire abolition of slavery at the earliest practicable period. The Government continued to hesitate and to press for mitigations of the existing system. At length in 1833 the Ministry of Earl Grey took the question in hand and carried the abolition with little difficulty, the measure passing the House of Commons on Aug. 7, 1833, and receiving the royal assent on the 28th. A sum of 20 millions sterling was voted as compensation to the planters. A system of apprenticeship for seven years was established as a transitional preparation for liberty. The slaves were bound to work for their masters during this period for three-fourths of the day, and were to be liable to corporal punishment if they did not give the due amount of labour. The master was, in return, to supply them with food and clothing. All children under six years of age were to be at once free, and provision was to be made for their religious and moral instruction. Many thought the postponement of emancipation unwise. Immediate liberation was carried out in Antigua, and public tranquillity was so far from being disturbed there that the Christmas of 1833 was the first for 20 years during which martial law was not proclaimed in order to preserve the peace. Notwithstanding protracted and strenuous opposition on the part of the Government, the House of Commons passed a resolution against the continuance of the transitional system. When this was done the local legislatures saw that the slaves would no longer work for the masters; they accordingly cut off two years of the indentured apprenticeship, and gave freedom to the slaves in Aug. 1838 instead of 1840.

The example of Great Britain was gradually followed by the other European States, and some American ones had already taken action of the same kind. The immediate emancipation of the slaves in the French colonies was decreed by the Provisional Government of 1848. In 1858 it was enacted that every slave belonging to a Portuguese subject should be free in 20 years from that date, a system of tutelage being established in the meantime. This law came into operation on April 29, 1878, and the status of slavery was thenceforth illegal throughout the Portuguese possessions. The Dutch emancipated their slaves in 1863. Several of the Spanish American States, on declaring their independence, had adopted measures for the discontinuance of slavery within their limits. It was abolished by a decree of the Mexican republic on Sept. 15, 1829. The Government of Buenos Aires enacted that all children born to slaves after Jan. 31, 1813, should be free; and in Colombia it was provided that those born after July 16, 1821, should be liberated on attaining their eighteenth year.

Three of the most important slave systems still remained in which no steps towards emancipation had been taken—those of the Southern United States, of Cuba and of Brazil.

Slavery in the United States.—Slavery was far from being approved in principle by the most eminent of the fathers of the American Union. Washington in his will provided for the emancipation of his own slaves; he said to Jefferson that it was "among his first wishes to see some plan adopted by which slavery in his country might be abolished by law," and again he wrote that to this subject his own suffrage should never be wanting. John Adams declared his abhorrence of the practice of slave-holding, and said that "every measure of prudence ought to be assumed for the eventual total extirpation of slavery from the United States." Franklin's opinions we have already indicated; and Madison, Hamilton and Patrick Henry all reprobated the principle of the system. Jefferson declared in regard to slavery, "I tremble for my country when I reflect that God is just." The last-named statesman, at the first Continental Congress after the evacuation by the British forces, proposed a draft ordinance (March 1, 1784) for the government of the North-west Territory, in which it was provided that "after the year 1800 there shall be neither slavery nor involuntary servitude in any of the said states, otherwise than in punishment of crime." This proviso, however, was lost; but in the ordinance of 1787 (July 13) for the government of the territory of the United States north-west of the Ohio river, which was introduced by Nathan Dane and probably drafted by Manasseh Cutler, slavery was forbidden in the territory. At the Convention of Philadelphia in 1787, where the constitution was drafted, the sentiments of the framers were against slavery; but South Carolina and Georgia insisted on its recognition as a condition of their joining the Union, and even an engagement for the mutual rendition of fugitive slaves was embodied in the Federal pact. The *words* "slave" and "slavery" were, however, excluded from the constitution, "because," as Madison says, "they did not choose to admit the right of property in man" in direct terms; and it was at the same time provided that Congress might interdict the foreign slave trade after the expiration of 20 years. It must not be forgotten that either before or soon after the formation of the Union the Northern States—beginning with Vermont in 1777, and ending with New Jersey in 1804—either abolished slavery or adopted

measures to effect its gradual abolition within their boundaries. But the principal operation of (at least) the latter change was simply to transfer Northern slaves to Southern markets.

We cannot follow in detail the several steps by which the slave power for a long time persistently increased its influence in the Union. The acquisition of Louisiana in 1803, which gave a new field for the growth of the slave power, though not made

THE SALE OF ESTATES, PICTURES AND SLAVES IN THE ROTUNDA, NEW ORLEANS; FROM A STEEL ENGRAVING BY J. M. STARLING EXECUTED AFTER THE PAINTING BY W. H. BROOKE

in its interest, the Missouri Compromise (1820), the annexation of Texas (1845), the Fugitive Slave Law (1850), the Kansas-Nebraska bill (1854), the Dred Scott decision (1857), the attempts to acquire Cuba (especially in 1854) and to reopen the foreign slave trade (1859–60), were the principal steps—only some of them successful—in its career of aggression. They roused a determined spirit of opposition, founded on deep-seated convictions. The pioneer of the more recent abolitionist movement was Benjamin Lundy (1789–1839). He was followed by William Lloyd Garrison (1805–79), Elijah P. Lovejoy (1802–37)—a martyr, if ever there was one—Wendell Phillips, Charles Sumner, John Brown (b. 1800, hanged 1859), all of whom were in their several ways leading apostles or promoters of the cause. The best intellect of America outside the region of practical politics has been on the anti-slavery side. William E. Channing, R. W. Emerson, the poets Bryant, Longfellow, pre-eminently Whittier and Whitman, have spoken on this theme with no uncertain sound. The South, and its partisans in the North, made desperate efforts to prevent the free expression of opinion respecting the institution, and even the Christian Churches in the slave States used their influence in favour of the maintenance of slavery. But in spite of every such effort opinion steadily grew. Public sentiment in the North was deeply stirred by the *Uncle Tom's Cabin* (1852) of Mrs. Harriet Beecher Stowe, which, as Senior said, under the disguise of a novel was really a pamphlet against the Fugitive Slave Law. It gradually became apparent that the question could not be settled without an armed conflict. The election of Abraham Lincoln as president in Nov. 1860 was the signal for the rising of the South. The North at first took arms simply to maintain the Union; but the farsighted politicians from the first, and soon the whole nation, saw that the real issue was the continued existence or the total abolition of slavery. (*See* UNITED STATES.)

The war was practically closed by the surrender at Appomattox (April 9, 1865), but already in 1862 slavery in the territories had been abolished by Congress; on Sept. 22 of the same year Lincoln (*q.v.*) had issued the preliminary emancipation proclamation, followed on Jan. 1, 1863, by the emancipation of all slaves in the States in arms against the Union; and in Dec. 1865 a constitutional amendment was ratified abolishing and for ever prohibiting slavery throughout the United States.

Cuba.—The Spanish slave code, promulgated in 1789, is admitted on all hands to have been very humane in its character; and, in consequence of this, after Trinidad had become an English possession, the anti-slavery party resisted—and successfully—the attempt of the planters (1811) to have the Spanish law in that island replaced by the British. But notwithstanding this mildness of the code, its provisions were habitually and glaringly violated in the colonies of Spain, and in Cuba particularly the conditions of slavery were very bad. The slave population of the island was estimated in 1792 at 84,000; in 1817 at 179,000; in 1827 at 286,000; and in 1843 at 436,000. An act was passed by the Spanish legislature in 1870, providing that every slave who had then passed, or should thereafter pass, the age of 60 should be at once free, and that all yet unborn children of slaves should also be free. The latter, however, were to be maintained at the expense of the proprietors up to their eighteenth year, and during that time to be kept, as apprentices, to such work as was suitable for their age. This was known as the Moret Law, having been carried through the house of representatives by Señor Moret y Prendergast, then minister for the colonies. By the census of 1867 there was in Cuba a total population of 1,370,211 persons, of whom 764,750 were whites and 605,461 black or coloured; and of the latter number 225,938 were free and 379,523 were slaves. In 1873 the Cubans roughly estimated the population at 1,500,000—of whom 500,000, or one-third, were slaves. In 1885, it was stated that "the institution was rapidly dying—that in a year, or at most two, slavery, even in its then mild form, would be extinct."

Brazil.—There was a convention between Great Britain and Brazil in 1826 for the abolition of the slave trade, but it was habitually violated in spite of the English cruisers. In 1830 the traffic was declared piracy by the emperor of Brazil. England asserted by the Aberdeen Act (1845) the right of seizing suspected craft in Brazilian waters. Yet by the connivance of the local administrative authorities 54,000 Africans continued to be annually imported. In 1850 the trade is said to have been decisively put down. The planters and mine proprietors cried out against this as a national calamity. The closing of the traffic made the labour of the slaves more severe, and led to the employment on the plantations of many who before had been engaged in domestic work; but the slavery of Brazil had always been lighter than that of the United States. On Sept. 28, 1871, the Brazilian chambers decreed that slavery should be abolished throughout the empire. Though existing slaves were to remain slaves still, with the exception of those possessed by the Government, who were liberated by the act, facilities for emancipation were given; and it was provided that all children born of female slaves after the day on which the law passed should be free. They were, however, bound to serve the owners of their mothers for a term of 21 years. A clause was inserted to the effect that a certain sum should be annually set aside from fines to aid each province in emancipating slaves by purchase. Seven years before the passing of this act the emperor, whose influence had always been exerted in favour of freedom, had liberated his private slaves, and many Brazilians after 1871 followed his example. Finally, in 1888 the chambers decreed the total abolition of slavery, some 700,000 persons being accordingly freed.

Disguised Slave Trade.—In the colonies of more than one European country, after the prohibition of the slave trade, attempts were made to replace it by a system of importing labourers of the inferior races under contracts for a somewhat lengthened term; and this was in several instances found to degenerate into a sort of legalized slave traffic. About 1867 we began to hear of a system of this kind which was in operation between the South Sea islands and New Caledonia and the white settlements in Fiji. It seems to have begun in really voluntary agreements; but for these the unscrupulous greed of the traders soon substituted methods of fraud and violence. The natives were decoyed into the labour ships under false pretences, and then detained by force; or they were seized on shore or in their canoes and carried on board. The nature of the engagements to go and work on the plantations was not fully explained to them, and they were hired for periods exceeding the legal term. The area of this trade was ere long further extended. In 1884 attention was drawn in a special degree to the Queensland traffic in Pacific Islanders by the

"Hopeful" trials, and a Government commission was appointed to enquire into the methods followed by labour ships in recruiting the natives of New Guinea, the Louisiade archipelago and the D'Entrecasteaux group of islands. The result of the investigations, during which nearly 500 witnesses were examined, was the disclosure of a system which in treachery and atrocity was little inferior to the old African slave trade. These shameful deeds made the islanders regard it as a duty to avenge their wrongs on any white men they could entice upon their shores. The bishop of Melanesia, John Coleridge Patteson, fell a victim to this retaliation in the island of Nukapu on Sept. 20, 1871.

It now remains to consider the slavery of primitive origin which has existed within recent times, or continues to exist, outside of the Western world.

Russian Serfdom.—In Russia, a country which had not the same historical antecedents with the Western nations, properly so called, and which is, in fact, more correctly classed as Eastern, whilst slavery had disappeared, serfdom was in force down to recent days. The rural population of that country, at the earliest period accessible to our enquiries, consisted of (1) slaves, (2) free agricultural labourers and (3) peasants proper, who were small farmers or cottiers and members of a commune. The sources of slavery were there, as elsewhere, capture in war, voluntary sale by poor freemen of themselves, sale of insolvent debtors and the action of the law in certain criminal cases. In the 18th century we find the distinction between the three classes named above effaced and all of them merged in the class of serfs, who were the property either of the landed proprietors or of the State. They were not even *adscripti glebae*, though forbidden to migrate; an imperial ukase of 1721 says, "the proprietors sell their peasants and domestic servants, not even in families, but one by one, like cattle." This practice, at first tacitly sanctioned by the Government, which received dues on the sales, was at length formally recognized by several imperial ukases. Peter the Great imposed a poll-tax on all the members of the rural population, making the proprietors responsible for the tax charged on their serfs; and the "free wandering people" who were not willing to enter the army were required to settle on the land either as members of a commune or as serfs of some proprietor.

The system of serfdom attained its fullest development in the reign of Catherine II. The serfs were bought, sold and given in presents, sometimes with the land, sometimes without it, sometimes in families and sometimes individually, sale by public auction being alone forbidden, as "unbecoming in a European state." The proprietors could transport without trial their unruly serfs to Siberia or send them to the mines for life, and those who presented complaints against their masters were punished with the knout and condemned to the mines. The first symptoms of a reaction appear in the reign of Paul (1796–1801). He issued an ukase that the serfs should not be forced to work for their masters more than three days in each week. There were several feeble attempts at further reform, and even abortive projects of emancipation, from the commencement of the 19th century. But no decisive measures were taken before the accession of Alexander II. (1855). That emperor, after the Crimean War, created a secret committee composed of the great officers of State, called the chief committee for peasant affairs, to study the subject of serf-emancipation. Of this body the grand-duke Constantine was an energetic member. To accelerate the proceedings of the committee advantage was taken of the following incident. In the Lithuanian provinces the relations of the masters and serfs were regulated in the time of Nicholas by what were called inventories. The nobles, dissatisfied with these, now sought to have them revised. The Government interpreted the application as implying a wish for the abolition of serfdom, and issued a rescript authorizing the formation of committees to prepare definite proposals for a gradual emancipation. A circular was soon after sent to the governors and marshals of the nobility all over Russia proper, informing them of this desire of the Lithuanian nobles, and setting out the fundamental principles which should be observed "if the nobles of the provinces should express a similar desire." Public opinion strongly favoured the projected reform; and even the masters who were opposed to it saw that, if the operation became necessary, it would be more safely for their interests entrusted to the nobles than to the bureaucracy. Accordingly during 1858 a committee was created in nearly every province in which serfdom existed. From the schemes prepared by these committees, a general plan had to be elaborated, and the Government appointed a special imperial commission for this purpose.

The plan was formed, and, in spite of some opposition from the nobles, which was suppressed, it became law, and serfdom was abolished (Feb. 19–March 3, 1861). (*See* RUSSIA.) The total number of serfs belonging to proprietors at the time of the emancipation was 21,625,609, of whom 20,158,231 were peasant serfs and 1,467,378 domestic serfs. This number does not include the State serfs, who formed about one-half of the rural population. Their position had been better, as a rule, than that of the serfs on private estates; it might, indeed, R. D. M. Wallace says, be regarded as "an intermediate position between serfage and freedom." Amongst them were the serfs on the lands formerly belonging to the Church, which had been secularized and transformed into State demesnes by Catherine II. There were also serfs on the apanages affected to the use of the imperial family; these amounted to nearly three and a half millions. Thus by the law of 1861 more than 40 millions of serfs were emancipated.

(J. K. I.)

MOHAMMEDAN SLAVERY

The Koran, like the Mosaic code, recognizes slavery, and lays down regulations as to the treatment of slaves. These regulations have been interpreted in a more, or in a less, humane spirit by the different sects of Islam (*q.v.*) and the treatment accorded may also vary by custom and tradition in different countries, and in the administration of the law by individual kadis. In the larger and more modernized Mohammedan States, the slave trade has long been declared illegal. The Ottoman Porte was a signatory to the Berlin Act of 1885 (*see* p. 785) and enacted a law in 1889 declaring the illegality of the slave trade. Persia and Zanzibar joined her as signatories of the Brussels Act of 1890. In some of the minor Mohammedan States, however, as, for instance, the Hedjaz, the traffic has persisted up to the present time.

The Koran enjoins the good treatment of the slave, and manumission is encouraged as an act of piety. The child of a slave concubine by her master is free-born, and the mother is usually freed also. The slave "born in the house" is generally regarded as a member of the family and to sell such a slave, except for incorrigible misconduct, would be condemned by public opinion. The favourite slaves of a ruler often held high office as confidential advisers, as administrators of provinces, or as leaders in the army. The master is bound to care for his slave in sickness and old age, and to maintain his wife and family. Facilities were afforded for self-redemption and for ransom. The predial slave, on the other hand, gradually developed into a serf *adscriptus glebae*. He would usually be allowed to retain part of the usufruct of the estate for himself, or be permitted to work for one or more days in the week on his private holding.

Slavery in Africa.—After the trade in slaves to America and the West Indies from West Africa had been declared illegal, in the early part of the 19th century, a very considerable smuggling traffic was still carried on, until slavery itself was abolished in America after the Civil War. Strenuous efforts were made by Great Britain to suppress this traffic by war-ships at sea, and in 1861 Lagos was acquired as a depôt for the naval vessels employed on this service. The term "slave trade" which had hitherto been used to refer exclusively to this traffic, now bore a new meaning as referring either to the surreptitious export of slaves to Arabia, Persia and the Red sea littoral, from the north-eastern and eastern coasts of the Continent, or to the internal slave trade to satisfy the demand of the Mohammedan States in the north and west and Zanzibar, as well as that of the negro kingdoms of Uganda, Benin, Dahomey, etc. Of the slaves required by the latter, large numbers were sacrificed in Pagan ceremonials, and on the death of the king, or of their owners.

The existence of this internal slave trade first became known to Europe from the reports of the early explorers, in the middle

of the 19th century—more especially from the accounts of Dr. Livingstone, Sir Samuel Baker and Dr. Barth. The trade in the north is thus described by Dr. Ingram.

The central Sudan appeared to be one vast hunting-ground. Captives were brought thence to the slave market of Kuka in Bornu, where, after being bought by dealers, they were, to the number of about 10,000 annually, marched across the Sahara to Murzuk in Fezzan, from which place they were distributed to the northern and eastern Mediterranean coasts. Their sufferings on the route were dreadful; many succumbed and were abandoned. Rohlfs informs us that "any one who did not know the way" by which the caravans passed "would only have to follow the bones which lie right and left of the track." Negroes were also brought to Morocco from the western Sudan and from Timbuktu. The centre of the traffic in Morocco was Sidi Hamed ibn Musa, seven days' journey south of Mogador, where a great yearly fair was held. The slaves were forwarded thence in gangs to different towns, especially to Marrakesh, Fez and Mequinez. About 4,000 were thus annually imported, and an *ad valorem* duty was levied by the sultan, which produced about £4,800 of annual revenue. The control now exercised by the French over the greater part of the western Sudan has deprived Morocco of its chief sources of supply. The basin of the Upper Nile, extending to the great lakes, was another region infested by the slave trade; the slaves were either smuggled into Egypt or sent by the Red sea to Turkey. The khedive Ismail in 1869 appointed Sir Samuel Baker to the command of a large force with which he was "to strike a direct blow at the slave trade in its distant nest." The work begun by him was continued by Col. C. G. Gordon (1874–79), but under the Mahdi and the Khalifa the slave trade was revived. Since the reconquest of the eastern Sudan by an Anglo-Egyptian force in 1898 effective measures have been taken to suppress slave raiding and as far as possible slavery itself. The conquest of the central Sudan States by France—completed in 1910 by the subjugation on Wadai—has practically ended the caravan trade in slaves across the Sahara.

Benghazi in Cyrenaïca long remained a port for the surreptitious export of slaves, but the assertion of Italian sovereignty over Tripoli and its hinterland has effectually killed the traffic.

The Berlin and Brussels Acts.—The export from Zanzibar to Arabia and the Persian gulf persisted till the close of the century, and it was mainly with a view to the suppression of this traffic that a conference of the Powers signatory to the Berlin Act (to whom were added Persia, Zanzibar and the Congo Free State) was summoned at the instance of Queen Victoria to assemble at Brussels in 1889. The Berlin Conference of 1885 had been primarily concerned with the political and commercial relations of the Powers which were engaged in the "scramble for Africa." Its scope was limited to "the Conventional basin of the Congo," and in only two of its 38 articles was the subject of slavery referred to. In these (articles 6 and 9) the "Powers exercising sovereign rights or influence" within this zone, pledged themselves "to help in suppressing slavery and the slave trade."

The Brussels Conference, on the other hand, was solely directed to "putting an end to the crimes and devastations engendered by the traffic in African slaves, protecting effectively the aboriginal populations of Africa, and insuring for that vast continent the benefits of peace and civilization." It was recognized that "the maritime zone in which the slave trade still exists" had shifted from the west to the east coast of Africa, and that zone, in which special regulations as to rights of search, etc., were laid down, was defined as extending "between the coasts of the Indian ocean, including those of the Persian gulf, and of the Red sea from Beluchistan to Quillimane" a port in Portuguese East Africa S. lat. 18°, and thence southwards to S. lat. 26° and eastwards so as to include Madagascar. The general act, prefaced by the words "In the name of Almighty God," dealt in its 100 articles with measures for the suppression of the slave trade by sea and land, the restriction of the import of arms of precision, and ammunition between lat. 20° N. and lat. 22° S. of spirituous liquor with Africa. It marked a new era in the international recognition of the responsibilities of the civilized Powers towards the subject races. As early as 1873 Sir John Kirk, British consul-general in Zanzibar, had succeeded in inducing the sultan to declare that the export of slaves from the mainland was illegal, and in 1876 an edict was issued prohibiting their arrival at the coast from the interior. The edicts were, however, disregarded. For over half a century Great Britain had maintained a squadron in East-African waters for the suppression of the trade, but in 1883 H.M.S. "London," and her fleet of small vessels, adapted for pursuing the slave-dhows into the creeks and shallow waters, was withdrawn, and three vice-consuls (one in Lake Nyasa and two on the coast) were substituted. Naval action had proved wholly inadequate, and very costly both in lives and money, but British war-vessels continued to capture slave-dhows. Nor were the pledges of the signatory Powers to the Berlin Act, productive of any tangible results, for it was estimated that not 5% of the slaves exported were rescued.

The partition of Africa between the European Powers which took place at this time, rendered obsolete the provisions of the Brussels Act in so far as they related to the establishment of cities of refuge for fugitive slaves, armed vessels on the great lakes and fortified posts. With the assumption of control by Europe in Africa, the overseas slave trade rapidly came to an end except as regards Abyssinia, the only country which maintained its independence under its traditional rulers. It was in evidence before the slavery committee of the League of Nations in 1926 (*see* p. 786) that a considerable traffic in slaves from that country to the Hedjaz (Arabia) was still carried on, her Government being powerless to stop it.

Internal Slave Trade.—The second phase of the slave trade, viz., the raids for slaves to supply the internal demand from Mohammedan States and pagan kingdoms in Africa, was equally doomed to extinction by the advent of settled administration; but it did not disappear without a struggle. In the eastern Sudan the conquests of Baker and Gordon over the Turco-Egyptian slave raiders had been effaced by the sanguinary rule of the Mahdi, and it was not until he in turn had been conquered by Kitchener in 1898, that effective control could be exercised.

The consolidation of French rule in the north, and the final defeat of Samory and other powerful Mohammedan potentates in the west, put an end to the organized traffic in slaves, though as late as 1926 parties of tribesmen in the desert still defied authority. In Nigeria the power of the Mohammedan rulers who annually employed large armies in raiding for slaves, and had depopulated great regions, was broken in 1902–3, and slave-raiding was stopped. In the Congo region King Leopold declared war on Tippoo Tib, Rumaliza and other notable east-coast Arabs who had settled there and had become powerful despots, practically independent of Zanzibar. They were crushed after a severe struggle. In Nyasaland—a favourite hunting-ground of the Zanzibar slavers—a stand had been made by a Scottish trading company, and when control was assumed by Great Britain, the raids of Mlozi, Jumbe and other noted slavers were suppressed. The advent of Europe was probably only just in time to anticipate and prevent a Mohammedan domination in central Africa.

The Status of Slavery.—Before the close of the first decade of the 20th century a more or less effective administration had been established throughout Africa, under European control, except in Abyssinia and Liberia. The public opinion of the civilized world, no longer limited its reprobation to the slave trade but now condemned the institution of slavery—especially of slave-dealing—and the Powers in control in Africa took steps to suppress it with varying degrees of thoroughness. France boldly decreed compulsory emancipation in French West Africa, but was confronted with such widespread unrest in consequence that she was compelled to adopt more gradual measures. In the Portuguese possessions the prohibitions are understood to have been largely ineffective, and the Government itself was at one time accused of conniving at a system differing little from slavery in order to procure labour for the plantations of San Thomé and Principe. Germany declared emancipation from a prospective date.

Great Britain, taught by her experience in the West Indies and in India, recognized the evils attendant on compulsory emancipa-

tion, and adopted in most of her African dependencies the alternative measure of abolishing the legal status of slavery—as the East India company had done with success in 1843. She recognized that in many cases, especially among communities which had adopted the Mohammedan faith, or a Christianity based on the law of the Pentateuch as in Abyssinia, the institution had become so intimately interwoven with the social fabric, that sudden and enforced emancipation would bring ruin and misery to the slaves no less than to their owners.

If the legal status of slavery be abolished no court of law can recognize any rights based on the claim of any person to property in the person of another. Every slave can assert his freedom without any ransom or formality, and an owner is as liable to process of law for attempting to detain a slave against his will, or to capture a runaway as though he were free-born. On the other hand, it is not a crime for a master to retain a slave if both desire to remain in that relationship. It is permissive as contrasted with compulsory emancipation. This method was eminently successful in the Gold Coast and in Nigeria. It was not, however, adopted in Sierra Leone until Jan. 1, 1928, then it is estimated that about 200,000 slaves were by this method enabled to assert their freedom. Local ordinances have at the same time enacted that the acquisition of new slaves and all dealings in slaves are a penal offence, and that all children born after the date of the ordinance are free-born.

The Convention of 1919.—The aspirations of the Berlin and Brussels Acts had been limited to the suppression of the slave trade and had not attempted to deal with the institution of slavery. In Sept. 1919 a new convention was concluded at St. Germains by which the signatories pledged themselves "to endeavour to secure the complete suppression of slavery in all its forms" (art. 11). A new departure was thus inaugurated, and for the first time not only was the suppression of slavery as a social institution agreed upon in an international convention, but the fact that conditions of servitude might exist, which were tantamount to slavery gained international recognition; a recognition which was more fully accorded in the terms of the mandates which were soon after granted to the Powers which accepted the control of the former colonies of Germany and Turkey. This convention superseded the Berlin and Brussels Acts so far as its signatories (the Allies against the Central European Powers in the World War) were concerned. It dealt with the varied matters included in those acts but the liquor traffic and the arms traffic were relegated to separate conventions, while slavery and the slave trade occupied a single clause. Some doubt appeared to exist as to the wisdom of the cancellation of several of the slavery clauses of the Brussels Act, and as to the position of its remaining signatories. Advantage was, therefore, taken of the admission of Abyssinia to membership of the League of Nations—a country in which slavery was still a legal institution, and in which slave raiding and the slave trade had till recently been carried on, and were alleged to be still existing—to reopen the question as a matter of international concern.

Committee of 1924 and Convention of 1926.—A committee appointed by the League to investigate the subject met in July 1924 and again in the following year. It recommended *inter alia* a new convention—not confined to Africa—to which the adherence of all States whether members of the League or not should be invited. This proposal was accepted, and the British Government submitted a draft convention. All the members of the League and also Afghanistan, Ecuador, Egypt, Germany, Mexico, the Sudan, Turkey and the United States were invited to submit any suggestions, and "to assist one another forthwith in the abolition of the slave trade, slavery and conditions analogous thereto by all practicable means."

The "analogous conditions" says the official report "are intended to include all forms of debt slavery—the enslaving of persons disguised as the adoption of children, and the acquisition of girls by purchase disguised as payment of dowry, etc."—matters to which attention had been drawn in the committee's report. The convention which embodied the highest minimum standard to which it was anticipated that general acceptance could be secured, was ratified by 15 States, viz., Australia, Austria, the British Empire, Bulgaria, Denmark, Haiti, Hungary, India, Latvia, New Zealand, Norway, Portugal, Spain, the Sudan and South Africa. Belgium, France, Germany, Italy, and the Netherlands expected that they would be able to ratify at a later date. India made reservations in regard to the unadministered districts on her frontiers, and the territories of Indian rulers under the suzerainty of the British Crown.

Forced Labour.—"The convention (says the report) deals for the first time in international agreements with the question of forced labour." Art. v. is as follows:

"The High Contracting Parties recognize that recourse to compulsory or forced labour may have grave consequences and undertake, each in respect of the territories placed under its sovereignty, jurisdiction, protection, suzerainty or tutelage, to take all necessary measures to prevent compulsory or forced labour from developing into conditions analogous to slavery.

It is agreed that:

(1) Subject to the transitional provisions laid down in paragraph (2) below, compulsory or forced labour may only be exacted for public purposes.

(2) In territories in which compulsory or forced labour for other than public purposes still survives, the High Contracting Parties shall endeavour progressively and as soon as possible to put an end to the practice. So long as such forced or compulsory labour exists, this labour shall invariably be of an exceptional character, shall always receive adequate remuneration, and shall not involve the removal of the labourers from their usual place of residence.

(3) In all cases, the responsibility for any recourse to compulsory or forced labour shall rest with the competent central authorities of the territory concerned."

The terms used are a compromise between opposing views, and it was agreed that the question should be referred to a "committee of experts" to be summoned by the International Labour Office. The committee met in July 1927 and has not yet submitted its report. There is probably a consensus of opinion that in certain cases a State may find itself under the necessity of compelling labour for essential public works or services. There is also probably a predominant opinion that such labour should be fairly remunerated, though some hold the view that if compulsory labour is imposed under the guise of a tax—as a fiscal measure—it need not be restricted to urgent public services, and, of course, would not be remunerated—as the Central African mandates require. The second principle to be determined is whether it is permissible in any circumstances to use compulsion for the supply of labour, even though paid, in enterprises conducted for private profit. Abuses of the system known in South America as "peonage" fall under this category, by which labourers become involved in debt which they can never repay, and so become slaves for life. The Slavery Commission pointed out that this system merits particular condemnation when an alien employer deliberately adopts measures to secure by such means the life-long servitude of an ignorant and unsuspicious peasantry.

Slavery in Asia.—Following the adoption of the convention by the League of Nations several notable instances of the liberation of slaves have occurred. H.H. the Maharaj. of Nepal issued a very striking appeal to his people in Nov. 1924 for the liberation of the 51,419 slaves in his kingdom, which was completely successful. Compensation on a fixed scale was paid to those who claimed it. The governor of Burma despatched a series of expeditions into the unadministered and unexplored districts on the frontiers inhabited by the Naga tribes, and effected the release of all slaves. From Abyssinia it is reported that enlightened regulations have been framed in regard to slave raiding, slave trading and slavery and that many slaves have been set free. Since Abyssinia was admitted to membership of the League in Sept. 1923 on condition of reform in these matters, it becomes incumbent on the League to verify these reports—the more so that it was in evidence before the Slavery Committee in 1926 that a considerable traffic in slaves existed chiefly from Abyssinia to the Hedjaz (Arabia) and at the present time (1928) the Sudan Government has found it necessary to establish a sanctuary near

Kassala, and other "refugee colonies" for slaves who have escaped from Abyssinia.

From this brief outline it is evident that the standards and aspirations of the world after the World War show a fuller appreciation of the true interests of the "backward races" than was possible a couple of decades ago, and an intention to abolish finally the status of slavery throughout the world. SLAVERY CONVENTION. The Slavery Convention of the League of Nations, approved and adopted by the seventh Assembly in 1926 for submission to, and ratification by, the States Members of the League, had as its object to complete and extend the work of the Brussels Act and to give practical effect to the Convention of St. Germain. The Powers bind themselves to bring about "progressively and as soon as possible the complete abolition of slavery in all its forms," which include debt slavery, the so-called adoption of children, etc. The parties undertake to suppress the slave trade by sea, and to negotiate a Convention on the trade in slaves; also, to prevent forced labour developing into conditions analogous to slavery. Such labour may only be exacted for public purposes, apart from purely transitory arrangements. So long as forced labour for any other than public services survives, it is invariably to be of an exceptional character, to receive adequate remuneration, and not involve the labourers' removal from their homes. At the 1927 Assembly every Colonial Power agreed to ratify the Convention at an early date. (T. Bu.)

SLAVONIC LANGUAGES. The Slavonic languages belong to the Eastern or Satem division of the Indo-European family, and are very closely connected with the Baltic group, which embraces Lithuanian, Lettish and the now extinct Old Prussian. The phonetic and morphological affinities between the two groups are so striking that many scholars have postulated a Balto-Slavonic unity on a par with that existing between Indian and Iranian. Although a unity of this character is now disputed, largely because of the differences in vocabulary, verbal structure and formative elements employed, the common innovations and general parallelism of development make it probable that the two ethnic groups lived in close contiguity and influenced each other long after they had become separated from their original neighbours. Their contact probably persisted over a very long period, but a separation must have occurred centuries before the Christian era, each group thenceforward developing along its own lines. To-day the Slavs and the Balts are again in partial contact, but the influence each exercises over the other is almost wholly on the side of the Slavs, whose northern languages have affected the vocabulary of the Balts. Slavonic has considerably less in common with Teutonic, and the resemblances which may be observed in vocabulary are for the most part due to the adoption by Slavonic of Teutonic words which, with the objects of culture they denoted, became known to the less civilised Slavs.

With one branch of the Iranians, the Sarmatians, the Slavs remained in touch until after the Christian era and obtained from them some words, e.g., *Bogŭ*, *cf.* Persian *Baga* (god). The alteration of an original *s* after *i, u, r* and *k,* which is common to Slavonic and Iranian, is on a different footing from loans of vocabulary: it is a sound law which can be traced also in Indian and Baltic, and so argues an early differentiation of I.E. rather than an independent, common development of Slavonic and Iranian.

After the Baltic group had ceased to be connected with the Slavonic, we must imagine a long period when Slavonic was a bundle of dialects, showing in embryo some of the peculiarities of the future languages, but on the whole so much alike that we may say that a form occurring in one dialect was also common to the others. This stage may be called Common Slavonic (C.S.). Except for the few cases where Old Bulgarian (O.B.) has either definitely South Slavonic characteristics or peculiar characteristics of its own, as written down by Cyril it represents with great completeness Common Slavonic at the moment of its falling apart. In one respect, however, O.B. lends us no assistance for determining the pronunciation of a C.S. word: we have no direct means of ascertaining either the original word intonation or the sentence melody.

The period of time which elapsed until C.S. was formed out of I.E. is so long that great changes—the details of which can only be surmised—necessarily arose, but it is indicative of the absence of foreign cultural influences that there has not been any such discontinuity of linguistic tradition as has occurred in many other I.E. groups. The violent upheavals and ethnic amalgamations which have left so profound a mark on Teutonic, Italic and Greek, are lacking in Slavonic. The I.E. vocabulary continued to satisfy most needs of Slav speakers; losses were made good by new words

formed after the old models and with the help of the old methods of derivation the type of accentuation suffered no radical changes, and indeed all innovations were evolutionary rather than revolutionary. The Slav languages, even to-day, conform closely to the primitive type and present an uncommonly archaic aspect. They have progressed far less and have remained far nearer to each other than the Romance or Teutonic languages. Such differences as separate French from Spanish or Rumanian are quite unknown; with some preliminary practice a peasant from Slovakia, which of course enjoys the benefit of a central position in the Slavonic territory, is understood by a Slav from any other country.

Among the ruling principles which have determined the physiognomy of Slavonic speech are: the rigorous division of the vowels into a prepalatal and a postpalatal series—this having big consequences for the subsequent fate of the preceding consonants—and a system of word division which tolerated only open syllables. Except in initial position, the I.E. vowels generally underwent slight changes, but the loss of labialisation suffered by long *u*, and the levelling of short *o* and *a* under *ŏ*, are characteristically Slavonic. The change of short *ŭ* and *ĭ*, which were not kept distinct everywhere, led to great alterations in the syllabic character of words and has tended, especially in Polish, to produce difficult consonantal groups. The distinction between voiced and voiceless sounds continued without interruption, and the nasal and liquid consonants, when initial or intervocalic, also persisted unchanged. Numerous sibilants (of the type of English wi*tch* and wi*ts*) arose at different periods, after the separation from Baltic but before our earliest Slavonic records, and the combination of vowels with following nasal or liquid consonants, when the latter were followed by a consonant, conditioned the formation of nasal vowels. To sum up, the general persistence of vowels in positions where vowels already existed in an I.E. word, and the conservative behaviour of consonants make it possible to recognize, with a minimum knowledge of historical grammar, the fundamental connection of a Slavonic word with its corresponding I.E. prototype. *Nebese,* compared with its Greek equivalent *νέφους* is much the nearer to the form postulated for Indo-European. The complicated phenomena of vowel gradation (Ablaut), as presented by Slavonic, in the main answer to the Indo-European.

Morphology.—In the sphere of morphology the Slavonic languages have preserved much, but have also introduced many simplifications. Nouns have three genders, three numbers in O.B., Slovene and Sorb (other tongues have more or less numerous traces of the Dual) and, except in Bulgarian, seven cases—Nom., Voc. (not in Great Russian or Slovene), Acc., Gen., Dat., Instrumental and Locative. The Ablative has coincided with the Genitive.

The *-o-*, *-ā-* and *-i-* declensions have gained at the expense of the consonantal and *-ŭ-* stems, and phonetic or analogical change has caused many cases to coincide, especially in the dual. The adjective, when definite, receives a pronominal element, at first clearly distinguishable, but later unrecognizably merged in the body of the word. There is neither a definite nor an indefinite article. Of the two I.E. types of inflexion, the thematic and the athematic, the latter has lost ground to the former, and the *-s-* aorist early tended to be lost in favour of a more transparent thematic formation.

The verb, indeed, has lost most of the I.E. voices, moods and tenses. The passive only survives in the present and past participles; of the finite moods there are left but the indicative and optative (nearly always used as an imperative); its only old tenses are the present and the aorist, to which it has added an imperfect of its own. There is an infinitive and a supine, both representing cases of an original verbal noun. Of active participles there are a present and a past and a second past participle in *-l-* (*cf.* Latin *bibulus*), used in making compound tenses. The verb has two stems; from the present are formed the indicative present and imperfect, the imperative and the active and passive present participles. All other forms are based upon the infinitive stem. The primary personal endings continue those of I.E. in a form recognizable to-day, but the secondary endings have lost their final consonants by phonetic change. The aorist has no augment and has been replaced by a periphrastic formation with the *-l-* participle in nearly all the modern languages. The past participle passive is formed with *-t-* or *-n-*. (*Cf.* Latin *plenus* and *pletus.*) The I.E. future having been lost, futurity is expressed by auxiliary verbs as in the Romance languages. The passive is expressed either by the use of the passive participles or by the reflexive pronoun, which can refer to the 1st and 2nd persons as well as to the 3rd.

Syntax.—Syntactic peculiarities of the Slavonic languages are a tendency to use the genitive, under certain circumstances, instead of the accusative (which has often coincided in form with the nominative); the use of the genitive for the accusative or even nominative in negative clauses; the dative absolute and the dative as subject to an infinitive; the instrumental instead of the nominative as a predicate, and, in *oratio obliqua,* the preservation of the tense of the original statement, instead of our way of throwing it into the past.

In the use of the verbs the development of "aspects" makes up for the few tenses. All verbs fall into two great divisions, *imperfective,* which express the continuance of an action, without regard to its beginning and end, and *perfective,* which express the points of beginning or ending. The continuance of an action may be unbroken or may consist in a succession of like acts. Accordingly, imperfective verbs are divided into *durative* and *iterative,* and again the repeated acts expressed by the iterative can either, each of them, be momentaneous, or each have some continuance, or can even express the occasional repetition of groups of momentaneous actions.

Among perfective verbs we have (1) *momentaneous,* expressing action which has no continuance, (2) *finitive,* expressing not the continuance of the action, though there has been that, but its end or completion, and (3) *ingressive,* expressing the moment of beginning an action.

As perfective verbs do not express continuance, an idea implied in the present, they do not need a present form, which is therefore used for perfective futures. Similarly the aorist is usual with perfective, but the imperfect with imperfective verbs. If a durative verb is compounded with a preposition, it becomes perfective. (*Cf.* English "sit," which is usually imperfective, with "sit down.")

Some Slavonic languages (notably Czech) have extended the possibilities of the aspects still further, but others, *e.g.*, Slovene, have made simplifications and permit the union of a perfective infinitive with an auxiliary, to form the future.

The formation of the sentence is not naturally complicated, and the word order is almost as free as in the classical languages, but Slavonic has in times past been largely influenced by Greek, Latin and German with their involved periods; latterly there has been a tendency to follow the simpler models of French and English.

Such being the Slavonic languages as a whole and regarded in their relationship to I.E., they may now be considered in their relationship to each other. Some account of each language will be found under its name.

Divisions.—The Slavonic languages are usually divided into three groups:

(1) The Western, comprising Polabian, Polish, Sorb or Wendish, and Czechoslovak. Polabian, which was the language of the Slavs of the Elbe (*Laba* is the Slavonic name for the Elbe), is now dead, its speakers having been Germanized in the course of the last thousand years. It was spoken in the South-Eastern part of Holstein, in Mecklenburg and on the island of Rügen, in part of Hanover (where the last remnants of the language survived until the 18th century), in the northern part of Brandenburg and in Pomerania. Closely connected with Polabian is Polish, which has an old literary tradition. Kašube, spoken in the neighbourhood of Danzig, presents archaic features in the accentuation, and in its earlier form was the connecting link with Polabian. Sorb or Wendish, which is spoken on both sides of the Spree in Upper and Lower Lusatia, and is divided, according to the dialect used, into Upper and Lower Sorb, formerly occu-

pied a much larger area and formed a natural transition to Polabian, Polish and Czech. Czech and Slovak—really two separate but closely related literary languages, although the compound word Czechoslovak to express either one or both languages is winning acceptance—are spoken respectively in Bohemia and Slovakia. The dialects of Moravia bridge the two languages.

(2) The Eastern, comprising Great Russian, the scientific name of the language generally known as Russian simply; Little Russian, now usually called Ukrainian and formerly also called Ruthenian in those parts of old Austro-Hungary where it was spoken; and White Russian, which has recently been elevated into a literary language.

(3) The Southern, comprising Slovene, Serbo-Croat and Bulgarian. The Croat spoken near Zagreb (the so-called *kaj* dialect) is a transition dialect between Slovene and literary Serbo-Croat. Serb and Croat are identical languages, but the former is written in the Cyrillic and the latter in the Latin alphabet. The Macedonian dialects represent a midway stage between Serb and Bulgarian, the last of the Southern group. The language of the first Slavonic translators was an old form of Macedonian Bulgarian and, because of certain phonetic resemblances to Bulgarian, is called either Old Bulgarian or Old (Church) Slavonic, and is here abbreviated as O.B.

Without entering into the peculiarities of each Slavonic language, it may be said that on the whole the geographical classification of the Slavs is justified linguistically, though the lines of division are rendered less definite by the approximation of the languages which are contiguous in area, the special characteristics of each group being generally represented in dialects of the others, if not in the written languages. Also, within historic time, certain languages have influenced others through literary and political intercourse. O.B. has influenced all the Orthodox Slavs and the Croats, so that Russian is full of O.B. forms, pronounced *à la Russe*. Czech has almost overshadowed Slovak and early afforded literary models to Polish. Polish has overshadowed Kašube and much influenced Little and White Russian, and Great Russian in a less degree. Russian has in its turn supplied modern Bulgarian with a model. Again, other tongues have contributed; in Common Slavonic Germanic loan words already occur, and others have followed at various periods, especially in Czech, Polish and Slovene. Bulgarian and Serbo-Croat have incorporated many Turkish words; Russian added many Eastern words in the Tatar period and has absorbed the common vocabulary of Western civilisation since the time of Peter the Great (this tendency has been accentuated under the Bolshevik *régime*); but on the whole, though the Slav easily takes to a fresh language, he has kept his own free from any great admixture. The various Slavonic languages are treated under the national headings. But for Bulgarian *see* OLD SLAVONIC.

BIBLIOGRAPHY.—*Enciklopedija slavjanskoj filologii*, in particular the first volume, *Istorija slav. fil.*, by V. Jagić (1910); A. Meillet, *Le Slave Commun* (1924); V. Vondrák, *Vergleichende Slavische Grammatik* (2nd edition, Göttingen, 1924); E. E. Mikkola, *Urslavische Grammatik* (Heidelberg, 1913); R. Trautmann, *Baltisch-Slavisches Wörterbuch* (Göttingen, 1923); E. Berneker, *Slavisches etymologisches Wörterbuch* (only 1st volume is completed; reference must therefore be made to the earlier work of F. Miklosich, *Etym. Wörterbuch d. slav. Sprachen*, Vienna, 1886); O. Broch, *Slavische Phonetik* (Heidelberg, 1911) gives a good account of the pronunciation of all the Slavonic languages. The *Archiv für slavische Philologie* (Berlin) and the *Revue des études slaves* (Paris) will provide any further bibliography required. Some general information will also be found in the *Slavonic Review* (London, 1922 *seq.*). (N. B. J.)

SLAVS. The Slavs are the most numerous linguistic group in Europe. Outside Europe there are the Russians in Siberia, a mere extension of the main body, and emigrants in America.

Divisions and Distribution.—The Slavs are divided geographically and linguistically into three main groups, Eastern, North-Western and Southern.

The Russians form the Eastern group. They hold all the East European plain from the 27th meridian to the Urals, the Finnish and Tatar tribes making up but a small proportion of the population: to the east they stretch into central Siberia and thence in narrow bands along the rivers all the way to the Pacific; on the west the Ruthenians of Galicia form a wedge between the Poles and the Magyars and almost touch the 20th meridian.

The North-Western group includes the Poles, in the basin of the Vistula; the Kashubes on the coast north-west of Danzig; the High and Low Sorbs or Wends in Lusatia, Slavs completely surrounded by Germans, the Czechs and their eastern neighbours, the Moravians, now included in Czechoslovakia. Connecting up Ruthenians, Poles and Moravians, but most closely akin to the latter, are the Slovaks (*q.v.*). The now teutonized Slavs of central Germany, once stretched as far to the north-west as Rügen and Holstein and to the south-west to the Saale. They are generally called Polabs (*q.v.*), or Slavs on the Elbe.

The Southern Slavs, Slovenes (*q.v.*), Serbo-Croats and Bulgarians are cut off from the main body by the Germans of Austria proper and the Magyars, both of whom occupy soil once Slavonic, and have absorbed much Slavonic blood, and by the Rumanians of Transylvania and the Lower Danube. These Slavs occupy the main mass of the Balkan Peninsula downwards from the Julian Alps and the line of the Muhr, Drave and Danube. North of this all three races have considerable settlements in southern Hungary. Their southern boundary is very ill-defined, various nationalities being closely intermingled. To the south-west the Slavs march with the Albanians, to the south-east with the Turks, and to the south and along the Aegean coasts they have the Greeks as neighbours.

Linguistic Divisions.—Linguistically the separation is not sharp, though it coincides with the new political frontiers. Roughly speaking, the eastern half of the peninsula is held by the Bulgarians, the western half by the Serbo-Croats. This is the most divided of the Slavonic races; its members profess three forms of religion and use three alphabets—the Serbs and Bosnians being mostly Orthodox and using the Cyrillic alphabet, but including many Muslims; the Croats being Roman Catholics, writing with Latin letters; and the Dalmatians also Roman Catholics, but using, some of them, the ancient Glagolitic script for their Slavonic liturgy. The language also falls into three dialects independent of the religions, and across these lines run the frontiers of the political divisions. In the extreme north-west, in Carniola, in the southern parts of Styria and Carinthia, and over the Italian border in the province of Udine and the Vale of Resia live the Slovenes, much divided dialectically. Between the Slovenes and the Croats there are transition dialects, and about 1840 there was an attempt (Illyrism) to establish a common literary language. In Macedonia and along the border are special varieties of Bulgarian, some of which approach Serbian. Akin to the Macedonians were the Slavs, who once occupied the whole of Greece and left traces in the place-names, though they long ago disappeared among the older population. Akin to the Slovenes were the old inhabitants of Austria and south-west Hungary before the intrusion of the Germans and Magyars.

History.—This distribution of the Slavs can be accounted for historically. Though traditions (*e.g.*, the first Russian chronicle of Pseudo-Nestor) bring them from the basin of the Danube, most evidence goes to show that when they formed one people they were settled to the north-east of the Carpathians in the basins of the Vistula, Pripet and Upper Dněstr (Dniester). To the N. they had their nearest relatives, the ancestors of the Baltic tribes, Prussians, Lithuanians and Letts; to the E. Finns; to the S.E. the Iranian population of the Steppes of Scythia (*q.v.*); to the S.W., on the other side of the Carpathians, various Thracian tribes; to the N.W. the Germans; between the Germans and Thracians they seem to have had some contact with the Celts, but at first the Illyrians, Greeks and Italians probably came between. This location, arrived at by a comparison of the fragmentary accounts of Slavonic migrations and their distribution in historic time, agrees with the place taken by the Slavonic language among the other Indo-European languages (*see* below), and by what we know of the place-names of eastern Europe, seeing that within this area the place-names seem to be exclusively Slavonic, while outside it the oldest names belong to other languages.

In spite of the vast area which the Slavs have occupied in

historic times there is no reason to claim for them before the migrations a wider homeland than that above defined beyond the Carpathians; given favourable circumstances a nation multiplies so fast that a comparatively small race could cover a wide area in the course of four centuries. Therefore we need not seek for the Slavs among any of the populous nations of the ancient world. Various investigators have seen Slavs in Scythians, Sarmatians, Thracians, Illyrians, and in fact in almost all the barbarous tribes which have been mentioned in the east of Europe, but we can be sure that none of these were Slavs.

The Slavs made no considerable migration from their first home until the 1st century A.D. Their first Transcarpathian seat lay remote from the knowledge of the Mediterranean peoples. Herodotus (iv. 17, 51, 105) seems to mention the Slavs under the name of Neuri, on the upper waters of the Dnĕstr. They are in the right place for Slavs, and their lycanthropy suggests modern Slavonic superstitions; so we may equate Neuri and Slavs, though we have no direct statement of their identity. Other classical writers down to and including Strabo tell us nothing of eastern Europe beyond the immediate neighbourhood of the Euxine.

EARLY WRITERS

Pliny (*N.H.* iv. 97) is the first to give the Slavs a name which can leave us in no doubt. He speaks of the ***Venedi*** (*cf.* Tacitus, *Germania,* 46, *Veneti*); Ptolemy (*Geog.* iii. 5. 7, 8) calls them *Venedae* and puts them along the Vistula and by the Venedic gulf, by which he seems to mean the Gulf of Danzig: he also speaks of the Venedic mountains to the south of the sources of the Vistula, that is, probably the northern Carpathians. The name Venedae is clearly Wend, the name that the Germans have always applied to the Slavs. Its meaning is unknown. It has been the cause of much confusion because of the Armorican Veneti, the Paphlagonian Enetae, and above all the Enetae-Venetae at the head of the Adriatic. Though nowadays we have Slovenes just north of Venice, inscriptions in the Venetian language prove that it was not Slavonic. Other names in Ptolemy which almost certainly denote Slavonic tribes are the Veltae on the Baltic, ancestors of the Wiltzi, a division of the Polabs (*q.v.*), the Sulani and the Saboci, whose name is a Slavonic translation of the Transmontani of another source.

The sudden appearance in the 6th-century writers of definite names for the Slavs and their divisions means that by then the race had made itself familiar to the Graeco-Roman world, that it had spread well beyond its original narrow limits, and had some time before come into contact with civilization. This may have been going on since the 1st century A.D., and evidence of it has been seen in the southward movement of the Costoboci into northern Dacia (Ptolemy) and of the Carpi to the Danube (A.D. 200), but their Slavonic character is not established. A few ancient names on the Danube, notably that of the river Tsierna (*Černa,* black), have a Slavonic look, but a coincidence is quite possible. The gradual spread of the Slavs was masked by the wholesale migrations of the Goths, who for two centuries lorded it over the Slavs, at first on the Vistula and then in south Russia. We hear more of their movements because they were more immediately threatening for the Empire. In dealing with Ptolemy's location of the Goths and Slavs we must regard the former as superimposed upon the latter and occupying the same territories. This domination of the Goths was of enormous importance in the development of the Slavs. It explains the presence of a large number of Germanic loan words common to all the Slavonic languages, many of them words of cultural significance. "King, penny, house, loaf, earring" all appear in Slavonic, from the Goths, although the things must have been familiar before. On the other hand "plough" is said to be Slavonic, but that is not certain. When the Huns succeeded the Goths as masters of central Europe, they probably made the Slavs supply them with contingents. Indeed their easy victory may have been due to the dissatisfaction of the Slavs. Priscus (Müller, *F.H.G.* iv. p. 69, *cf.* Jord. *Get.* xlix. 258) in his account of Attila's camp mentions words which are probably Slavonic, though they have also been explained from German. After the fall of the Hunnish power the Eastern Goths and Gepidae pressed southwards and westwards to the conquest of the Empire, and the Lombards and Heruli followed in their tracks. When next we get a view of northern Germany we find it full of Slavs, *e.g.,* from Procopius (*B.G.* ii. 15), they held the Mark of Brandenburg by 512; a settlement effected without attracting the attention of any contemporary writer. The expansion of the Eastern Germans in the last centuries B.C. was made at the expense of the Slavs, who, while no more peaceful than the Germans, were less capable than they of combining for successful war, so that Goths and others were dwelling among them and lording it over them. The mutual competitions of the Germans drove some of these against the Empire, and when this had become weakened, so that it invited attack, some tribes and parts of tribes moved forward without any pressure from behind; this took away the strength of the German element, and the Slavs, not improbably under German organization, regained the upper hand in their own lands and even spread westwards at the expense of the German remnant.

Almost as uncertain is the exact time when the Southern Slavs began to move towards the Balkans. If already at the time of Trajan's conquests there were Slavs in Dacia, it would account for the story in Ps. Nestor that certain Volchi or Vlachi, *i.e.,* Romance speakers, had conquered the Slavs upon the Danube and driven them to the Vistula, for the place that the name of Trajan has in Slavonic tradition, and for the presence of an agricultural population, the Sarmatae Limigantes subject to the nomad Sarmatae on the Theiss. In any case, we cannot say that the Slavs occupied any large parts of the Balkan Peninsula before the beginning of the 6th century, when they appear in Byzantine history as a new terror; there seems to have been an invasion in the time of Justin, and another followed in 527 (Procopius, *B.G.* iii. 40 and *Hist. Arc.* 18). At the same time as the Slavs, the Huns, the Bulgars, and after 558 the Avars, were also making invasions from the same direction. The first and last disappeared like all nomads, but the Bulgars, making themselves lords of one section of the Slavs, gave it their own name. By 584 the Slavs had overrun all Greece, and were the worst western neighbours of the Eastern Empire. Hence the directions how to deal with Slavs in the *Strategicum* of the emperor Maurice (*c.* 600) and the *Tactics* of Leo.

By the end of the following century they were permanently settled throughout the whole of the Balkan Peninsula. These Southern Slavs, though divided into nationalities, are closely akin to one another. There is no reason to think the Serbo-Croats an intrusive wedge, although Constantine Porphyrogenitus (*De adm. Imp.* 30–33) speaks of their coming from the north in the time of Heraclius—the middle of the 7th century. Their dialects shade into one another, and there is no trace of any influence of the North-Western group. Constantine was probably led astray by the occurrence of the same tribal names in different parts of the Slavonic world. Meanwhile the Southern Slavs were cut off from the rest of the race by the foundation in the 6th century of the Avar kingdom in Pannonia, and after its destruction in the 7th, by the spread of the Germans south-eastwards, and finally by the incursion of another Asiatic horde, that of the Magyars, who have maintained themselves in the midst of Slavs for a thousand years. Their conquests were made chiefly at the expense of the Slovenes and the Slovaks, and from their languages they have borrowed many words in forms which have now disappeared.

Of the history of the Eastern Slavs, who were to become the Russian people, we know little before the coming of the Swedish Rus, who gave them their name and organization; we have but the mention of Antae acting in concert with the other Slavs and the Avars in attacking the Empire on the lower Danube, and scattered accounts of Muslim travellers, which show that they had reached the Don and Volga and stretched up northward to Lake Ilmen. The more southerly tribes were tributary to the Khazars.

CULTURE AND RELIGION

The general impression is one of a people which lived in small communal groups, so impatient of authority that they scarcely combined for their own defence, and in spite of indi-

vidual bravery only formidable to others when cemented together by some alien element: hence they all at one time or another fell under an alien yoke; the last survivals of Slavonic licence being the veče of Novgorod, and the Polish diet with its unpractical regard for any minority. The Slavs were acquainted with the beginnings of the domestic arts, and were probably more given to agriculture than the early Germans, though they practised it after a fashion which did not long tie them to any particular district—for all writers agree in telling of their errant nature. They were specially given to the production of honey, from which they brewed mead. They also appear to have been notable swimmers and to have been skilled in the navigation of rivers, and even to have indulged in maritime piracy on the Aegean, the Dalmatian coast and most of all the Baltic, where the island of Rügen was a menace to the Scandinavian and German sea-power. The Oriental sources also speak of some aptitude for commerce. Their talent for music and singing was already noticeable.

Of their religion it is strangely difficult to gain any real information. The word Bogŭ, "god," is reckoned a loan word from the Iranian Baga. The chief deity was the Thunderer Perún (*cf.* Lith. Perkúnas), with whom is identified Svarog, the god of heaven; other chief gods were called sons of Svarog, Dažbog the sun, Chors and Veles, the god of cattle. The place of this latter was taken by St. Blasius. A hostile deity was Stribog, god of storms. There seem to have been no priests, temples or images among the early Slavs. In Russia Vladimir set up idols and pulled them down upon his conversion to Christianity; only the Polabs had a highly developed cult with a temple and statues and a definite priesthood, perhaps in imitation of Norse or even Christian institutions. Their chief deity was called Triglav, or the three-headed; he was the same as Svętovit, apparently a sky god in whose name the monks naturally recognized Saint Vitus. The goddesses are colourless personifications, such as Vesna, spring, and Morana, the goddess of death and winter. The Slavs also believed, and many still believe, in Vily and Rusalki, nymphs of streams and woodlands; also in the Bába-Jagá, a kind of man-eating witch, and in Běsy, evil spirits, as well as in vampires and werewolves. They had a full belief in the immortality of the soul, but no very clear ideas as to its fate. It was mostly supposed to go a long journey to a paradise (raj) at the end of the world and had to be equipped for this. Also the soul of the ancestor seems to have developed into the house or hearth god (Domovój, Křet) who guarded the family. The usual survivals of pagan festivals at the solstices and equinoxes have continued under the form of church festivals.

Christianity Among the Slavs.—The means by which the various Slavonic nations were converted to Christianity has probably had more influence upon their subsequent history than racial distinctions or geographical conditions.

Wherever heathen Slavonic tribes met Christendom missionary effort naturally came into being. This was so along the Dalmatian coast, where the cities retained their Romance population and their Christian faith, from the 7th century the Croats were nominally Christian, and subject to the archbishops of Salona at Spalato and their suffragans. From the beginning of the 9th century from Merseburg, Salzburg and Passau the Gospel spread among the Slavonic tribes on the south-eastern marches of the Frankish empire, in Bohemia, Moravia, Pannonia and Carinthia. Despite the zeal of these missionaries, as Germans they belonged to a nation which was once more encroaching upon the Slavs, and as Latins (though the Great Schism had not yet taken place) they were not favourable to the use of their converts' native language. Still they were probably the first to reduce the Slavonic tongues to writing, naturally using Latin letters and lacking the skill to adapt them satisfactorily. Traces of such attempts are rare; the best are the Freisingen fragments of Old Slovene now at Munich.

In the eastern half of the Balkan Peninsula the Slavs had already begun to turn to Christianity before their conquest by the Bulgars. These latter were hostile until Boris, under the influence of his sister and of one Methodius (certainly not the famous one), adopted the new faith and put to the sword those that resisted conversion (A.D. 865). Though his Christianity came from Byzantium, Boris seems to have feared the influence of the Greek clergy and applied to the Pope for teachers, submitting to him a whole series of questions. The Pope sent clergy, but would not grant the Bulgarians as much independence as they asked, and Boris seems to have repented of his application to him. He raised the question at the Council of Constantinople (A.D. 870), which decided that Bulgaria was subject to the Eastern Church.

Cyril and Methodius.—In the same way Rostislav, prince of Greater Moravia, fearing the influence of Latin missionaries, applied to Byzantium for teachers who should preach in the vulgar tongue (A.D. 861). The emperor chose two brothers, sons of a Thessalonian citizen, Methodius and Constantine (generally known as Cyril by the name he adopted upon becoming a monk). The former was an organizer, the latter a scholar, a philosopher and a linguist. His gifts had been already exercised in a mission to the Crimea; he had brought thence the relics of S. Clement, which he finally laid in their resting-place in Rome. But the main reason for the choice was that the Thessalonians, surrounded as they were by Slavonic tribes, were well known to speak Slavonic perfectly. On their arrival in Moravia the brothers began to teach letters and the Gospel, and also to translate the necessary liturgical books and instruct the young in them. But soon (in 864) Rostislav was attacked by Louis the German and reduced to complete obedience, so that there could be no question of setting up a hierarchy in opposition to the dominant Franks, and the attempts to establish the Slavonic liturgy were strongly opposed. Hearing of the brothers' work Pope Nicholas I. sent for them to come to Rome. On their way they visited with Kocel, a Slavonic prince of Pannonia, about Lake Balaton, and he much favoured the Slavonic books. In Venice the brothers had disputes as to the use of Slavonic service-books; perhaps at this time these found their way to Croatia and Dalmatia.

On their arrival in Rome Nicholas was dead, but Adrian II. was favourable to them and their translations, and had the pupils they brought with them ordained. In Rome Constantine fell ill, took monastic vows and the name of Cyril, and died on the 14th of February 869. Methodius was consecrated archbishop of Pannonia and Moravia, about 870, but Kocel could not help him much, and the German bishops had him tried and thrown into prison; also in that very year Rostislav was dethroned by Svętopluk, who, though he threw off the Frankish yoke, was not steadfast in supporting the Slavonic liturgy. In 873 Pope John VIII. commanded the liberation of Methodius and allowed Slavonic services, and for the next few years the work of Methodius went well. In 879 he was again called to Rome, and in 880 the pope distinctly pronounced in his favour and restored him to his archbishopric, but made a German, Wiching, his suffragan. Methodius was succeeded by Wiching, who had a new pope, Stephen V. (VI.) on his side. So the Slavonic service-books and those that used them were driven out by Svętopluk and took refuge in Bulgaria, where the ground had been made ready for them. Boris, having decided to abide by the Greek Church, welcomed Clement, Gorazd and other disciples of Methodius. Clement, who was the most active in literary work, laboured in Ochrida and others in various parts of the kingdom.

In spite of the triumph of the Latino-German party, the Slavonic liturgy was not quite stamped out in the west; it seems to have survived in out-of-the-way corners of Great Moravia until that principality was destroyed by the Magyars. Also during the life of Methodius it appears to have penetrated into Bohemia, Poland and Croatia, but all these countries finally accepted the Latin Church, and so were permanently cut off from the Orthodox Serbians, Bulgarians and Russians. (X.; N. B. J.)

SLEAFORD, a market town in Lincolnshire, England, in a fertile and partly fenny district on the river Slea. Pop. of urban district (1931) 7,024. The fine church of St. Denis exhibits transitional Norman work in the base of the western tower. The nave is of beautiful late Decorated work with an ornate south porch. There is a splendid carved rood screen of oak. The chancel is Perpendicular. There are a few picturesque old houses. Malting and agriculture furnish the industries.

The discovery of numerous coins of the Constantine period,

the earthworks of the castle-area, and its proximity to the ford by which Ermine Street crossed the Witham, point to the probability of Sleaford (*Slaforde, Lafford*) being on the site of a Roman settlement or camp, and that the Saxons occupied the site before their conversion to Christianity is evident from the large cemetery discovered here. Domesday Book records that the manor had been held from the time of Edward the Confessor by the bishops of Lindsey, whose successors, the bishops of Lincoln, retained it until it was surrendered to the Crown in 1546. The quadrilateral castle, with its square towers and massive keep, was built by Alexander, bishop of Lincoln, and became one of the chief episcopal strongholds. Sleaford never became a borough, and the government was manorial, the bishops exercising jurisdiction. The townsfolk were organized in the guilds of Corpus Christi, St. John and Holy Trinity, accounts of which, date from 1477.

See *Victoria County History, Lincolnshire;* G. W. Thomas, "On Excavations in an Anglo-Saxon Cemetery at Sleaford, Lincolnshire," *Archaeologia*, vol. i. (London, 1887); Edward Trollope, *Sleaford and the Wapentakes of Flaxwell and Aswardhurn in the county of Lincoln* (London, 1872).

SLEEMAN, SIR WILLIAM HENRY (1788–1856), Indian soldier and administrator, born at Stratton, Cornwall, on Aug. 8, 1788, joined the Bengal army in 1809, and served in the Nepal War (1814–1816). He suppressed the Thugs or religious murderers in India, becoming superintendent of the operations against them in 1835, and commissioner for the suppression of Thuggi and Dacoity in 1839. During these operations more than 1,400 Thugs were hanged or transported for life, one of whom confessed to having committed over 700 murders. Detection was only possible by means of informers, for whose protection from the vengeance of their associates a special gaol was established at Jubbulpore. Sleeman was resident at Gwalior 1843–1849, and at Lucknow 1849–1856. He died at sea on his way home on Feb. 10, 1856.

See Sir H. Sleeman, *Rambles and Recollections of an Indian Official* (1844; 2nd edition, 1893), and *A Journey through Oudh* (1858).

SLEEP. Sleep is a normal condition of the body which occurs periodically. During sleep there is greater or less depression of most physiological activities, accompanied by a greater or less degree of unconsciousness. Until the present century, neither physiologists nor psychologists have been able to offer any explanation of the cause or nature of normal sleep.

Sleep as we know it in man is observed only in those animals which stand on a comparatively high level of development as regards their central nervous system. It is however possible that the periods of rest in the daily cycle of some invertebrates are of a nature akin to that of sleep. Amongst the vertebrates, even fishes show unmistakably a periodical sleep, and in birds this assumes all the characteristics of the typical sleep of a mammal.

Bodily Manifestations of Sleep.—The most striking manifestation of sleep is the partial or complete depression of the higher nervous activities, a state which is subjectively described as unconsciousness. However it is not only the higher parts of the central nervous system that are involved. Those parts which regulate posture and the tonic state of the skeletal muscles, and even those which regulate the respiratory movements and tone of the blood vessels are also found to be depressed during sleep.

As the result of an almost complete relaxation of the muscles, all signs of muscular activity diminish. The general metabolism is depressed and reaches the lowest level of the day. If we take the average daily metabolism of an adult as about 3,000 calories, only about 600 of these will be used during 8 hours of sleep, about 750 during 8 hours of the wakeful state at rest, and about 1,650 during 8 hours of mild muscular activity. As regards the state of metabolism we may, therefore, regard sleep as equivalent to almost complete rest of the skeletal muscles. Since the process of reconstruction of organs, *i.e.,* their recovery after a preceding period of activity, can take place only in the absence of these activities, it is natural that sleep should afford a better opportunity for recovery from fatigue than simple rest, in which the muscles are never in as complete relaxation as during sleep. Whether the metabolism of other organs is also diminished during sleep has not yet been ascertained. It is known, however, that all digestive processes, such as the secretion of the digestive juices, the movements of the gastro-intestinal tract and the absorption of food substances, proceed in a normal manner; but these functions are not so intimately dependent on the central nervous system as are those of the skeletal muscles.

Under normal conditions in the state of wakefulness, the regulatory functions of the nervous system are so delicately adjusted that they tend, by various mechanisms, to counteract any violent changes in the internal conditions of the body which would otherwise be caused by changes in the environment. A large number of the mechanisms involved in this "self preservation" of the organism are dependent on the proper functioning of the central nervous system, and in sleep, on account of the depression of this system, the compensatory activities of the organism are not at such a high pitch of efficiency as in wakefulness.

Temperature.—The temperature regulation is less efficient: the diminished production of heat is not completely compensated by a diminution of heat loss, and the temperature of the organism falls. Thus, exposure to cold may lead to a considerably greater change of body temperature in sleep than otherwise. This relatively greater cooling of the organism may probably start some time before actual sleep has commenced. This may be the cause of the subjective feelings of cold if sleep is delayed. It is well known that the temperature of man exhibits daily fluctuations; it is usually highest about 5 to 7 P.M. and falls during the night, reaching the lowest point early in the morning. These variations in temperature may amount to a degree or more Centigrade. They have been shown to be independent of the cosmic phenomena of day and night, and directly related to sleep and wakefulness. The most conclusive proof of this is that the temperature of people who work during the night and sleep during the day also falls during the periods of sleep, the highest temperature occurring at night which is, in these cases the period of greatest activity. The regulation of temperature is to a large extent due to muscular activity, and since this is depressed during sleep, the regulation of temperature is not at all adequate during periods of sleep. This compels us to seek warmer covering during sleep, while animals try to diminish their exposed surfaces by curling up, etc. Conversely, the animal is to a large extent hindered from falling asleep by any conditions which provoke an increase in metabolism, exposure to cold being one of them.

Respiration.—The respiration during sleep becomes slower and deeper. It is reported that it becomes predominantly costal, the diaphragmatic contractions becoming considerably weaker than they are normally. Often the respiratory movements become periodical in character, tending to rise and fall in strength. The depression of respiration is such that, although the production of carbon dioxide in sleep is considerably smaller, the concentration of carbon dioxide in the alveolar air is unmistakably increased. A similar increase during the wakeful state would cause an immediate augmentation of the respiratory activity. The nitrogen elimination remains unchanged, which means that the protein metabolism is not affected.

Heart Action.—The heart rate during sleep is slower, but it is not known whether this is due to an increased tone of the cardioinhibitory nerves, or to a diminished tone of the accelerator nerves. The vasomotor centre is also depressed, as the result of which the peripheral blood vessels dilate and the arterial blood pressure declines. The cutaneous blood vessels largely participate in this vasodilation so that in some cases pulsation of the veins can be observed during sleep. The blood pressure in very deep sleep exhibits little fluctuation, except for the usual respiratory variations, but in sleep which is not profound changes in the blood pressure have been observed which may exceed those which occur during ordinary resting conditions. The nature of these fluctuations is not clear. They may occur spontaneously and may possibly be dependent on the nervous activities associated with dreams. Interesting experiments were carried out on the volume occupied by a man's arm during sleep. It was found that the arm increased in volume on account of vasodilation. After the maximum dilation is reached, the arm remains more or less of the

same volume for a certain period, or else the volume diminishes very gradually. Shortly before the awakening, the arm begins to diminish more rapidly in size, doubtless owing to the contraction of its blood vessels. At the time of waking, it has practically the same volume as it had at the beginning of sleep. On account of dilation of the peripheral blood vessels during sleep, there is a considerable redistribution of blood; less blood is now available for the brain, and possibly less for some other internal organs.

Brain Circulation.—The state of the circulation of the brain has frequently been investigated. It has been observed that during sleep the surface of the exposed brain becomes pale (Johann Blumenbach 1752–1840). A careful research was conducted by A. E. Durham in 1860, in which he trephined a portion of bone in the parietal region of a dog and inserted a watch-glass in the opening to prevent the effects of atmospheric pressure. He found that during sleep the brain is relatively more anaemic. Other experiments confirmed these observations, and Mosso (1881) extended the experiments to man. He made observations on three persons who had lost a portion of the cranial vault, and in whom there was a soft pulsating cicatrix. The subjects were a woman of thirty seven years of age, a man of thirty seven years of age, and a child of about twelve years. By special arrangements, Mosso took simultaneous tracings of the pulse at the wrist, of the beat of the heart, of the movements of the wall of the chest in respiration, and of the movements of the denuded brain. Further, he obtained tracings showing changes in the volume of the hand and forearm; and he succeeded in showing that during sleep there is a diminished amount of blood in the brain, and at the same time an increased amount in the extremities. The blood flow through the retina is also diminished during sleep. The apparent explanation of the cerebral anaemia during sleep is that the blood vessels of the body dilate, and therefore receive more blood, while a smaller amount flows to the brain; it is not due to an active constriction of the cerebral blood vessels. Whilst muscular relaxation is general, there seems to be an increased contraction of certain sphincter muscles, such as the circular fibres of the iris and the fibres concerned in closing the eyelids; the pupils of the eyes are contracted and the eyeballs are rotated upwards.

Effect of Sensory Stimuli.—All kinds of stimuli may affect the sleeping individual and produce certain physiological effects without awakening him; they may cause movements, changes in respiration, dilation of the pupil, considerable changes in the cardiovascular system, and also they may provoke dreams. Measurements of the volume of a limb show that, during the application of various stimuli, the limb diminishes in volume more or less in proportion to the intensity of the stimulus. The probable explanation of this is that the sensory stimuli act reflexly upon the vasomotor centre in the medulla, and in this way cause contraction of the blood vessels. Thus Mosso found that a strong stimulus to the skin or to a sense organ—but not strong enough to awaken the sleeper—caused a contraction of the vessels of the forearm, an increase of blood pressure, and an increased flow of blood towards the brain. So sensitive is the whole organism in this respect, even during sleep, that a loudly spoken word, a sound, a touch, the action of light or any moderate sensory impression modified the rhythm of respiration, determined a contraction of the vessels of the forearm, increased the general pressure of the blood, caused an increased flow to the brain, and quickened the frequency of the beats of the heart. These observations show how a physiological explanation can be suggested of the influence of external impressions in modifying the dreams of a sleeper. Further, Mosso found that during very profound sleep these oscillations disappear: the pulsatory movements are uniform and are not affected by sensory impressions, and probably this condition exists when there is the unconsciousness of a "dead" sleep.

The Intensity of Sleep.—The intensity of sleep has been measured by the intensity of sound necessary to awaken the sleeper. Kohlschütter used for this purpose a pendulum falling against a metal plate. At intervals of half an hour during the period of sleep, the auditory stimuli produced in this way were increased in intensity until waking was caused. According to these observations, the greatest intensity is reached about an hour after the beginning of sleep. From the second or third hour onwards, the depth of sleep is very slight, the activities of the brain being just below the threshold of alertness. The period from the third hour to the moment of spontaneous awakening is, presumably, as important for the restoration of the brain to its normal waking condition as the deeper period of the first two–three hours. The recuperative power of sleep, therefore, does not appear to be proportional to its intensity. The change in the intensity of sleep varies greatly in different individuals. In many, especially in children, there is a second period of slightly increased intensity of sleep between the fourth and fifth hour. In children of four years with a normal period of sleep of about twelve hours, there is a marked increase in intensity about an hour before the awakening.

Theories of Sleep.—Confining ourselves to the more recent attempts to explain the cause of sleep, we have the following:

1. *The Accumulation of the Acid Products of Metabolism.*—It has been suggested that this accumulation took place during the period of activity and led to a diminution of the irritability of the central nervous system.

2. *Consumption of the Intramolecular Oxygen.*—According to this theory, the cells are able to store oxygen (intramolecular oxygen), which is used during activity more rapidly than it is formed, thus causing a state of partial anoxaemia. During sleep the intramolecular oxygen, that is the oxygen which is combined with the protoplasm to form the irritable living matter, is again replenished.

3. *Toxin Theory.*—It has been supposed that a special toxin, which might be called hypnotoxin, is formed during the waking hours and finally accumulates to such an extent that it diminishes the irritability of the central nervous system.

4. *Neuron Theory.*—This theory explains sleep as due to a temporary retraction of the dendrite processes of nerve cells which leads to a disruption of the continuity of the nerve paths in the central nervous system. All these theories have now been practically abandoned for lack of direct experimental evidence.

5. *Inhibitory Theory.*—During recent years a vast amount of experimental material relating to the genesis and intimate nature of sleep has been brought forward by Pavlov. Together with his co-workers, Pavlov has studied in animals reflexes which involve the co-operation of the higher nervous centres, *i.e.*, of the cortex of the hemispheres. For a description of this important branch of physiology, the reader is referred to the section on Brain and to original treatises.

Conditioned reflexes are based on the associative function of the brain. To give a simple example: if the feeding of an animal is repeatedly accompanied by some stimulus, *e.g.*, a note or other sound, some visual, olfactory, tactile or in fact any stimulus whatever, it is observed that when the stimulus is applied alone it evokes the same effect as feeding, namely the appropriate muscular and secretory responses. The magnitude of these responses depends on many conditions, one of which is the intensity of the accompanying stimulus. A strong sound, after it has been associated with feeding, when applied alone evokes a stronger secretory and motor response than does a subdued sound under the same conditions. Conditioned reflexes have been successfully employed for the purpose of determining the scope of various perceptions of animals, for instance the upper and lower limits of audition, colour vision, etc., and also for the determination of the precision in discrimination between closely resembling stimuli. If, for instance, one note is always accompanied by feeding while another is not, it will be found that only the first note will evoke the reflex. The second will have no visible effect.

Further studies however have shown that these apparently ineffective stimuli actually produce a considerable inhibition of that part of the brain on which they act. This state of inhibition lasts for some time and is of a measurable intensity. The transition of the cortex into an inhibitory state is very rapid in the case of conditioned stimuli which are not associated with some definite activity of the animal, and the inhibition is very profound. This inhibition remains as an after-effect and readily undergoes summation with the effect of any other inhibitory stimuli which may chance to affect the brain. The inhibition in these cases not only

becomes more intense but it also begins to involve other areas of the brain, areas which were not affected in the first instance but which now lose their excitability on account of this spreading inhibitory influence; on stimulation of these areas with appropriate conditioned stimuli, they give either no reflex effect or a greatly diminished one. A great number of conditions are known in which various conditioned stimuli acquire inhibitory properties and which on administration set up a state of diminished excitability and inhibition in the brain. On repetition of these inhibitory stimuli, a stage is reached when no conditioned reflex response can be obtained.

Such a state of widely spread inhibition is easily produced and is the common and everyday occurrence of sleep. The fundamental condition for the appearance and development of inhibition which is localised in some definite part of the brain is exactly the same as that of sleep. From the point of view of conditioned reflexes, the brain is never active as a whole. Areas of inhibition are intermixed with areas of excitation, and these always antagonise the tendency of the inhibition to spread over the whole brain. Even when the inhibition has attained a mastery over the brain, there may always remain areas which will be in an excitatory state, which is however not strong enough to keep the animal in a state of alertness.

Thus sleep is nothing but a state of inhibition which is always present in some areas of the brain, but which has now become diffused continuously (with practically no intervening fields of excitation) over the entire cortex and which has descended also to some of the lower parts of the brain. The development of inhibition is very rapid in the case of conditioned stimuli which do not lead to some activity; it must however be considered as only a special instance of a more general case, since a state of inhibition can also develop when the stimuli are associated with and followed by the respective activity.

Inhibitory Theory Considered.—The details of the experimental results obtained and of our normal everyday existence are in full agreement with the foregoing interpretation of sleep. Our daily work, for some a round of exceeding monotony and for others extremely rich and varied, in either case must in the end determine an appearance of sleep. A prolonged stimulation of one and the same point in the cortex by a conditioned stimulus ultimately leads to a great and profound inhibition, and this irradiates so as to involve the whole cortex and the lower parts of the brain. In the case of a varied activity, although no given point of the cortex attains such a profound depth of inhibition, yet the great number of inhibitory points leads to a widely distributed inhibitory state even without an intensive irradiation, and this also descends to affect some of the lower centres of the brain. A great number of quickly changing stimuli following in succession and leading to some activity of the animal may often exert a very prolonged and powerful resistance to the general dissemination of inhibition, thus delaying the onset of sleep. A well-established rhythm in the changes from wakefulness to sleep may facilitate this wide-spreading of the inhibition leading to sleep.

Since, as we know, the spread of inhibition is a gradual process, involving first a smaller and then a greater area, we should expect to find various transition stages between the fully alert state and complete sleep. Such transition stages actually exist, and they have been studied in considerable detail by observing the conditioned reflexes of the animal. Sleep in animals often exhibits the following peculiar form. As in fully developed sleep, the activity of the hemispheres is absent, all conditioned stimuli remain without effect, and different extraneous stimuli, unless exceptionally powerful, fail to evoke any reaction. Nevertheless the animal preserves an entirely alert posture; it stands with wide-open eyes, head up, extremities extended, not seeking support; sometimes it remains motionless for minutes and sometimes for hours. On changing the position of an extremity, the extremity retains the new position. Presentation of food gives no reaction, and the animal continues to remain still. As the result of careful observations of man and animals, it may be said that this transition state from the alert state to sleep is always present before the development of complete sleep, though only in a fleeting form.

A similar demarcation of excitable areas which have undergone complete inhibition may exist also between different large areas of the cortex itself, producing what may be called localised sleep. This form is frequently seen and can be produced experimentally. For instance, secretory activities may be present and of normal magnitude, while all motor activities are already inhibited. The inhibition in such a case must have spread over the motor area of the cortex so that the excitation induced by the conditioned stimulus could reach the glands but not the muscles. The above observations demonstrate that the extent of the spread of the diffused inhibition in the brain may be small or great, and that there may exist different transition stages in the depth of the inhibition or, in other words, different intensities of the diffused inhibition, sleep. Bearing in mind the fact that in alertness the strength of the conditioned reflex is determined, *ceteris paribus*, by the strength of the stimulus, we can proceed to study with some degrees of definiteness the different stages through which the diffused inhibition develops.

On measuring the strength of conditioned reflexes during the period of spontaneously developing or experimentally induced sleep, it is found that, before conditioned reflexes disappear altogether, they pass through a variety of stages in which the normal relation between the strength of response and the strength of stimulus is altered in some way. There is, for instance, a phase in which the animal responds to all conditioned stimuli, whether strong or weak, but the usually weak responses become somewhat stronger, and the strong ones become somewhat weaker. Reflexes which showed differences of about 100% in strength are now equalised. This phase is known as the phase of equalisation. With further development of sleep, it is found that the weak stimuli produce a definitely greater response (in some cases 100% greater) than the strong stimuli. This phase is known as the paradoxical phase. Finally, with a still further intensification of sleep, all conditioned reflexes vanish completely, and this is followed sooner or later by the relaxation of the muscles and the development of complete sleep. The process of awakening seems to go through the same stages.

Other changes in strength of conditioned reflexes have been observed. The question whether they can be arranged in a definite order, and if so in what order, must remain entirely open for the present. All these different states of activity of the hemispheres bear a strong resemblance to the different stages of what is generally known as hypnotism, which from the point of view of conditioned reflexes is merely a transition stage between alertness and complete sleep, a stage of a greater or less extent and a greater or less intensity of sleep. Inhibition or localised sleep is a phenomenon always present, under whatever conditions the animal or man may be. The state of alertness is only an expression of a predominance of excitation, while sleep is due to a predominance of inhibition. (G. An.)

SLEEPER. A term used with many technical applications for a piece of timber, metal, etc., used as a support; in carpentry it is such a piece of timber laid on low cross walls as a plate to receive ground joists; in shipbuilding, a strengthening timber for the bows and stern frame. The most frequent use of the term is for a timber or steel support on which the chairs are fixed for carrying the rails on a railway; in America these are more commonly called "ties" (*see* Railways). It is an error to derive the word from "sleep." Its real source is the Norwegian *sleip*, meaning a roller or timber laid along a road. This word Skeat (*Etymol. Dict.*, 1898) connects with "slab." The French term *dormant* which is equivalent to "sleeper," is used for a part of the frame of a window or door which cannot be opened.

Sleeper is also used as an abbreviation for sleeping car.

SLEEPING-SICKNESS (*Trypanosomiasis*), a parasitic disease, familiar among West African natives since the beginning of the 19th century, and characterized by protracted lethargy, fever and wasting. It is caused by the *Trypanosoma gambiense,* a parasite which was discovered in the frog by Gruby in 1847, and in 1880 by Griffith Evans in horses afflicted with the disease called "surra" in India. In 1895 Surgeon-Major (afterwards Sir) D. Bruce found a trypanosoma similar to Evans's in cases of what was known in cattle as "tsetse-fly disease"; and though the trypanosoma had not then actually been found in man, Bruce suggested that this was akin to the human "sleeping-sickness" which had now extended into the Congo Free State, Uganda and elsewhere, and was causing great mortality, many Europeans having died of the disease. In 1903 Castellani found the trypanosoma in the cerebro-spinal fluid of human patients afflicted with the disease. The pathology of "sleeping-sickness" was vigorously taken up, and in June 1907 an international conference was held in London to organise research.

The problems were: (1) to determine whether the tsetse fly (*glossina palpalis*) was a direct or indirect conveyor of the parasite; (2) whether the parasite underwent necessary developmental changes in the tsetse fly; (3) if so, whether the developed germs were conveyed by the original fly or its larva when arrived at the imago stage; (4) how long an infected *glossina palpalis* remained infected; (5) whether other species of *glossina* were concerned; (6) the geographical distribution and habits of the fly; (7) whether and how far the spread of infection was the work of any of the vertebrate fauna (other than man); (8) to suggest preventive methods for exterminating the *glossina,* or protecting uninfected districts by segregation or otherwise; (9) to study the therapeutics of the disease.

Transmission of Infection.—It was at first believed that the transmission of *Trypanosoma gambiense* by the tsetse fly, *Glossina palpalis,* was direct or mechanical, and that a fly lost its power of infecting 24–48 hours after feeding on an infected man. Kleine (1909) showed that this is not the case. In a certain percentage of flies the germs ingested with the blood do not die but multiply exceedingly in the fly's gut, change in form, come forward and at last invade the salivary glands, where they resume their blood form. Modern treatment is by injection of organic arsenical compounds (atoxyl and arsacetin) or of tartar emetic, a salt of antimony.

During the process, which occupies 14–28 days or more, the fly is not infective, but when the germs are established in the salivary glands it regains its infectivity and may retain it for a long period, for at each feed germs are poured into the puncture. Unless the salivary glands contain the germs a fly is not capable of infecting, but only in a small proportion is this development completed; in nature the proportion of infected flies rarely exceeds one in 1,000. Conveyance is therefore indirect. Direct infection may occur in nature, but the failure of the disease to spread in the absence of tsetse, even though biting insects of many kinds are present, seems to show it must be rare, *e.g.,* hundreds of cases of sleeping-sickness were recorded in the West Indies among slaves brought from Africa, but there is no recorded instance of spread in the New World. The disease was formerly rife in the island of Principe in the Gulf of Guinea, where *G. palpalis* abounded, but no cases occurred in the neighbouring island of San Thomé, with the same insect fauna, but, like America, with no tsetse. Duke believes that when the disease is epidemic direct infection is the rule. There is no evidence that the fly can transmit the germs to its offspring. The fly has been shown to be capable of infecting for at least 96 days.

Other species of *Glossina, e.g., G. morsitans* and *G. tachinoides,* become similarly infected. But some species rarely attack man.

Trypanosoma Rhodesiense.—In 1909 a second species of trypanosome was discovered in a case of human infection from Rhodesia and called *T. rhodesiense.* It is found in areas infested not by *G. palpalis* but by *G. morsitans,* and was shown by Kinghorn and Yorke (1911) to be conveyed by this species and to undergo in it a similar development. *T. rhodesiense* infections are found in Nyasaland, Portuguese East Africa and Tanganyika Territory, besides northern Rhodesia, and, rarely, south of the Zambezi river. *T. rhodesiense* cannot be distinguished from *T. gambiense* by its appearance in human blood; after inoculation into animals microscopical differences can be detected; since such inoculations are rarely made it may be more often the cause of sleeping-sickness than is believed: its carrier is widely distributed. Indeed, a few cases have been found as far north as the Anglo-Egyptian Sudan; and near Mwanza, south of Lake Victoria, a small epidemic occurred in 1922, conveyed by a tsetse akin to *G. morsitans.* This type of human trypanosomiasis is rarely epidemic; cases occur in sporadic fashion. It is more acute and more rapidly fatal than the *T. gambiense* variety, and is more resistant to drugs. Whether or not *T. rhodesiense* is identical with *T. brucei* the parasite of *nagana,* first described by Bruce in Zululand (1893), is undecided. Bruce and Yorke consider them to be the same; Kleine makes a distinction. They cannot be separated by their appearance under the microscope, the symptoms and course of the illness produced in animals, or the manner and site of development in the tsetse. Both complete their development in the salivary glands.

T. brucei and *T. rhodesiense* are found in big game, especially waterbuck, bushbuck, reedbuck, haartebeest, on which *G. morsitans* feeds. These animals are, therefore, reservoirs of germs capable of infecting man, and much discussion has taken place as to the rôle played by big game in the spread of *T. rhodesiense,* some claiming that the passage of the parasite is game, fly, man; others that it is man, fly, man. The point is still undecided.

An experiment was made in East Africa during the World War in which blood was taken from transport animals infected with *T. brucei* and inoculated by Taute into himself, his colleague Huber and 127 natives. Though animals inoculated at the same time always became infected there was no single instance of infection in man. They concluded that man is immune to infection by *T. brucei.* This striking experiment, however, does not convince those who believe man to be susceptible but very resistant of *T. gambiense,* it is generally agreed that infected man is the chief reservoir of infection, though Bruce (1911) found that antelopes can be infected with this trypanosome by allowing infected *palpalis* to feed upon them, and they continue to harbour the trypanosomes in their blood for many months.

Treatment.—Sleeping-sickness is now treated by compounds of arsenic, especially *atoxyl* and *tryparsamide,* the latter a product of the Rockefeller Institute; by compounds of antimony, as tartar emetic; and by a drug of undisclosed composition called Bayer 205, or Germanin. The French and Belgians use *atoxyl* largely in the African villages, where doses are injected at the proper intervals by trained natives. A high degree of success is claimed, both curative and preventive, in that the blood is kept free from germs which might be taken up by the tsetse. *Antimonials* are used as a rule in conjunction or alternation with arsenicals. *Bayer 205,* first employed in the treatment of man in 1921, has remarkable successes to its credit in Europeans, especially in cases of the Rhodesian type which were refractory to other drugs; unless used with caution it has a harmful effect on the kidneys. It has been less successful in natives, perhaps because infection is usually detected in them at a later stage when the spinal cord and brain are affected, and at this stage treatment nearly always fails. French chemists have prepared the same or a similar drug. *Tryparsamide,* introduced about the same time, appears to be still more potent, and especially in cases in which the nervous system is involved, but it also has a serious effect in that it sometimes affects vision. Though sleeping-sickness in the European is nearly always a fatal disease if left untreated, in the natives of parts of Africa it is very chronic, does not interfere with the patient's activities, and almost certainly may end in natural recovery.

International Conference.—At the suggestion of the League of Nations an International Conference on Sleeping Sickness met in London in 1925. In its recommendations it laid down administrative measures which should be taken on both sides of the frontiers between infected countries for the control of the disease, and advised the dispatch to Uganda of a commis-

sion to study the problem. The commission started work in 1926 and in 1927 issued an interim report. The programme is divided into Epidemeological Studies and Laboratory Work. The conclusions so far are tentative only.

SLEEPY SICKNESS: *see* ENCEPHALITIS LETHARGICA.

SLEET, a precipitation of mixed rain and snow or of partly melted snow. Snow passing through a layer of comparatively warm air may be partly melted and reach the ground in a semi-liquid condition. If the ground is below freezing point, the sleet may become solid ice (*glazed frost*).

SLEIDANUS, JOHANNES (1506–1556), German historian, the annalist of the Reformation, was born at Schleiden, near Aix-la-Chapelle. He studied ancient languages and literatures at Liége and Cologne, and law and jurisprudence at Paris and Orleans. Whilst among the humanists of Liége, he had adopted Protestant opinions, and entering the service of Cardinal du Bellay, was employed in the futile negotiations of the French court to make an alliance with the German Protestants against the emperor Charles V. In 1542 he settled at Strassburg. Sleidanus had been accustomed to copy all papers bearing upon the Reformation to which he had access, and Martin Bucer proposed to Philip of Hesse to appoint him historian of the Reformation, giving him a salary and access to all necessary documents. Sleidanus began his great work, finishing the first volume in 1545. In that year he went to England in a French embassy to Henry VIII. While there he collected materials for his history. On his return he represented Strassburg at the diets of Frankfort and Worms, and went on to Marburg to explore the archives of Philip of Hesse. The war of the league of Schmalkalden interfered with this work, and also prevented the payment of Sleidanus, who received a yearly pension from Edward VI. In 1551 Sleidanus represented Strassburg at the council of Trent, being charged to act also for the imperial cities of Esslingen, Ravensburg, Reutlingen, Biberach and Lindau. He was afterwards appointed professor of law in Strassburg, and finished his great task in 1554, though lack of money and other misfortunes compelled him to delay printing. Sleidanus died in poverty at Strassburg in October 1556. The book appeared in the preceding year—*Commentariorum de statu religionis et reipublicae, Carolo V. Caesare, libri XXVI.;* it was translated into English by John Daws in 1560 and by G. Bohum in 1689. It was so impartial that it pleased no one, not even Melanchthon. It remains the most valuable contemporary history of the times of the Reformation, and contains the largest collection of important documents.

See H. Baumgarten, *Über Sleidanus Leben und Briefwechsel* (1878), and *Sleidans Briefwechsel* (1881); and A. Hasenclever, *Sleidan-Studien* (Bonn. 1905).

SLEIGH, SLED or **SLEDGE,** a vehicle on runners instead of wheels, for travelling over snow or ice. The sleighs used in COASTING are referred to in the article under that heading; but for ordinary means of conveyance horse-drawn sleighs are employed as carriages in countries such as Russia, Scandinavia and North America. In the Arctic regions dogs are harnessed to them.

SLEZSKÁ OSTRAVA, a town in Silesia, Czechoslovakia, lies near Moravská Ostrava (*q.v.*) on the Ostrava-Karvinná coal-field, and is a colliery town. Pop. (1921), 22,890.

SLIDELL, JOHN (1793–1871), American diplomatist, was born in New York in 1793. He graduated from Columbia college in 1810, studied law, and practised at New Orleans, La., where he settled in 1825. He belonged to the House of Representatives as a state's rights Democrat from 1843 to 1845, when he resigned and was sent by President Polk on a secret mission to Mexico, with power to adjust the difficulties growing out of the annexation of Texas to the United States, and to acquire by purchase both New Mexico (including the present Arizona) and Upper California. He was not, however, received by the Mexican government. From 1853 to 1861 he represented Louisiana in the Senate. He is supposed to have assisted Buchanan's nomination for the presidency in 1856. When Louisiana seceded in 1861, Slidell withdrew from the Senate, and late in 1861 was sent by the Confederate Government as commissioner to France. With James M. Mason (*q.v.*), the Confederate commissioner to England, he was taken from the British steamer "Trent" by Captain Charles Wilkes of the United States navy, and was imprisoned at Fort Warren in Boston harbour. In Jan., 1862, at the demand of England, the Confederate commissioners were released, and Slidell proceeded to France. His mission there was to secure the recognition of the Confederate States; in this he was unsuccessful, but he was able to secure supplies for the Confederate army and navy. After the war he settled in England, and his daughter married a French nobleman. He died in London on July 29, 1871.

See Samuel Abbott Green, *James Murray Mason and John Slidell in Fort Warren, Boston Harbor* (1912); Louis Martin Sears, "A Confederate Diplomat at the Court of Napoleon III.," in *American Historical Review*, vol. xxvi. p. 255–281 (1921); and Louis Martin Sears, *John Slidell* (1925).

SLIDE RULE, a rule consisting of graduated scales capable of relative movement, by means of which simple calculations may be carried out mechanically. In ordinary slide rules these operations include multiplication, division and extraction of square roots, as well as, in some cases, calculation of trigonometrical functions and logarithms. It is an instrument much used by engineers. (*See* CALCULATING MACHINES, MATHEMATICAL INSTRUMENTS.)

SLIGO, a county of Ireland in the province of Connaught. The area is 452,356 acres or about 707 sq.m. Pop. (1926) 71,393. The coast-line is very irregular, the principal inlets being Killala Bay and Sligo Bay. Among the islands are Inishmurray and Coney. In the north are the limestone elevations of Ben Bulbin (1,712 ft.) and Knocknarea (1,078), contrasting with the adjacent rugged gneiss mountains, among which are King's Mountain (1,527) and Gullogherboy (1,430). On the boundary with Leitrim, Truskmore reaches a height of 2,113 ft. In the west are the ranges of the Slieve Gamph and Ox Mountains, upwards of 1,300 and 1,600 ft. respectively. The Curlew Mountains, an abrupt ridge of limestone gravel, upwards of 800 ft. in height, with flattened summit, separate Sligo from Roscommon. The principal rivers are the Moy, flowing into Killala Bay; the Easky, flowing northward from Lough Easky; the Ballysadare; and the Garvogue, or Garavogue. Lough Gill (extending into Leitrim), Lough Arrow and Lough Gara exceed 3,000 acres in extent. The salmon, sea-trout and trout fishing are excellent.

The county was created by Sir Henry Sydney in 1579. At Drumcliffe (5 m. N. of Sligo) are the only round tower remaining in the county and a Celtic cross 13 ft. in height. The principal monastic ruins are the abbey of St. Fechan at Ballysadare, with a church of the 11th or 12th century; the abbey of Sligo; and a group of buildings on the island Inishmurray, which include a cashel or walled enclosure; three oratories; two holy wells; and also altars, pillar stones, inscribed slabs (one of which has an inscription partly in Latin), and several examples of beehive cells. This settlement is associated with Molaise, a saint of the early 6th century (not identical with the Molaise of Devenish in Loch Erne), and the remains still attract pilgrims.

In some parts the soil is a light sandy loam resting on a free-stone bottom, and in the lower districts a rich and deep mould prevails resting on a substratum of limestone. Owing to the moistness of the climate cattle feeding is found to be the most remunerative method of farming. Oats and potatoes are the principal crops, but the acreage devoted to them decreases. Coarse woollens and linens are manufactured for home consumption, and there are tanneries, distilleries, and breweries in the principal towns. Lead was mined at Ballysadare, and the clay-ironstone from the east of the county was at one time smelted. A considerable general trade is carried on at the ports of Ballina (on the Moy) and Sligo. The fisheries on the coast are valuable, and there are important salmon fisheries at the mouths of the

rivers. The town of Sligo is the chief centre.

The Great Southern lines from Limerick and from Dublin meet at Collooney Junction which is also used by the Sligo, Leitrim and Northern Counties line. The three routes unite in the section from Collooney to Sligo town. From Kilfree on the main Dublin line a branch serves Ballaghaderreen in Co. Mayo. The counties of Leitrim and Sligo together return 7 members to Dáil Eireann.

SLIGO, a seaport and county town of Co. Sligo, Ireland. Pop. (1926) 11,439. It lies on Sligo Bay and the river Garvogue, 134½ m. N.W. from Dublin by the Great Southern railway.

The Dominican Abbey, founded in 1252, was partly destroyed by fire in 1414 and again in 1642. Three sides of the cloisters remain, and the lofty quadrangular tower at the junction of the nave and chancel is entire. The east window is of the date of the original structure. The Roman Catholic cathedral (1869) for the diocese of Elphin is in the Norman style. There is also a Roman Catholic college.

A castle, built by Maurice Fitzgerald in 1242, was in 1270 taken and destroyed by O'Donnel; in 1310 it was rebuilt but was again partly destroyed in 1369 and 1394. Of this and the walls with which the town was fortified there are no remains. Early in the reign of James I. the town received a market and two annual fairs; in 1613 it was incorporated and received the privileges of a borough; and in 1621 it received a charter of the staple. In 1641 it was besieged by the Parliamentary forces, but was afterwards evacuated, and occupied by the Royalists till the termination of the war. In 1688 it declared in favour of James II., and, after being captured by the Enniskilleners, was retaken by General Sarsfield, but ultimately surrendered to the earl of Granard. The borough was disfranchised in 1870.

Three miles S.W. of the town, on Carrowmore, is a remarkable collection of megalithic remains, including dolmens, stone circles, and burial cairns, which has been taken to mark the site of the traditional battle of North Moytura. On Knocknarea (1,078 ft.), south of Sligo, is a cairn, which tradition sets down as the burial-place of Queen Mab (Meave of Connaught).

Sligo takes rank with Galway and Limerick as one of the three principal ports of the west coast of Ireland. A considerable export trade is carried on in grain, flour, pork and cattle; while coals, iron, timber and provisions are imported. There is a depth on the harbour bar of 15 ft. at low water, and there are commodious quays and basins. Vessels of 24 ft. draught have entered the harbour at high water. Harbour commissioners control the port. Brewing, flour-milling and saw-milling are the chief industries, and there is an important butter-market. Monthly fairs are held. Sligo is a centre of salmon and sea-fishing industries.

SLING, an implement for casting missiles, also, a hanging loop to support a wounded limb, a chain with hooks for raising or lowering heavy goods (from M.E. *slingen,* to fling, throw with a jerk, Icel. *slyngva, cf.* Ger. *schlingen,* to twist). The sling is probably the earliest device by which force and range were given to the arm of a thrower of missiles. Sling stones from the stone age are frequent. (*See* ARMS AND ARMOUR.) The type of weapon is of two kinds; the sling proper consists of a small strap or socket of leather or hide to which two cords are attached; the slinger holds the two ends in one hand, whirls the socket and missile rapidly round the head and, loosing one cord sharply, despatches the missile; the other type is the staff sling, in which the sling itself is attached to a short staff, held in both hands. This was used for heavier missiles, especially in siege operations during the middle ages. There are many references to slings and to slingers in the Bible; the left-handed slingers of Benjamin were famous (Judges xx. 16). The Assyrian monuments show the sling of the ordinary type and slingers were used in the ancient Egyptian army, but not before the 8th century B.C. The sling (Gr. σφενδόνη, Lat. *funda*) is not mentioned in Homer; Herodotus (vii. 158) speaks of the slingers in the army offered by Gelon to serve against the Persians; it seems to have been a weapon chiefly used by barbarian troops. The Acarnanians, however, were expert slingers (Thuc. ii. 81), and so also were the Achaeans, who later invented the sling which discharged a shaft with an iron bolt head (Livy xlii. 65, from Polybius). In the Roman army by the time of the Punic wars the slingers (funditores) were auxiliaries from Greece, Syria and Africa. The Balearic islanders, who were in Hannibal's army were always famous as slingers. In mediaeval times the sling was much used in the Frankish army, especially in defending trenches, while the staff-sling was used against fortifications in the 14th century. Till the 17th century, they were used to throw grenades.

SLINGING THE WEIGHT: *see* WEIGHT THROWING.

SLIPWAY. Inclined slipways, on which a vessel, resting in a cradle on wheels, can be drawn out of the water for cleaning or repairs, are used all over the world. In some American ports they are called *marine railways.* The contrivance is also known as a *patent-slip.* When gates and side-walls exclude the water from the upper part of the slipway, the contrivance is called a *slip-dock.* The word *slip* is applied to a paved causeway or *hard,* extending from high water to low tide level, on which small vessels may be hauled without the use of a cradle. *Graving slip* and *graving beach* are old terms for a hard or slip, and a beach on which vessels were placed for examination and graving when the tide receded. On *slips* in shipyards vessels are constructed and launched. The launching ways for lifeboats, over which the boat slides into the water or is hauled up, or with rails over which a launching trolley carrying the boat is run, are termed slipways. In American ports, for instance New York, the water spaces between piers, in which vessels berth, are called *slips* (*see* DOCKS). (N. G. G.)

SLIVEN, a town of southern Bulgaria, 105 m. E.N.E. of Philippopolis, picturesquely situated near the southern entrance of the trans-Balkan defile known as the Iron Gate. Pop. (1926), 29,235. Sliven lies on a branch of the Burgas-Philippopolis railway, and is the chief manufacturing centre in Bulgaria for the rough and fine homespuns known as *aba* and *shayak,* and its wine is locally celebrated. Extensive mulberry orchards have been planted in connection with the silk industry. Sliven, the Stlifanos of the Byzantine writers, was, on account of its strategic importance, frequently disputed in the middle ages between Byzantium and Bulgaria. After its capture by the Turks (1388) it was one of the privileged *voinik* towns (*see* BULGARIA); but these privileges were lost in the 16th century. In 1829 Sliven was occupied by the Russian army under Rudiger and Gorchakov.

SLOANE, SIR HANS (1660–1753), British collector and physician, was born on April 16, 1660, at Killyleagh in County Down, Ireland, where his father had settled at the head of a Scottish colony sent over by James I. He spent four years in the study of medicine in London, and then travelled through France, spending some time at Paris and Montpellier, taking his M.D. degree at the University of Orange in 1683. He returned to London with a considerable collection of plants and other curiosities, of which the former were sent to John Ray and utilized by him for his *History of Plants.* Sloane was elected into the Royal Society, and attracted the notice of Thomas Sydenham, who gave him valuable introductions to practice. In 1687 he went to Jamaica as physician in the suite of the duke of Albemarle. The duke died soon after landing, and Sloane's visit lasted only fifteen months; but during that time he got together about 800 new species of plants, the island being virgin ground to the botanist. Of these he published an elaborate catalogue in Latin in 1696; and at a later date (1707–25) he added two folio volumes. He became secretary to the Royal Society in 1693, and edited the *Philosophical Transactions* for 20 years.

In 1716 Sloane was created a baronet, being the first medical practitioner to receive an hereditary title, and in 1719 he became president of the College of Physicians, holding the office 16 years. In 1722 he was appointed physician-general to the army, and in 1727 first physician to George II. In 1727 also he succeeded Sir Isaac Newton in the presidential chair of the Royal Society; he retired from it at the age of 80. Sloane's memory survives more by his judicious investments than by anything that he contributed to the subject-matter of natural science or even of his own profession. His purchase of the manor of Chelsea in 1712 has perpetuated his memory in the name of a "place," a street and a

square. His great stroke as a collector was to acquire (by bequest, conditional on paying off certain debts) in 1701 the cabinet of William Courten, who had made collecting the business of his life. When Sloane retired from active work in 1741 his library and cabinet of curiosities, which he took with him from Bloomsbury to his house in Chelsea, had grown to be of unique value. On his death on Jan. 11, 1753, he bequeathed his books, manuscripts, prints, drawings, pictures, medals, coins, seals, cameos, and other curiosities to the nation, on condition that parliament should pay to his executors £20,000, which was a good deal less than the value of the collection. The bequest was accepted on those terms, and went to form the collection which was opened to the public at Bloomsbury as the British Museum in 1759 (*see* MUSEUMS). Among his other acts of munificence was his gift to the Apothecaries' Company of the botanical or physic garden, which they had rented from the Chelsea estate since 1673.

See Weld, *History of the Royal Society*, i. 450 (1848); and Munk, *Roll of the College of Physicians*, 2nd ed. i. 466 (1878).

SLOCUM, HENRY WARNER (1827–1894), American general, was born at Delphi, N.Y., on Sept. 24, 1827, and graduated at the U.S. Military Academy in 1852. When the Civil War broke out he became colonel of the 27th New York Volunteers, and was promoted major-general of volunteers (July 1862). He fought in all the Virginia campaigns from the first battle of Bull Run to Gettysburg, where he commanded the 12th Corps. With that corps he was transferred to the Tennessee valley, and took part in the battle of Chattanooga, and the Atlanta campaign, and succeeded to the command of the 20th Corps (late 11th and 12th). He resigned from the army in Sept. 1865, and was a Democratic representative in Congress in 1869–73 and again in 1883–85. He died at Brooklyn on April 14, 1894 where a monument to him by Frederick MacMonnies was unveiled, on May 30, 1905.

SLONIM, a small town of Poland, in the province of Nowogródek, 155 m. by rail S.E. of the city of Grodno and 20 m. from the railway from Moscow to Warsaw, on the high craggy banks of the Shchara. It derives its importance from the river, which is navigable and joins the Oginski canal, connecting the Niemen with the Dnieper.

SLOOP, a type of small sailing-vessels which have one mast rigged "fore and aft," carrying a mainsail, gaff-topsail, jib and fore staysail. There is little in rig to distinguish a sloop from a "cutter," and the terms are used indiscriminately; sometimes a distinction is drawn by a sloop having a fixed and a cutter a running bowsprit. In the sailing and early steam days of naval warfare, a "sloop" was a small corvette, ship-rigged, with all the guns mounted on the upper deck.

SLOTH, the name for a group of arboreal tropical American mammals belonging to the order Edentata (*q.v.*). Sloths are completely arboreal, living among the branches of trees, hanging beneath them, back downwards, and clinging with the hook-like organs to which the terminations of their limbs are reduced. When obliged to descend to the ground, which they rarely, if ever, do voluntarily, sloths (owing to the unequal length of their limbs and the peculiar conformation of their feet) crawl along a level surface with considerable difficulty. Though generally slow and inactive, they can on occasions travel with considerable rapidity along the branches, availing themselves of the swaying of the boughs by the wind to cross the larger gaps. They feed on leaves and young shoots and fruits. Sloths are nocturnal, silent and solitary animals, and produce but one young at birth. They show an almost reptilian tenacity of life. Sloths fall into two families, the Choloepidae, including only the unaus (*Choloepus*), with two functional toes on the fore-foot and three on the hind, and six or seven neck vertebrae; and the Bradypodidae (*Ai*), comprising the genera *Bradypus* and *Scaeopus*, with three functional toes on each foot and nine neck vertebrae. Sloths are remarkable in being the only mammals which do not invariably have seven neck vertebrae. Several other animals, such as the African potto-lemurs, and the Asiatic lorises, are popularly called sloths.

THE AI OR THREE-TOED SLOTH

SLOTTING MACHINES: *see* PLANING MACHINES.

SLOUGH, a market town in the Wycombe parliamentary division of Buckinghamshire, England, 18 m. W. of London by the Great Western railway and on a branch of the Grand Junction canal. Pop. of urban district (1931) 33,530.

SLOVAKIA, a province of Czechoslovakia covering an area of 18,895 sq.m., is largely mountainous territory within the western Carpathians but at its western and eastern ends encroaches upon the plains of the Morava-Danube and Tisa respectively. The mountain masses fall into four groups separated by lines of valleys and basins. From north to south these groups are, (1) the encircling arc, convex to the north, stretching from Devin on the Danube by the Little Carpathians, White Carpathians, West and East Beskids, to the Slovakia-Ruthenia frontier, (2) the ranges of Galgoc, Little Fatra and the High Tatra, (3) the Nitra, Great Fatra and Little Tatra groups and (4) the ranges and detached masses belonging to the Slovakian Ore Mts. (Slovenské Rudohoři). The outer girdle, composed of the sands and marls of the *flysch* formation, is the most continuous. Like the whole highland zone it shows a great variety of climates according to altitude and aspect and the only permissible generalisation is that conditions harden eastward. Human life in this zone is scattered and semi-nomadic concerned with forestry and shepherding on the slopes with small permanent settlements in the valleys. The central buttress of this arch is the High Tatra (*q.v.*) which overlooks southward the valley of the Váh; this is the major river of the highlands. Rising in the basin of Liptov on the northern flank of the Little Tatra it flows west through the basin of Turč and breaks across the Little Fatra and just beyond Žilina turns south to join the Danube at the port of Komárno. Adjoining the basin of Liptov is that of Spiš with the headwaters of the Hernad, another important route leading east and south to the Tisa. Parallel to the Váh the Hron separates groups (3) and (4) and supplies another highway to the Danube, important, but not comparable with the great Váh-Hernad corridor.

The inner groups of highland consist of a complex of crystalline rocks and altered Mesozoic limestones, highly folded and fractured and rich in ores and thermal springs. Each of the intermontane basins is settled and possesses industries based upon local supplies of raw material, *e.g.*, the working of flax, wool, wood and iron and the manufacture of pulp and glassware. Small supplies of lignite are obtained from Baňska Bystrica but the lack of coal is a disadvantage that is gradually being overcome by utilisation of the vast resources of water power. Where, as in the region of the middle Hron, volcanic outcrops give a softer tone to the landscape the cultivation of flax, hemp, fruit, rye and oats, with vine on the suitable slopes, assumes greater importance while from this district, once renowned for gold, silver and copper, certain ores are still obtained, *e.g.*, silver, manganese, antimony and iron. Baňska Štiavnica and Kremnica are the chief mining centres. In addition to industries mentioned there is widespread home-weaving and wood-carving, for commercial purposes, in the wooden houses of the highlands. Žilina and Košice are respectively the western and eastern centres of general trade. These are joined by railway, and are important junctions, the former for routes to Moravia, the Danube and via the Jablunka Pass to Silesia, the latter for routes to Hungary and Ruthenia. Apart from this main artery communication is poor, particularly between east and west, except in localised areas, *e.g.*, the High Tatra where small spas have been developed. Prešov in the Hernad valley, and Liptovský Svätý Mikulaš, the lumbering centre, are also important market towns.

The plainlands are part of the three great tectonic basins of Central Europe and approximate to them in general aspects. Gulfs of lowland stretch into the mountain zone along the courses of the Morava, Váh, Nitra, Hron, Hernad, Ondava and Laborce, with a narrow fringe of Tertiary and Recent deposits connecting them. The lowland is divisible into two parts, a western draining to the Danube, and an eastern to the Tisa. The former is a

fertile cereal zone passing through vineyards and orchards to upland pastures and gravitating towards Bratislava and Komárno. There a mild climate permits maize, wheat, barley, rye, fruit, wine, tobacco and sugar-beet in addition to the raising of cattle, horses and poultry. Brewing, milling, sugar-refining, tanning and the preparation of tobacco are the principal industries and they focus in Bratislava and its neighbourhood. The towns are pre-eminently cereal and cattle markets. Bratislava leads, but Sered is an important centre for timber trade, while the Váh valley, leading to the coal resources of Silesia, is a primary trade route.

Slovakia lags far behind the "Austrian" provinces of Czechoslovakia because for centuries it suffered neglect during the Hungarian hegemony. Transport and trade were centred upon Budapest and, though the province still looks in part to this city and the Danube for its natural markets, readjustment of outlook is slow but sure, and the Danube route between Bratislava and Parkáň gathers more and more of the trade while Prague gradually reasserts its traditional cultural and political leadership as communications improve and as the isolation of the highland, with its accompanying drag of primitive customs, traditions and costumes, is gradually overcome. Bratislava is the capital, the seat of a High Court of Justice and a Slovak University, but Košice fulfils certain similar functions for the eastern half of the province, *e.g.*, through its High Court of Justice. The total population of the province numbers 2,958,557, being about 69% Slovak, 21·5% Magyar, 4·7% German and 2·4% Jewish. The minorities, especially the Magyar, present a grave problem.

See E. Winter, *Die Deutschen in der Slowakei und in Karpathenrussland* (Münster, 1926); *see* also CZECHOSLOVAKIA.

SLOVAK LANGUAGE. The two languages of the Czechoslovak republic, namely Czech and Slovak (for which the combined designation Czechoslovak is in common use), are not identical, either in their literary form or in their dialects, in the same way as are Serb and Croat (to express which the compound Serbo-Croat is appropriately used). Slovak is, however, so closely allied to Czech that most scholars describe it as a dialect, although their view meets with many dissentient voices. In its early stages Czech presents great similarity with the sister language, which has retained with great fidelity the sound system of a past stage in the common development of the two languages, but Czech as written and spoken to-day in Bohemia diverges considerably from Slovak; the dialects spoken in Moravia, however, satisfactorily bridge over the differences, and only speakers of extreme dialects of Slovak are unintelligible to Czechs. The disagreement is least marked in vocabulary but appears prominently in the phonetics; in particular the itacism, so distinct a characteristic of Czech, is non-existent in Slovak, which has preserved the fuller diphthongs (*ia, ie, iu* etc.) of the other Slavonic languages; a further smaller point is that *dz,* from Common Slav *dj,* is used (as in Polish) where Czech has *z.* In one point only is there a divergence which goes back beyond the time of the common ancestry of the two languages; Slovak has not developed the *ř,* which is characteristic of Czech and in that language occurs since the beginning of its literature. The Slovak palatalization of *n, d, t* and *l* after *e,* which does not occur in modern literary Czech, is a further point of disagreement, although this would not be obvious from Slovak spelling which does not find it necessary to distinguish by diacritics consonants which are always softened in this position.

The alphabet is founded on the Czech, the accent is always on the first syllable and long vowels are indicated by acute accents. There are usually reckoned to be three groups of dialects, Western, Central and Eastern; the first being nearest to Czech, the last to Little Russian, while the Central dialects exhibit less decided features. The dialectical development shows some characteristics identical with those in South Slavonic and Russian. Not everywhere, for example, have C.S. *ŭ* and *ĭ* been confused, and instead of the *e,* which is the normal result in Slovak as in Czech, we find in Eastern dialects an *o* from the *ŭ,* thus agreeing with Russian. An agreement with South Slavonic is the occurrence of *raz-* and *la-* as well as *roz-* and *lo-* from C.S. *orz-* and *ol-*. Because of these and other phonetic and morphological reasons the grammarian Czambel, a keen opponent of the identity of Czech and Slovak, has asserted that Slovak should rightly be associated with South Slavonic. His views, which were influenced by considerations not wholly linguistic, have not found general acceptance.

Slovak books were rare before the War, but since the formation of a new and powerful State embracing the Czechs and the Slovaks, Slovak literature, which previously had had only local importance, bids fair to take a worthy place alongside of that of its better known partner. The *Survey of Modern Slovak Literature,* by Š Krčméry, in vol. vii., No. 19, pp. 160–170, of the *Slavonic Review* (London) gives useful literature statistics and a good account of the literature of the present century.

BIBLIOGRAPHY.—Dictionaries—J. Loos, *Wörterbuch der slovakischen, ungarischen und magyarischen Sprache* (Budapest, 1871); M. Kálal, *Slovenský Slovník* etc. (1924), written for Czechs, is most valuable, as dialect words are included. Grammar—S. Czambel, *Rukovät spisovnej reči slovenskej* (1919). This Handbook of Literary Slovak is the standard work. Czambel's other works, *e.g., Slováci a ich reč* (Budapest, 1903) and *Slovenská reč a jej miesto v rodine slovan. jazykov* (1906) are important for the dialects, but are biased; C. Dixon has written a *Slovak Grammar for English speaking Students* (Pittsburgh, 1896).

SLOVAKS, a Slav people mostly living in the eastern part of Czechoslovakia. The Slovaks are not much mixed: they have isolated settlements throughout the western half of Hungary where there is a Slovak minority numbering (1929) 142,000, or 1·8% of the total population. The Slovaks seem to have occupied this territory in the 5th or 6th century A.D. and to have stretched far to the south. They are a race of peasants, living almost exclusively upon the land, which they till after the most primitive methods. Where this does not yield sufficient, they wander as labourers and especially as tinkers even as far as South Russia. They are fond of music, and their songs have been collected.

SLOVENE LANGUAGE. Slovene, the most westerly language of the South Slavonic branch, is quite distinct from Slovak, which is spoken in the Eastern part of Czechoslovakia and belongs to the Western branch. The Slovenes inhabit those districts of Yugoslavia which border on Austria and Italy; the capital of their territory is Ljubljana (German form, Laibach), in the province of Carniola. Outside the borders of Yugoslavia, the language is spoken in the neighbourhood of Trieste, in the villages round Klagenfurt, the capital town of the Austrian province of Carinthia, and by colonists in North America and elsewhere.

Slovene is most closely allied to Serbo-Croat. The Croat dialect round Zagreb, which, like literary Slovene, uses *kaj* for "what," whereas literary Serbo-Croat has *što,* is in this and in other features, phonetic, morphological and lexicographical, a transition speech uniting the extreme ends of the kingdom of the Serbs, Croats and Slovenes. The only traces now left of the linguistic ties which must have once united Slovene with West Slavonic are found in the preservation by certain Carinthian or Hungarian-Slovene dialects of Common Slav *tl* and *dl* (which everywhere else in South Slavonic have become *l*), in the survival of a prefix *vy-* and in the development of the semivowels into *e.*

The phonetic feature which distinguishes Slovene from every other Slavonic language, is the change of C.S. *ǫ* to *o.* The treatment of C.S. *tj* and *dj,* which become *č* and *j,* is also characteristic but is not isolated, as the change of *tj* to *č* is also the normal but quite independent development in Russian, whilst *j* from *dj* occurs in the *ča* dialect of Serbo-Croat. The two half-vowels *ŭ* and *ĭ* which only in long accented syllables become *a,* normally develop into the mixed vowel ə always written *e,* except in purely philological works, thus being indistinguishable from the *e*'s derived from C.S. *ě* and *e.* Except in Carinthia, which in this as in numerous other respects goes entirely its own way, C.S. *ě* generally has become a closed *e.*

There are numerous other vowel changes, particularly in unaccented syllables, but their existence would not be suspected by casual examination of a Slovene literary text, as the orthography is conservative and consequently unphonetic. There are, for instance, at least four distinct *e* and *o* sounds to be kept apart in pronunciation. The distinction of intonation, which is a feature of Serbo-Croat, has been preserved in Slovene also, but the innovations made by each language have been so different that the results seldom agree. There are considerable variations in

Slovene itself as to which syllable receives the accent, but there is less divergence with regard to the nature of the accent: short syllables allow one intonation, while long syllables have two (a rising and a falling).

The grammatical system presents certain archaisms: thus the dual has been kept in nouns and verbs, and the supine has not been ousted by the competition of the infinitive.

The vocabulary and style of the literary language are typically Slavonic and show little admixture—such few loans as occur being chiefly from Russian, Czech and Serb; but owing to the age-long subjection of the Slovene people the spoken dialects have been much more seriously affected by German, Italian and Hungarian, and in some border dialects (*e.g.*, Carinthian) there is a danger that Slovene may degenerate into a jargon.

Although the dialectical variations are much more considerable than in the other languages, it is possible to distinguish two main groups: the more important is the South-western, which includes the lowland (*dolenjski*) dialect of Carniola—used by Primus Trubar, the creator of the Slovene literary language. The North-eastern group includes some of the dialects of Carinthia and of the districts beyond the river Múr, and for philological reasons is of high importance.

The spelling in current use is modelled on Czech, but among the Slovenes of Hungary, where the literary use of the dialect was to some extent encouraged for religious purposes, the Hungarian system prevailed.

Bibliography.—The most complete dictionary is that of Mr. Pleteršnik (*Slovensko-nemški slovar,* Ljubljana, 2 vols., 1894–95) which marks the quality and intonation of the vowels. There are numerous smaller dictionaries (Slovene-French, Sl.-Italian, Sl.-Czech, etc.), but none has as yet appeared in which the Slovene words are translated into English. Grammars—*The Historical Grammar of the Slovene Language* (in Slovene) by F. Ramovš (Part II. on the consonants has so far appeared; Ljubljana, 1924) will be a monumental work when completed. A useful small work (in Slovene) is A. Breznik's *Slov. Gram. for Middle Schools* (Prevalje, 1921). Philological works —The *Ĉasopis za slov. jezik, književnost in zgodovino* (Periodical for Slov. Lang., Lit. and History, Ljubljana, 1920, *seq.*) is the chief review. Surveys of works on Slovene are issued with every number of the *Revue des Études slaves* (Paris). The *Jezikoslovni Spisi* (Philological Essays) of A. Breznik (Ljubljana, 1916–19) are valuable. *Les formes du duel en Slovène* and the accompanying *Atlas Linguistique,* by L. Tesnière (Paris, 1925) cover entirely new ground for any Slav language. Literature—"A Survey of Modern Slovene Literature" (*Slavonic Review*, vol. vi., pp. 618–634, 1928), by J. Vidmar, deals with the greatest names of the last hundred years.

SLOVENES, a Slavonic people. The chief mass of them lives in Yugoslavia, occupying Slovenia and the adjoining sections of Yugoslavia. The boundary on the east is difficult to fix, as the linguistic transition is gradual and a certain dialect of Croatian (marked by the use of *kaj*="what") may have been originally Slovene.

SLOW-WORM or **BLIND-WORM** (*Anguis fragilis*), a legless lizard, which is neither slow nor blind, nor is it a worm. The slow-worm is fairly common in Great Britain and ranges across Europe to western Asia. On account of the absence of legs it is often mistaken for a snake. It is quite harmless, feeding on worms, slugs, etc. Like many other lizards, it can break off its tail if seized thereby. (*See* Reptiles.)

SLUG. The name generally given to the members of a group of land molluscs related to the land snails but lacking an external shell. They include the families Limacidae and Arionidae of the Pulmonate Gastropoda. There are several other groups of less familiar Pulmonates (*e.g.*, the Daudebardiidae, Veronicellidae and Rathousiidae) which may be called "slugs." The name is indeed extended to all shell-less elongate Gastropods such as the "sea-slugs" (Nudibranchia: Oncidiidae).

The common slugs (*e.g.*, the black slug, *Arion ater* and *Agriolimax agrestis,* the field slug) are placed in the sub-order Stylommatophora of the Pulmonata. The shell is wholly internal and may be absent. The mantle is seen as a shield-shaped projection at the anterior end. In the living animal a small contractile orifice is seen on the right-hand edge of the mantle. This is the pneumostome or respiratory orifice through which air is drawn into the lung-like mantle-cavity. In *Limax* the shell is persistent, but it has no spiral apex; in *Arion* it is very degenerate and is reduced to a few calcareous granules. In the tropical Veronicellidae and Rathousiidae it is entirely absent. Most of the land slugs have two pairs of tentacles; the eyes are borne on the extremities of the posterior pair and the anterior pair carries the tactile organs.

A typical land slug such as *Arion ater* inhabits woods, fields, gardens, hedgerows and wilder places. It is more or less omnivorous and Ellis states that it feeds on green leaves, fruit, fungi and dead animal and vegetable matter. The sea-slugs are principally represented by a number of completely naked genera of Nudibranchiata Gastropods. The most striking of them are the Eolids, which are small, often brightly coloured animals. They are found in shallow waters and in rocky pools. (For the peculiar function of the cnidosacs of these animals, *see* Gastropoda.) Certain of the Oncidiidae are remarkable for the numerous eyes scattered over the dorsal surface which are stated to be a special adaptation in relation to the attacks of a littoral fish (*Periophthalmus*) which preys upon them. (G. C. R.)

SLUM. The expressions "Slum" and "Slum Conditions" scarcely admit of any exact definition. For practical purposes they are recognized as consisting of home conditions in which, owing either to the dilapidated, insanitary or unsuitable character of the housing provision, or to the overcrowding to which it is subjected, the conduct of healthy and decent family life is impossible. Such conditions exist even in the pleasantest villages, as well as in the cities and towns, and in all cases they are found to incur similar consequences to the health of their inhabitants, especially to the children.

The slum as found in the United States is fully discussed in the article Housing, U.S. section. The article below covers the slum conditions in Great Britain. For the progress of the work of slum clearance, *see* the par. under that head *s.v.* Housing. *See* also Social Architecture.

Origin and Character.—Insanitary houses consist substantially of two main groups, and the distribution of the types varies very much in different districts according to their past industrial history and housing standards. The first group consists of those houses in which the housing provision itself is of an insufficient standard with regard both to accommodation and conveniences; and the second consists of those which, whilst primarily suitable in themselves, have become what they are owing to a change in their manner of use. In these cases, for the most part, the houses have become split up and let out in separate tenements without material adaptations, so that what was originally a dwelling for one family has now come to be occupied by four, five or sometimes a larger number of families.

The first group includes most of the dilapidated and insanitary country cottages, and it is widely represented in the older cities, and in the towns that underwent rapid industrial development during the nineteenth century. It is very general also throughout Scotland. In the older cities and towns the houses are usually small and have been built in yards, alleys and courts, or on any other available space, without much semblance of order, or regard to light, ventilation and sanitation. In the more industrial towns they consist chiefly of closely-packed, back-to-back, houses, and represent the first unregulated exploits of the jerry-builder. The city of Leeds provides perhaps the most conspicuous example of this last class, and in Mr. Neville Chamberlain's Report to the Ministry of Health of the "Unhealthy Areas committee of 1921," it is recorded that this city has 72,000 back-to-back houses, which consist of 12,000 that are fairly substantial; of 27,000 built in blocks of eight, opening directly on to the street with the sanitary conveniences for each pair of blocks (16 houses) provided between them and only approached by the street; and of a further 33,000 houses which are described as "built in long continuous blocks opening directly on to the street . . . crammed together at the rate of 70 to 80 per acre"; in regard to which it is added: "It is difficult to suggest any method of dealing with them satisfactorily short of complete clearance." The Royal Commission on Housing in Scotland found that 539,000 houses, or rather more than half the houses in that country, had not more than two rooms.

The second group of slum houses is especially widely represented

in London, where, in the course of time, the character of the older and more closely-built districts has altered with the growth of population and the development of outside areas. There are miles of houses in London, now let as tenements, which originally consisted of single family dwellings—usually with a basement kitchen that is commonly the only room provided with a cooking range. In other respects also, despite the efforts of the sanitary authorities, the domestic and sanitary arrangements are commonly of a very inadequate character. An analysis of a group of houses of this kind in a typical street in the borough of Shoreditch yielded the following results in summary:

House	Number of lettings	Population	Number of water connections in the house	Number of water taps in the house
1 . .	6	20	2	2
2 . .	4	27	2	2
3 . .	4	24	2	2
4 . .	6	13	1	1
5 . .	8	10	1	2
6 . .	8	34	2	1
7 . .	5	29	2	1
8 . .	7	29	2	1
9 . .	7	34	2	1
10 . .	4	18	2	2
Totals .	59	238	18	15

In other, better-to-do, districts, such as Westminster, there are many cellar dwellings in houses or buildings which are not otherwise let in tenements.

The number of people affected by these two groups of housing conditions is not easy to ascertain, as the returns of the numbers of insanitary houses do not all provide the population statistics; whilst the returns of those that are styled "overcrowded" do not include all the dilapidated cottages and other bad houses which are not technically overcrowded. The standard of "overcrowding" adopted in England and Wales is "more than two persons" for each room, whilst in Scotland it is "more than three persons" for each room. Accepting these qualifications, however, there appear to be about a million houses in England and Wales that consist of not more than two rooms, and there are rather more than three million people returned as overcrowded. In Scotland, despite the fact that the overcrowding standard is lower, the proportion of those inhabiting unsatisfactory dwellings is greater. In the city of Glasgow, for example, 470,000 people, or more than 60 per cent. of the total population of the city live in homes of not more than two rooms, and nearly a quarter of them have only one room. In Scotland, as a whole, there are 2¼ million people, or somewhat less than half the population, living in two rooms or less, and of these, 400,000 have one room only. The Royal Commission found that at least 50 per cent. of the one-roomed houses, and 15 per cent. of the two-roomed houses, were so insanitary and dilapidated that they ought to be replaced.

Effects of Slum Life.—The effect upon the inhabitants of life under such conditions is difficult to imagine by those who have not examined them at first hand. The fact is that one or two gloomy rooms have to provide for all the purposes and events of family life. The character of the houses themselves is thus described in the Report of the Scottish Board of Health Commissioners on Glasgow Housing for 1926:

> The majority of the houses were dark, many of the tenants having to burn gas all day, winter and summer. Large numbers of tenements were built in the middle of hollow squares, hard up against high buildings on all sides, with no proper ventilation or light. Damp was present everywhere, the walls and ceilings in a large number of houses being literally soaking. Everywhere we noticed an almost total lack of sanitation, conveniences being few and for the most part out of repair, and in some cases leaking down the stairs and even into the houses. . . . Dilapidation is rife throughout the areas. Ceilings are falling down, woodwork is rotting away, there are holes in the walls of houses through which the street can be seen, and the plaster-work of the walls is loose and broken. The houses are a hunting-ground for vermin of every description. Fleas, of course, abound, but we found also that practically every property we inspected was absolutely bug-ridden. The tenants complained that they could get no peace from these pests, which drop upon their faces and crawl over their persons and beds at night, and which fall into their food during the day. The food itself will not keep in many of these tenements . . . owing to the damp and verminous condition of the holes in the walls in which it is kept.

Health statistics generally, mortality rates, the statistics of tuberculosis infection, of the defects of school children and of the analysis of the sicknesses of insured persons, all reveal, in common, the damaging results of life under these conditions. The following comparable table, as ascertained by Dr. Robertson, medical officer of health for Birmingham, for an overcrowded and a well-built area, seems fairly to represent the conditions generally found:

	Slum area	Well-built area
	%	%
Death rate	20	10
Infant death rate	152	69
Tuberculosis death rate	2·3	·79
Infantile diarrhoea under the age of 2 years, per 1,000	42	6

Remedial Methods.—A certain proportion of the bad houses is capable of improvement or restoration, although they would only then serve for a smaller number of inhabitants. In a very large proportion of these cases, however, the cost of repair or re-construction is so great that a private owner cannot look to regain it in the form of increased rent and this necessarily imposes a limit upon what can be expected. In many cases, also, the owners or leaseholders of poor houses are themselves people of small means and cannot command the necessary capital. Nevertheless much improvement has been effected by some local authorities, who have systematically and reasonably used their powers, to obtain improvements over a period of years. For example, the city of Manchester has finally secured the abolition of cellar dwellings, and in many towns a great reduction, or even the elimination, of back-to-back houses has been obtained.

The conduct of slum reclamation must necessarily be piecemeal, as it is impossible to dis-house any great number of people at a time during the process of reconstruction. The city of Liverpool presents, perhaps, the most conspicuous example of the valuable results obtained in the course of time by the progressive acquisition and reconstruction of bad portions of the city; where, by the accommodation of the dis-housed people in flats erected for their accommodation, it has been possible to adjust operations so as to avoid intensification of the pressure on surrounding streets.

Nevertheless, the policy of waiting until an area has become condemned until it can be acquired and so dealt with, has proved to be too limited to allow of general success, and the following conditions—chiefly based on the Report of the Unhealthy Areas Committee—seem to be essential: (1) A full use should continue to be made of all existing sanitary powers, in addition to the continued provision of new houses in open parts. (2) Unnecessary demolition should be restrained by the grant of power to "declare an area congested" and to prohibit the demolition of houses and the erection of other buildings therein without license. (3) Clearance and reconstruction should be a part of a comprehensive and carefully prepared planning scheme affecting not only the area itself but adjacent parts of the town or country. (4) The local authority should be competent to undertake sufficiently extensive acquisition so as to enable it to obtain a better ultimate return by the proper disposition on the ground, of dwellings and of commercial and business premises. (5) Pending such acquisition and reconstruction, authorities should be competent to "declare areas unhealthy" and to purchase them with the purpose of improving the housing conditions under a scheme of collective management and improvement. (6) Finally, apart from various technical proposals as to the methods of acquisition and compensation, it is agreed that in London and the larger cities there should be a combination of authorities responsible for the supervision and execution of reconstruction schemes, for the reasons that the district afflicted with slums is usually poor and unable to bear

the burden, and that an adequate town-planning scheme involves questions of transport and development which extend beyond the boundaries of individual authorities.

SLUMP: *see* Trade Cycle.

SLUTZK, formerly Pavlovsk, a town of Russia on the Slavyanka river, 17 m. south of Leningrad, in 59° 40′ N., 30° 25′ E. Pop. (1926) 6,231. It was a former summer resort of the aristocracy, and contains many villas and palaces, now used either as holiday colonies or children's schools, or converted into museums. Among the more famous sights are the castle (1782–1803), situated in a beautiful park, the English Pavlovsk park, laid out by Cameron, the Pavilion of Roses, built by Rossi in 1812 and formerly covered with roses, where Alexander I. celebrated his victory over Napoleon in 1814.

See *Guide to the Soviet Union* (Moscow, 1925, in English).

SLUYS (SLOIS), BATTLE OF, fought on June 24, 1340, one of the two sea-fights in which King Edward III. of England commanded in person, the other being that called Espagnols-sur-Mer (*q.v.*). The place of the encounter was in front of the town of Sluis, Sluys, or in French Écluse, on the inlet between West Flanders and Zeeland. In the middle of the 14th century this was an open roadstead capable of holding large fleets. It has now been silted up by the river Eede. A French fleet, which the king, in a letter to his son Edward the Black Prince, puts at 190 sail, had been collected in preparation for an invasion of England. It was under the command of Hue Quiéret, admiral for the king of France, and of Nicholas Béhuchet, who had been one of the king's treasurers, and was probably a lawyer. Part of the fleet consisted of Genoese galleys serving as mercenaries under the command of Barbavera.

Although English historians speak of King Edward's fleet as inferior in number to the French, it is certain that he sailed from Orwell on June 22 with 200 sail, and that he was joined on the coast of Flanders by his admiral for the North Sea, Sir Robert Morley, with 50 others. Some of this swarm of vessels were no doubt mere transports, for the king brought with him the household of his queen, Philippa of Hainault, who was then at Bruges. Edward anchored at Blankenberghe on the afternoon of the 23rd and sent three squires to reconnoitre the position of the French. The Genoese Barbavera advised his colleagues to go to sea, but Béhuchet, who as constable exercised the general command, refused to leave the anchorage. He probably wished to occupy it in order to bar the king's road to Bruges. The disposition of the French was made in accordance with the usual mediaeval tactics of a fleet fighting on the defensive. Quiéret and Béhuchet formed their force into three or four lines, with the ships tied to one another, and with a few of the largest stationed in front as outposts.

King Edward entered the roadstead on the morning of the 24th, and after manoeuvring to place his ships to windward, and to bring the sun behind him, attacked. The battle was a long succession of hand-to-hand conflicts to board or to repel boarders. King Edward makes no mention of any actual help given him by his Flemish allies, though he says they were willing, but the French say that they joined after dark. They also assert that the king was wounded by Béhuchet, but this is not certain, and there is no testimony save a legendary one for a personal encounter between him and the French commander, though it would not be improbable.

The battle ended with the almost total destruction of the French. Quiéret was slain, and Béhuchet is said to have been hanged by King Edward's orders. Barbavera escaped to sea with his squadron on the morning of the 25th, carrying off two English prizes. After the battle King Edward remained at anchor several days, and it is probable that his fleet had suffered heavily.

The story of the battle of Sluys is told from the English side by Sir Harris Nicolas, in his *History of the Royal Navy*, vol. ii. (London, 1847); and from the French side by M. C. de la Roncière, *Histoire de la marine française*, vol. i. (Paris, 1899). Both make copious references to original sources.

(D. H.)

SMALL ARMS, THE DEVELOPMENT OF. Roger Bacon recorded in the year 1248 the composition of gunpowder, and it is almost certain that he was its discoverer. The Chinese and other Eastern nations are believed to have used at an earlier date mixtures which were incendiary but not explosive.

Early History.—There is no trace of fire-arms before A.D. 1300, and it is believed that the first to use gunpowder for the propulsion of missiles was Bernard Schwarz, a German monk. The earliest missiles were arrows padded out to fit the bores of these weapons. The hand-gun, as opposed to the cannon, was derived from the latter and does not appear to have existed until late in the 14th century. At first it consisted of a short iron tube, prolonged behind into a rod which was used to manipulate it, and which was hitched under the arm when the piece was fired. The charge was inserted from the muzzle and when in position was ignited by applying a wick match to a touch-hole on the upper side of the rear end of the tube. Later, the touch-hole was made on the side of the tube, the priming pan being conveniently placed. The match was held in a hinged fork mounted on the stock, enabling it to be brought into contact with the powder in the priming pan. This match-lock, so arranged, was known as the "harquebus." It is easy to understand that this smouldering wick match and the powder in the priming pan were affected by rain, etc., so adding to the probability of missfires.

The next development was the wheel-lock. This was produced in Germany early in the 16th century and was used first with sporting weapons and pistols. In it, the cock was armed with pyrites, which, when lowered, pressed against the serrated edge of a steel wheel projecting through the bottom of the priming pan. When the trigger was pulled, the wheel revolved and sparks were struck, which ignited the priming in the pan. Thus was eliminated one component, *i.e.*, the match, so subject to the effect of damp.

Like the wheel-lock, rifling (Ger. *riffeln*, to groove), of the barrel was introduced early in the 16th century, some attributing the invention to Gaspard Koller, a gunmaker of Vienna, others to August Kotter, an armourer of Nuremberg. The advantages derived from spinning a projectile had been known from early times, but in those days difficulty in applying the principle to fire-arms was appreciable. Spiral grooving would spin a ball if the ball were gripped by it firmly from breech to muzzle. However, as the powder was foul and made of impure ingredients, it left a crust in the bore after each shot was fired, which necessitated the use of a ramrod to drive the next ball home into position against the charge. This was a laborious process and caused delay, so although rifling came into use on the Continent for sporting weapons, and pistols, etc., for target purposes, where accuracy was more important than rapidity of fire, many years passed before any material success attended it.

Not until about 150 years after its invention was the wheel-lock superseded by what eventually became the flint-lock. It also had a cock holding pyrites, and when the cock fell this struck against a piece of steel, throwing sparks into the priming pan. Flint was substituted for pyrites, in or about the year 1600, and the flint-lock approached its perfection when it was made so that the cock in falling not only struck the necessary sparks but simultaneously uncovered the priming pan which had up to that moment been protected against accidental dispersion and the weather. Later the flint-lock was adopted by the British army and this was the weapon in the hands of the troops not only during Marlborough's campaigns, but also those of Wellington.

Rifles: Later Developments.—As regards rifled barrels, no considerable use was made of the rifle in France till 1830, when the Chasseurs d'Orléans were armed with it for the invasion of Algiers. The American settlers had learnt to use their hunting rifles with such effect that, during the American War of Independence, the British army learnt that the only effective rejoinder was to pit rifle against rifle. The British Government consequently subsidized Continental Jägers armed with rifles to oppose the American riflemen. After the war these troops were dispersed, and, though they are represented by the 60th King's Royal Rifles, the senior rifle corps in the British army is the Rifle Brigade which was raised in 1800 as the 95th Regiment, and armed with a flint-lock weapon known as the "Baker rifle," weighing 9½ lb. The barrel was 30 in. long, the bore ·625 with seven grooves, making one quarter turn in its length, and sighted for 100 and

200 yards. Baker was a gunmaker in Whitechapel. A wooden mallet was at first supplied to force the ball down the barrel, which was loaded with great difficulty.

Percussion Ignition.—Shortly after this a development took place, which, after gunpowder, was probably the most important advance in the history of all fire-arms, namely, the invention of the percussion system of ignition by Alexander Forsyth. Had such a development not been made, rapid continuous fire from any type of gun would probably have remained an impossibility. Starting in 1793, Forsyth, after many trials and experiments, sometimes dangerous, eventually perfected a lock which was applied to a fowling-piece in 1805, and which proved successful. His principle was to employ a detonating powder, which, when hit a smart blow by a hammer, flashed through the touch-hole and ignited the powder in the barrel. He perfected the details of his system and mechanism, and in 1807 claimed that "the Forsyth patent gun-lock is entirely different from the common gun-lock. It produces inflammation by means of percussion, and supersedes the use of flints. Its principal advantages are, the rapid and complete inflammation of the whole charge of gunpowder in the chamber of the barrel, the prevention of the loss of force through the touch-hole, perfect security against rain or damp in the priming, no flash from the pan and less risk of accidental discharge of the piece," etc., etc. (*See* Maj.-Gen. Reid, *Alexander John Forsyth.*)

The percussion cap, which was a natural development of this system came into use about 1820. It was a great improvement. Though Forsyth's system was adopted fairly generally for fowling-pieces, it was viewed with suspicion by the military authorities, until, in 1834, his invention was officially tested by firing 6,000 rounds from six flint-locks, and a similar number from six percussion muskets in all weathers. The superiority of the percussion system was completely established and led, in 1836, to the arming of a second battalion of the Rifle Brigade with an improved weapon, the ·704 Brunswick rifle, in which this percussion system was embodied.

The Brunswick Rifle.—In this rifle barrel were two grooves, making one turn in its 30 in. of length, the twist thus being four times steeper than that in the Baker rifle. The projectile it fired was a ball, round which was a belt. The latter, travelling in the grooves, imparted a spin to the bullet. One of the advantages claimed for this rifle was that a more rapid spin could be imparted to the bullet, as, owing to its belt working in the grooves, there was no fear of this leaden ball stripping or riding over the rifling. Much thought was devoted to the questions of the most effective twist, and the best number of grooves, coupled with the desirability of increasing rapidity of loading by devising a projectile which would pass easily down the bore and would yet, when fired, expand into the grooving.

In 1826, Delvigne, a French infantry officer, invented a chamber with abrupt shoulders on which the spherical bullet was rammed down until, expanding, it fitted the grooves. The line of development which the bullets took was twofold, namely, making them long with rounded or ogival noses, and also cupping their bases, with or without metal or wooden plugs positioned inside these cups. The gases on meeting these bases expanded the cupped bullet, or else forced the plug to expand the bases of the bullet, and so sealed the bore.

The Minié Rifle.—The "Minié" rifle, in which this bullet was first demonstrated, had no devices in the bore for expanding the bullet, reliance being placed on the action of the gas pressure on the base of the bullet to "set up" the base, and so seal the bore. This principle has been adopted practically ever since for small arms. The Minié rifle was a success and was adopted by France and Belgium, the United States, also by the British Government in 1850–51, and was entitled the Regulation Minié Musket. This rifle was employed in the Kaffir War of 1851 and also in the Crimea. Its weight with bayonet was 10 lb. 8¾ oz., the barrel 39 in. long, having four grooves making one turn in 72 in., and the bore was ·702 inches. It was sighted for from 100 to 1,000 yards.

Dreyse Needle Gun.—Ten years before the adoption of the Minié rifle, however, Prussia led the way by adopting the Dreyse needle gun. This was a breech-loading bolt action, provided with a long needle carried in a slender rod which was actuated by a surrounding spring. On pulling the trigger the rod flew forward, and the needle, passing through a guide in the front of the bolt, struck a disc of detonating material, so igniting the charge. This was the system initiated in England by Forsyth in 1805. This early pattern suffered certain defects; for example, after a few rounds, owing to the escape of gas and flame between the breech and bolt, the rifleman could not continue firing from the shoulder. Also, the needles rusted and broke; yet the gain in rapidity of loading was considered to outweigh greatly the above defects, and this rifle was the general arm of the Prussian and German troops in the wars of 1848, 1866 and 1870.

The Enfield Rifle.—In 1855, the Enfield rifle, made in the Royal Small Arms Factory, was introduced into the British army, after it had been tested against others made by private firms, to which it was found to be superior; and in the Crimea it superseded the rifled musket and the Minié. In turn the Enfield rifle was tried at Hythe against one made under the auspices of Sir Joseph Whitworth in 1857, which proved to be much superior. This Whitworth rifle had a hexagonal bore of ·45 in. calibre rifled to one turn in 20 inches. Induced by the commander-in-chief, Lord Hardinge, Sir Joseph Whitworth had devoted himself to a long series of experiments to investigate the subject of rifling, which culminated in his demonstrating the advantages to be gained from spiral rifling, a small bore and an elongated projectile. Despite this, the Whitworth rifle, which embodied these features, was never generally introduced into the service, although advantage was taken of the lessons he taught. Between the years 1857 and 1861 four breech-loading carbines were introduced into the cavalry experimentally. These were Sharp's, Terry's, Green's and Westley-Richard's, and as a result of the opinions formed, and the example set by Prussia, committees were appointed in 1864 and 1866 by the British War Office, to report on breech-loading arms. In addition, gunmakers were invited to forward proposals for the conversion of the 1853 pattern Enfield rifle to the breech-loading method. Some 50 different suggestions for this conversion were investigated, and the one finally selected was that of Jacob Snider, an American, which was adopted in 1867.

The Snider Rifle.—Snider's conversion consisted of a breech-block, hinged to swing up and out to the right. Through this block passed the firing pin, with which was a spring holding the pin to the rear so that its end protruded towards the hammer. When the hammer fell by pulling the trigger, it drove the pin forward so that its point struck the percussion cap. The block, when hinged down, was kept closed by a spring and cam action underneath. With the converted Enfield rifle was employed the cartridge invented by Col. Boxer. This cartridge was made up of coiled metal and had a percussion cap in the centre of its base. The advantage derived from this cartridge was that, under the gas pressure of the explosion, the cartridge expanded and so sealed the breech against escape of gas or flame; also after discharge the metal contracted, thus permitting simple and quick extraction of the case. In 1866 France adopted the bolt action Chassepot, used later in the Franco-German War. Shortly afterwards, Sweden adopted the Hagström, Russia the Carte and Italy the Carcano rifles. All these were breech-loaders using paper cartridges containing their own means of ignition. The conversion of the Enfield to the Snider was admittedly a temporary expedient, and soon after its completion steps were taken to procure a new design of rifle. Having received rifles from many different firms and factories, a model was selected which embodied an action submitted by Martini, an American, as modified by the Royal Small Arms Factory, in combination with a barrel put forward by Henry, with which the Boxer cartridge was to be used. This was subsequently known as the Martini-Henry.

The Martini-Henry Rifle.—The bullet first used weighed 480 grains and was lubricated by a wax wad between it and the powder. The bore was ·45 in., with seven grooves twisting one turn in 22 in., and, after further improvement of both the car-

tridge and the action, this rifle was adopted in 1871, though at the time it was realized that its ejection was not sufficiently powerful. Its general design was a breech-block, hinged in rear, and containing a firing pin and spring. A lever underneath the butt, when operated by hand, moved this breech-block in a vertical arc round its axis, so opening and closing the breech, and at the same time cocking the hammer. In 1884–85 Germany and France converted their single-loading rifles to embody a magazine, consisting of a tube in the fore-end underneath the barrel. These improvements, and further experiments in England with reduced calibres, led the appropriate committee to recommend first the adoption of the small calibre, and later a magazine rifle of ·303 bore embodying the Lee breech bolt action and box magazine, with rifling of the Metford system, namely, seven shallow grooves twisting one turn in ten inches.

The Lee-Metford and Lee-Enfield Rifles.—This rifle became known as the Lee-Metford, and was adopted in 1888. Later, when cordite was introduced in 1893, the erosive effect of this propellent was found to be such that the rifling quickly disappeared. For this reason, a system of rifling known as the Enfield was adopted, which had five grooves of square section, twisting one turn in 10 in. and which has not since been changed for the British army rifle. On the change to this system of grooves, the rifle was re-named the Lee-Enfield. This was the rifle used in the Boer War of 1899–1902. A Lee-Enfield carbine, with a barrel shortened to reduce weight, was the firearm of the cavalry in that war. This shortening of the barrel caused a portion of the cordite charge to be unconsumed before the bullet left the bore, and the velocity of this weapon was appreciably below that of the rifle, which necessitated greater elevation of the carbine for corresponding ranges. The trajectories of the bullets fired from the carbine being very high and curved, the difficulty of hitting the mark was increased. In consequence, after that war a compromise was made, and a rifle, some 1 lb. 2½ oz. lighter, and 4½ in. shorter, was introduced for both cavalry and infantry in lieu of the Lee-Enfield. This was called the Short Magazine Lee-Enfield Mk. 1, and is, with minor improvements, the weapon which is still in the hands of the troops.

In general quite similar developments may be noticed in the military small arms of other principal nations. Thus in the United States of America the flint lock, muzzle loading rifle was introduced by the Germans and Swiss who settled in Pennsylvania, and starting as early as 1730 it became the chosen weapon of the frontiersman, and was used to some extent in the American Revolution and in the War of 1812. Its calibre varied from about ·32-inch to about ·60-inch, and its barrel was usually very long. It was popularly known as the "Kentucky" rifle. After the Revolution the government contracted from time to time for a small supply of quite similar rifles for military use until 1842 when the manufacture of military rifles was undertaken at the national armory at Springfield, Mass.

The majority of Continental troops in the Revolution were armed with the Charleville musket, Model of 1763, purchased from the French. This was a smooth bore, muzzle loading, flint lock weapon of ·69 calibre, firing a spherical lead ball weighing about 440 grains. An almost exact copy of this musket, known as the Model 1799, was afterwards manufactured at Springfield Armory, and was the first standard military small arm manufactured by the United States for its forces. This musket, with minor improvements, remained in general use until 1842, when a muzzle loading percussion lock rifle of ·58 calibre shooting a spherical bullet was adopted, this year seeing the definite adoption of both rifle and percussion lock by the United States forces. Certain minor improvements continued, the principal weapon used in the Civil War being the Model of 1861, a percussion lock muzzle loading rifle of ·58 calibre, shooting a 480 grain conical Minié bullet.

The year 1866 saw the adoption of the Springfield breech loading rifle, shooting a centre-fire metallic cartridge of ·50 calibre using a grooved and lubricated lead bullet of 450 grains with a powder charge of 70 grains of black powder, the muzzle velocity being 1,240 feet per second. In 1873 this Springfield breech loading, single shot rifle was further improved and the calibre was changed to ·45. The new cartridge, remaining the standard until 1892, consisted of a centre fire brass case containing 70 grains of F.G. black powder and a conical, grooved, lubricated, lead bullet of either 405 or 500 grains, the 405 grain bullet being usually used in the short barreled cavalry carbine, and the 500 grain bullet in the infantry rifle. The muzzle velocity of the rifle with 500 grain bullet was 1,315 feet per second.

In 1892 a small bore, smokeless powder, magazine rifle was adopted and manufactured at Springfield Armory. The breech action was a modification of the Krag-Jorgensen, the magazine containing 5 rounds. The cartridge was of ·30 calibre containing a 220 grain bullet with cupro-nickel jacket and lead core, and a charge of nitro-glycerine smokeless powder sufficient to give a muzzle velocity of 1,960 feet per second. This rifle was improved several times, chiefly to facilitate production, the later models being known as the Model 1896 and the Model 1898.

The Spanish-American war demonstrated the need of a higher muzzle velocity to flatten trajectory, and of a quicker method of charging the magazine. Accordingly a new rifle, the Model 1903, was developed at Springfield Armory, being a modification of the Mauser, the magazine being charged with a clip of 5 cartridges. This rifle was first issued to troops in 1905. The cartridge of the rimless type contained a 220 grain bullet, and gave a muzzle velocity of 2,300 feet per second. In 1906 the cartridge was changed to contain a 150 grain sharp pointed bullet with muzzle velocity of 2,700 feet per second, known as the Model 1906 cartridge, and all existing rifles were rechambered for the new cartridge. Again in 1926 the bullet was changed to one of boat tail or stream line form, weighing 172 grains and jacketed with a composition of copper 90 parts, zinc 10 parts, to avoid metallic fouling. The new cartridge, used in both rifles and machine guns, is known as the ·30 calibre Mark I., and gives a muzzle velocity of 2,660 feet per second. The Model 1903 rifle remains the standard service rifle of all the United States military forces.

During the World War the facilities for the manufacture of the Model 1903 rifle were not sufficient to produce it in the quantities required. Several large factories had been manufacturing the Enfield Model 1914 rifle under contract for the British government. It was possible to slightly change the 1914 rifle so that it would use the United States ·30 calibre Model of 1906 cartridge. The modified rifle, known as the U.S. Rifle Model of 1917, was manufactured in large quantities in these factories and about half of the United States troops in France were armed with it, the remainder using the Model 1903 rifle.

DEVELOPMENT OF THE MACHINE GUN

Side by side with this advance in the design of rifles, and starting from an early date in the history of small arms, there was taking place a gradual development of the mechanical means of producing an ever-increasing volume of fire. Until the development of the Spanish arquebus (about 1520) infantry fire was, from lack of range, inaccuracy, and slowness of delivery almost ineffective. In those days, cavalry was the battle-winning arm, and the cavalry charge the decisive manoeuvre. Weapons propelling projectiles being then so unfitted to repel these rapid moving cavalry charges, reliance was placed by the defenders on masses of pikes for close defence rather than on the fire-arm. Accordingly, for the attackers arose the problem of how best to overcome or counteract these masses of pikes. The first solution attempted was the "cart with gonnes" known as *ribaudequins*. In these, the barrels were connected to a combustion box common to all, and on ignition of the powder in the box, all the barrels were fired in a volley. Though originally intended to assist in the attack, these weapons also lent themselves to the defence. An historical instance of the employment in battle of these *ribaudequins* is that of Pedro Navarro, who commanded the Spanish forces at the battle of Ravenna in 1512. He disposed in front of his infantry, 30 carts, on each of which several large arquebuses were mounted. Thus was conceived the idea of one man, with assistance, delivering a fire greater in volume that he alone could otherwise have attained with his individual weapon, and the economizing of man power.

When, towards the latter half of the 15th century, the field artillery improved, and a cannon ball could be fired from a gun mounted on a mobile carriage, these *ribaudequins* gradually dropped out and eventually ceased to exist.

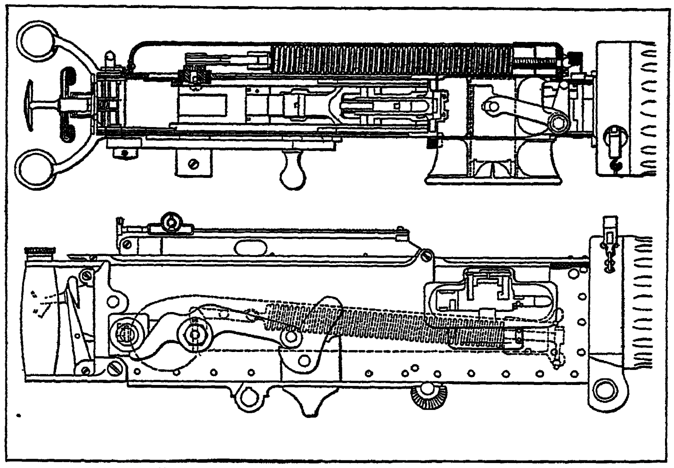
Soon after this, however, the same idea was re-employed in a more up-to-date form, known as *orgues*, or organ guns. In these, a number of musket barrels were mounted side by side in a frame on a wheeled carriage, the latter having also a number of pikes projecting to the front, and intended for the ultimate protection of the personnel against frontal attack or cavalry charges. These barrels were so arranged that they could be fired singly, by means of locks, or alternatively by a single lock, which ignited a quick match which in turn ignited the charges of all the barrels in rapid succession. However, with the further development of the artillery it was realized that these "organs" had the fatal defect of being neither powerful enough to engage, nor mobile enough to evade the hostile artillery. (An interesting resurrection of this old idea was employed in the World War when rifles were mounted in frames, laid to sweep approaches and trenches, and operated by one man.)

The usual competition to improve and outdo the armaments then employed began shortly afterwards, and inventions were numerous, if often impractical. An instance of the development that took place is embodied in a weapon still to be seen in the Tower of London, which would appear to have been made before the advent of the flint-lock in the first half of the 16th century. It is an arquebus of the period, with four chambers and a single barrel, a separate flash pan for each chamber, with the chambers revolving round a central axis.

In 1701 we find a wider view taken of the rôle that such a weapon should fulfil, when Beaufort de Mirecourt, a Lorrainer, laid down that such a weapon should have as its purpose the augmentation of infantry fire power, so as to place a numerically inferior army on an equality with one superior to it in numbers, etc. Then, in 1718, we find a patent granted to one Puckle, to produce a gun, which had one barrel but had also a revolving cylinder in which were seven or nine chambers. The equipment also consisted of moulds for making the necessary balls. It seems probable that there were two cylinders, for in his application for the patent he proposes "round balls for Christians, square balls for Turks." A very important development in all forms of fire-arms was made when in 1805 Alexander Forsyth invented the percussion system of igniting the charge.

This principle is to be seen embodied in another interesting old weapon which has been in the custody of the war department since 1830, and is at present housed in the Rotunda at Woolwich. When it was first made cannot now be ascertained. In it are three rows of barrels, 11 in the middle row and ten in each of the others. All are fixed, and the alignment and elevation are practically the same for all. The barrels are over 44 in. long, ·75 in. bore, with 11 grooves, twisting one turn in 30 inches. In rear of the barrel and clamped thereto is a plate on which are mounted chambers for each of the barrels. In rear of these chambers was a combustion box, with which each chamber was connected. This was charged with powder. A percussion cap, mounted on a nipple, when struck by a large hammer under the influence of gravity, ignited the powder in the combustion box and so ignited the powder in the barrel chambers, thus firing all 31 charges simultaneously. An accessory is a machine for loading and charging the plate of chambers. During the early half of the 18th century similar weapons were used in France.

In the same museum is a rifle battery, designed by Sir J. S. Lille, and made in 1854. It consists of two rows of six barrels one above the other and some 6 in. apart in each row. In rear of the barrels are cylinders, similar to the cylinders of the modern revolver. The cylinders in the top row contain ten chambers, and in those of the bottom there were twenty. Each chamber is provided with a nipple for a percussion cap. In rear of these cylinders were rods, on which were mounted hammers for each barrel. On rotating these rods by means of crank handles, the cylinders were caused to revolve, and the hammers fell in succession, starting from the right. This weapon was designed at the time of the Crimean War, but it is not known if it was ever employed in the field. From the foregoing it can be seen that a stage had been reached when a limited number of rounds, fired in rapid succession or as a volley, could be easily arranged, but the problem of rapidly reloading the discharged barrel was ever present, and so precluded the possibility of continuous fire. This great limitation to the utility of these weapons lasted until a system of loading them at the breech instead of the muzzle was introduced. Meanwhile, consequent on Forsyth's invention of the percussion cap in 1805, developments in ammunition had taken place. Gustavus Adolphus of Sweden in the 17th century had caused the gunpowder, which had hitherto been carried in flasks or bandoliers, to be made up into cartridges, which soon developed into the complete cartridge with bullet, charge and percussion cap all in one and contained in a paper case. Such cartridges, rough as they were, lent themselves to employment with breech-loading mechanisms, and in 1838 Dreyse embodied such a system in the Dreyse needle gun.



BY PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE

FIG. 1.—THE .303" VICKERS MACHINE GUN

The Gatling Gun.—Twenty years after this came the first practical machine gun, invented by Gatling of Chicago. In this gun, a number of barrels (usually ten) were arranged round a central axis, and behind each barrel was a bolt, complete with firing pin and spring and extractor. The cartridges were carried in a hopper or slide above the gun, and fell by their own weight in front of the open breech of each barrel as it came round. By turning a crank handle at the side of the gun, barrels and bolts were revolved, each barrel being fired in succession when it arrived at a certain point in its circuit. Starting from that point, during the first semicircle the bolts were fully withdrawn and the cartridge case extracted; during the remainder of the circuit, the bolts closed the breech and fired the rounds.

This gun was employed in the American Civil War and later the ·45 Gatling was adopted by the British navy. With it a rate of fire of about 600 rounds per minute could be obtained. Its accuracy, however, could not have been of a high order as it is on record that at Gibraltar, 18 men selected from an infantry regiment, and armed with the single-loading Martini-Henry rifle, were able to make a better score on targets in a given time than a Gatling gun skilfully handled by 18 blue-jackets. An improved system (Accles) of feeding the gun was later invented, which made possible a rate of fire of 107 rounds in $2\frac{1}{2}$ sec. This improved system was produced too late for it to be adopted in the British service, which by that time was committed to other designs.

In Europe, the first machine gun to attract general attention was the Montigny Mitrailleuse, introduced into the French army just prior to the war of 1870. The French, disappointed with their shrapnel in the Italian War of 1859, desired a weapon, the projectiles from which would carry to ranges which the infantry, and the artillery firing case shot, could not reach. These guns were attached to batteries of artillery, and in their final form resembled outwardly an ordinary field gun with a wheeled carriage, limber and four-horse team. This mitrailleuse consisted of 37 rifle barrels, fitted in an outer casing, the whole revolving round

a common axis. The cartridges were carried in perforated plates To load the gun these plates were placed in grooves and locked in the breech, which was then forced home, each cartridge entering one of the chambers. The gun was fitted with a crank handle, which, when turned, revolved the barrels and fired each of the cartridges in succession, all 37 being discharged in one revolution.

Though tactically often badly employed in the field, and consequently put out of action by the German artillery, this gun proved that means could be provided which would enable a few men to pour a continuous stream of bullets on any spot, and thus be a factor in war too important to be overlooked. This gave a new impetus to inventors, and other guns were soon produced; the best known being those of Gardner, and Palmcratz and Nordenfelt. In the British Service, the Gardner superseded the Gatling. Guns of this description were made with one, two or five fixed barrels and could fire about 120 rounds per minute, provided that no troubles arose in the gravity fed supply of ammunition.

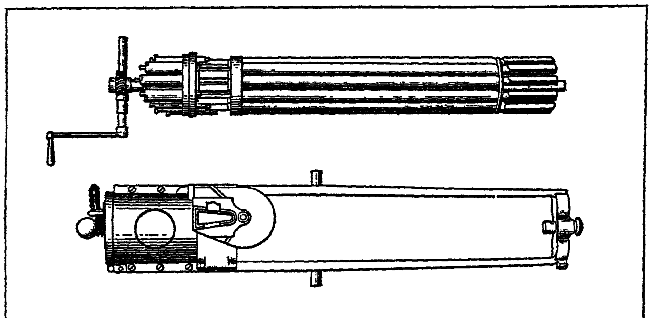


FIG. 2.—LIGHT GATLING GUN (.300 IN.) USED AT SANTIAGO, 1898

When later the Palmcratz-Nordenfelt rifle calibre machine was perfected, it was submitted to trial and proved to be the most reliable quick-firing gun yet produced, and eventually it became the machine gun, not only of the British service, but also of the services of most of the leading Powers. Like the Gardner, this gun also had two or five barrels fixed side by side, and was actuated by a lever worked backwards or forwards. The mechanism was simple and strong, and its maximum rate of fire a little over 600 rounds per minute. The cartridges were contained in a magazine situated above the breech action, from which they fell by gravity into position in front of whichever breech was open, and were subsequently fired through the action of the lever closing the breech.

The Maxim Gun.—Then in 1889 came the great development made by Sir Hiram Maxim. In all the guns hitherto produced, functioning was obtained by the hand operating a crank or lever. In the Maxim functioning was truly automatic, the recoil of the one barrel employed being utilized to perform all the operations necessary for loading, firing and ejecting. In this way the firer was spared the exertion hitherto expended on cranks and levers, which latter also had a tendency to cause unsteadiness of the gun, and loss of alignment. There were several new features in this gun which were true inventions. The rows of barrels, hitherto exposed to the air in other guns, were reduced to one single barrel which, for the greater part of its length, was enveloped by water in a casing. The method of feeding the gun with ammunition was also new, namely, a fabric belt holding 250 rounds in lieu of the older gravity feeding magazines, etc. The locking of the action against the force of the discharge was a further new and most ingenious feature.

The first gun that was made performed perfectly and fired at a rate of between 600–700 rounds a minute. So struck was the well-known Chinese envoy Li Hung Chang when witnessing a demonstration of this gun consuming ammunition at this rate, that he remarked "That won't do for China, it's much too expensive in ammunition." This gun was adopted by Germany and Russia and was their principal machine gun in the World War. In the British army it was adopted in 1889 and in the navy in 1892. In the hands of the latter it was employed in many fights, and it was the only small calibre machine gun used in the Boer War. At the outbreak of the World War it had been superseded in the British cavalry by its lighter offspring, the Vickers (which is referred to later) but the change over had not extended to the infantry when the war began. In the British services it is now obsolete, its place being taken on land, on the sea and in the air by the Vickers ·303.

Light Machine Guns.—When in the World War trench warfare set in and the power of manoeuvre disappeared, it was no longer possible to establish a superiority of fire by skilful tactics. Hence arose a greater demand for automatic weapons to increase the volume of fire, should occasion demand, and also to economize in riflemen. In the battles fought in the early days of trench warfare, the muddy state of the ground, the obstacles to be surmounted, and the heavy weight of the existing machine gun and its mounting frequently prevented the gun teams from getting the gun forward into the positions ordered. For such a task, lightness and mobility were even more important than accuracy and capacity for sustained fire. Hence the demand arose for a light machine gun, which thus took its place in the equipment of the modern army. Several different kinds were employed and are referred to later.

THE MODERN MILITARY RIFLE

The modern rifle is so constructed as to constitute a complete offensive and defensive arm for one man, of such a size and weight that one man can carry it, together with its ammunition and accessories and the other essentials that a soldier is required to carry over the ground and for the distances he is expected to cover in war. The weight of the military rifles of most countries averages about 9 lb. without the bayonet which weighs about 14 oz. All modern military rifles are breech-loaders with "bolt" systems and have magazines carrying 5–10 rounds. In all cases, except in the rifles of Greece and Russia, the double pull trigger system is employed. In this system, the mechanism is so arranged that, after a long light pull of the trigger, a greater resistance is suddenly felt. From this point on a heavier pull is required until the firing pin is released and flies forward to fire the round. The light pull is called the "first," and the other the "second" pull.

Usually the barrels taper towards the muzzle, either evenly or in steps, these latter being thought to break up or damp down the vibrations of the barrel caused by the explosion and which affect the accuracy of the shooting. In length the barrels run from about 24–32 in., the bores vary between ·256 and ·315 in. and the weights between 2 lb. 3 oz. and 3 lb. 3 oz.

The function of the bolt is to support the cartridge in the chamber during the explosion and so seal the bore against the escape of gas. On the right of the bolt, and usually towards the rear end is the bolt lever for its manipulation. The bolt is of steel, hollowed out to contain a firing pin and a spring (mainspring), with which to fire the round. Mounted on the bolt and projecting beyond it is the extractor, which grips either the rim or cannelure at the base of the cartridge, when the bolt is fully forward.

When the bolt is drawn to the rear, the cartridge case is removed from the chamber and its ejection from the rifle takes place during this backward movement. When the bolt is fully back, a round is pushed by a spring from the magazine and so held that when the bolt is again pushed forward, it drives this round in front of it into the chamber. During this forward motion of the bolt, the firing pin within it, coming in contact with a sear which is operated by the trigger, is arrested. The bolt continues to go forward, compressing the mainspring which actuates the firing pin. The firing pin is then in the cocked position, and if the trigger be pulled the sear will disengage from the firing pin and the latter will fly forward to fire the round. Bolts are always designed with locking devices, so that when the bolt is fully forward it is firmly held to the breech, supporting the cartridge and sealing the bore against the pressure of gas. These locking devices must be strong, as the gas pressure generated by the explosion in modern military rifles may reach as high as 20 tons to the square inch. In short, it may be said that the heart of the whole rifle lies in the bolt and its components. Though breech actions are all of the bolt principle, there are, nevertheless, wide

and varied differences in such bolts. There are two main bolt systems namely "rotating" bolts, and "straight pull" bolts. Of these, the former are most common. Rotating bolts are those which, before they can be unlocked and drawn to the rear, must be rotated.

Primary Extraction.—On the explosion of the charge the cartridge case expands and grips the walls of the chamber, thus helping to seal the bore. When the pressure drops, the case should contract, but it may not do so sufficiently to ensure its easy extraction from the chamber. A rotating action has the advantage that, by means of sloping surfaces, a very powerful leverage can be exerted on turning the bolt by its lever, thus loosening the cartridge case in the chamber, before pulling the bolt to the rear. This loosening operation is called "primary extraction." Straight pull bolts can perhaps be operated a trifle more quickly without removing the rifle from the shoulder, but withdrawal of the bolt may be difficult, as there is no primary extraction.

Bolt Locking.—The locking devices most commonly employed take the form of studs, or lugs on the bolt, which when the latter is turned enter recesses in the body of the rifle, *i.e.*, the part into which the barrel screws and within which the bolt moves. These locking lugs on the bolt may thus be situated (*a*) towards the front or (*b*) towards the rear of the bolt and (*c*) variously situated. Theoretically, rear locking rifles are inferior to front locking, as the whole length of the bolt, back to the rear face of the lugs, is under compression, and fracture is more probable over this length. Moreover, the recesses for the lugs are towards the rear of the body; thus under the force of each explosion there is a tendency for the bolt to compress and the body to elongate, which may in time cause imperfect support of the cartridge in the chamber.

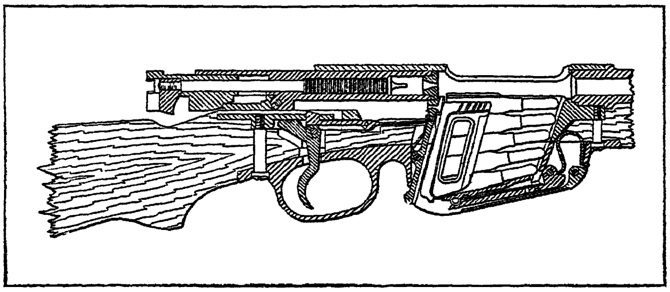
The British Lee-Enfield rifle has a rear locking bolt, but, though rear locking is weak in theory, this action did most satisfactorily all that was asked of it in the severest test that any rifle has had to undergo, namely the World War.

Furthermore, it was claimed for this rifle that the ease with which the bolt can be manipulated enables a higher rate of aimed fire to be delivered from it than from any other hand operated, bolt action rifle. Due to this rapidity of fire the Germans, in the first encounters of the war, attributed to the British Army many more machine guns than in fact they possessed.

The Swiss Schmidt-Rubin is a rifle with a rear locking bolt. The Krag-Jorgensen rifles of Norway and Denmark are types of (*c*), having one lug in front and another in rear and at a right angle to it. The large majority of military rifles are, however, locked in front, some, *e.g.*, U.S.A., having a third lug in rear. Some bolts are made in one piece throughout their length, others have a detachable bolt-head and are known as two-piece bolts. The merit of the two-piece bolt is that, should the bolt contract under the successive explosions of ordinary usage, a cheap and effective repair can be made by fitting a new bolt-head and so obviate condemning the whole bolt.

Sights.—The sights of military rifles should be strong, simple and easily legible; quickly adjustable, and not liable to movement due to the jar of recoil. They should also be sufficiently far from the eye and from each other to allow of quick and accurate aim being taken. The foresights are usually either a vertical "blade" or triangular "barleycorn." The backsights for alignment with these foresights are notches of either "U" or "V" shape respectively, or a circular aperture, which may be mounted on either vertical tangent or ramped radial sights.

Loading and Magazines.—Most nations now carry their ammunition in chargers or clips, which usually hold five rounds. When a charger is used, it is placed in guides on top of the body, thus permitting all five rounds to be pushed into the magazine in one movement, the bolt being first brought to its rearmost position. The charger is then removed, and, in action, thrown away. When a clip is used it is placed complete with its rounds in the magazine, at the bottom of which is a spring pushing the rounds upwards. When the last round has been taken from it, the clip falls out by its own weight through a hole in the bottom of the magazine. This hole is liable to permit of the entry of mud or dirt into the metal mechanism, however. The most common magazines in army use take the form of a vertical box underneath the bolt when in the forward position. A platform, mounted on a spring, keeps an upward pressure on the column of cartridges ensuring that the top round is always in position for the bolt to drive it forward into the chamber. The French Lebel rifle is now



"TEXT-BOOK OF SMALL ARMS," BY PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE

FIG. 3.—MANNLICHER RIFLE, AUSTRIAN

so fitted, but not until 1915 was it converted, prior to which the rounds were held in a tube underneath the barrel, and were pushed to the rear by a spring plunger.

The box magazine in a different form is employed in the Krag-Jorgensen rifle of Norway and also in the Mannlicher-Schoenauer of Greece. In the Krag-Jorgensen the box is on the right and the rounds are pressed by a spring lever underneath the bolt and come round and up into position towards the left of the bolt face when it is withdrawn. In the Greek rifle the magazine platform rotates round an axis and against a spring. The rounds are loaded from the top, the platform yielding to the pressure of the loader's hand. When the bolt is to the rear this platform is caused by the spring to rotate in the opposite direction so feeding the rounds.

All rifles except those of France and Denmark are provided with a safety catch or bolt. This, when applied, prevents the firing pin from going forward if the trigger be pulled. Also, in most, its application prevents the bolt from being turned.

Types of Rifles.—Subject to minor variations, the military rifles of the principal nations are of the following distinctive types: Short Lee-Enfield (British), Mauser (German) Mannlicher (Austrian) *see* fig. 3, Lebel (French), Krag-Jorgensen (Norwegian and Danish), Schmidt-Rubin (Swiss) and Nagant Three Line (Russian). Including the United States of America the Mauser type is possessed by 22 different States. Details of the rifles of various different nations are given in the table on p. 808. All of the rifles shown in the table on p. 808 have rotating bolts with two exceptions, namely, the Austrian Mannlicher 1895 pattern and the Swiss Schmidt-Rubin.

SPORTING RIFLES

Modern sporting rifles using smokeless cordite, nitro-glycerine or nitro-cellulose powders are various and differ according to the requirements they are wanted to fulfil. Dangerous and non-dangerous game call for different requirements and the former can be subdivided into thick-skinned animals, such as elephant, rhinoceros, buffalo and bison; and thin-skinned, such as lion, tiger and leopard. For dangerous game a heavy bullet of big diameter with sufficient velocity to give a paralyzing blow is essential, but in addition high penetrative power is also required when engaging thick-skinned beasts.

Modern sporting rifles run from ·600 in. down to ·240 in. in bore and their ammunition also varies in weight and velocity of bullet, as well as its capacity to penetrate or expand on impact.

In the United States many sporting rifles of medium caliber and velocity are manufactured with tubular magazines under the barrel, and a breech action operated either by means of a finger lever or a sliding forearm. Such rifles will handle cartridges of medium breech pressure, suitable for American game, very effectively, but are not satisfactory for heavier cartridges necessary for the larger game of other continents, nor do they usually

quite equal in accuracy the magazine rifles built on military bolt actions.

Such rifles usually take the form of either single barrel, double barrel or single barrel magazine weapons, the latter usually being on the lines of one of the well-known types such as Lee-Enfield, Mauser, Mannlicher and Ross.

Miniature rifles are used for instructional and competitive target shooting at short ranges and also for small game shooting, etc. The most usual bore is ·22 in., taking a rim-fire cartridge. Care should be exercised when using these in the field in closely cultivated countries, as this little bullet is capable of an extreme range of 1,250 yards.

Miniature rifle shooting has now become a favorite sport in Great Britain and the United States. It can be carried on almost anywhere as quite safe ranges can be built in or close to the larger cities. Firing is done up to 200 yards. In the United States a ·22 calibre miniature rifle similar to the Model 1903 military rifle has been issued to all troops, and has been found to be a very great aid and economy in target practice.

AUTOMATIC RIFLES

The term "automatic" when applied to a weapon implies the continuance of fire without cessation, on the trigger being pressed. "Semi-automatic" implies the firing of not more than one round for each pull of the trigger. Accordingly, the former may be described as a self-firer, and the latter a self-loader. In both cases the operations of extracting and ejecting the fired round and reloading the next one are derived from the power of the explosion. For military purposes, the self-loader is the more suitable, as with the self-firer a great deal more ammunition will often be expended than the circumstances require and there will be difficulty in keeping the firer supplied with ammunition. An automatic or semi-automatic rifle, to be carried by the soldier and handled like an ordinary military rifle, should not exceed about 10 lb. in weight.

The vibration and recoil of such a light weapon, during a "burst" of continuous fire, is such that it is impossible to hold the rifle so that the aim is maintained throughout. Thus, in practice, the first shot of the burst is the only one fired while the rifle is aimed on the mark, the rest being uselessly expended. In these circumstances the self-firer has no advantage over the self-loader and is more wasteful in ammunition. From the foregoing reasons it can be seen that though the term automatic rifle is used, the semi-automatic or self-loading rifle is the one usually intended. For such a rifle to rank as a complete offensive and defensive weapon, as does the military rifle, it must take the same ammunition and give the same ballistic results. Also it should lend itself to effective use in close combat when fitted with a bayonet.

Though a great deal of work has been devoted over a number of years and in various countries to endeavouring to produce a really reliable weapon, no army has yet adopted this form of fire-arm, although Germany in the World War, made and used a certain number of the Mondragon rifle, which originated in Mexico. With all the experience now available, and the continuance of experimental work and development, a really satisfactory weapon may perhaps become an accomplished fact. The problem, however, is one of great difficulty because, while such a rifle has necessarily to be almost of the same weight as the military rifle, it has to comprise, in addition to the parts present in that rifle, the extra parts required for the automatic operations, and these, to be durable, must add appreciably to the weight. In the past, gas and recoil operating systems have been tried, and also special ammunition, but although inventions have been numerous no rifle of this nature has been found sufficiently free from defect to warrant its adoption.

LIGHT MACHINE GUNS

A light machine gun is a truly automatic (self-firing) fire-arm which is portable but which is too heavy to be adapted for use as a close-combat weapon. The increased weight (17–28 lb.) makes the recoil energy less than that of the rifle, and as a rest is provided at the front end the continuous fire delivered remains reasonably accurate under ordinary conditions. To make the best use of this weapon much ammunition must be carried and it is accordingly manned by a team, one man carrying the gun and the others ammunition, spares and accessories.

Light Machine Guns in the World War.—Though the quest for the automatic rifle had started some years before the World War, up to 1914 the main armament of infantry in all armies was the rifle (with bayonet), and the machine gun averaging 40–50 lb. in weight, on a fixed mounting. The requirements which were encountered in the World War and which led to the introduction of the light machine gun are given above.

All these weapons are operated either by the gas or by the recoil generated by the charge, and all are now air cooled. All gas-operated weapons are practically identical in principle and where differences occur they are usually only in matters of detail. Usually, the gas is diverted through a hole in the barrel into a cylinder, where it strikes the head of a piston and drives it to the rear. Towards the rear of the piston are embodied devices which connect it to the "feeding" arrangements and also to those for sealing the breech and firing the round. The piston, when driven to the rear, compresses a spring which, having absorbed the thrust, returns it to its forward position. As the piston travels to the rear the following operations are performed—extraction and ejection of the fired round, and the presentation of the new round ready for insertion into the chamber. When the spring forces the piston forward, the bolt (mounted on the piston) drives the round into the chamber. During this movement, locking devices come into play and lock the bolt to the breech, thus sealing it and supporting the bolt against the explosion. This occurs before the finish of the piston's travel, so that the striker, carried on the piston, only strikes the cartridge cap after locking has taken place, and the weapon is accordingly "mechanically safe." Unlocking takes places after the piston has been driven a short distance to the rear, by which time the bullet is out of the barrel. In this respect also the weapon is "mechanically safe." A typical gas-operated light machine gun is the Lewis (*see* fig. 4) or Browning.

In recoil operated light machine guns, the mechanical systems employed are more varied than are those used in gas-operated

weapons, and there is no general principle to which they closely adhere. A feature common to all, however, is the recoiling barrel which overcomes the resistance of antagonistic springs. These, at the finish of its backward travel, return the barrel to its forward position. The length of recoil varies in different guns from about 1 in. to 5 in.; consequently they are classified as "long" or "short" recoil. (The length of the recoil is shown in the table below.) Another common feature is that the barrel and bolt (or lock) are mechanically locked together for a certain length of the recoil, thereby sealing the breech until the bullet is clear of the barrel. In "long recoil" actions, the bolt, having come back with the barrel, is held in its rearmost position, with the extractor engaged behind the rim of the cartridge which is still in the chamber. Accordingly, as the barrel moves forward under the influence of the springs which have been overcome in the backward travel, the round is withdrawn from the breech and ejected. The Chauchat, now obsolescent in the French army but adopted in that of Belgium, is a type of the "long recoil" gun.

In "short recoil" actions, such as that of the Bergmann gun of approximately one inch barrel movement, a form of mechanism is provided whereby the bolt, locked to the barrel for a certain length of recoil (created by firing) is unlocked and withdrawn about 3 in. from the barrel after the latter has completed its inch of recoil. In this separation of bolt and barrel, extraction and ejection of the empty case is effected, and a new round is inserted into the chamber. The Madsen action does not conform to the above description, as in this case the separation of breech from bolt is effected on recoil by guiding the bolt away from the barrel in a vertical plane, the bolt being pivoted in rear to permit this movement.

In "short recoil" guns, the recoil and the return of the barrel is the source of power for operating the mechanism which brings about the feeding of the cartridges into the gun, in the same way as does the piston in gas-operated weapons. Normally, with such guns the rounds are contained in a belt which is mechanically led through the gun, the rounds being withdrawn from it during its passage. In "long recoil" weapons, the system of feed is usually by magazine, the rounds being pushed by a spring inside the magazine into the space which is created when the bolt remains back as the barrel goes forward.

The Sub-machine Gun.—The sub-machine gun is a kind of automatic pistol, but heavier, more powerful, and with a longer range than the usual pattern of pistol. It is capable of a high rate of fire and is lighter than other automatics. The ammunition is similar to pistol ammunition. In the Thompson sub-machine gun the breech is sealed by the agency of inertia together with the adherence of inclined surfaces to those portions of the mechanism which support the bolt against the gas pressures generated within the barrel.

Some of the principal light machine guns employed during the World War and some of the newer types are tabulated below with a few details.

Locking Actions.—As the locking action is perhaps the most important part of the mechanism of any automatic weapon, a short description is given of the well-known method employed in the Vickers gun and also the unusual methods employed in the Schwarzlose (*see* fig. 6) and Revelli guns.

The Vickers.—The lock is connected to a crank by (1) a side lever head, whose axis we shall call *a*, and (2) a connecting rod, whose axis we shall call *b*. The axis of the crank we shall call *c*. In the locked position, axis *b* is slightly below axis *a* and *c*, and the crank, under *b*, bears on the crank stops. The rearward thrust of the cartridge on explosion thus passes through *a*, *b* and *c*. As *b* is lower than *a* and *c*, it cannot under pressure rise above the line *ac* and so unlock the action. It must tend downwards. However, the crank is already bearing on the crank stops under *b*,

¶Belts for aircraft are of metal disintegrating links.

hence no movement here is possible and so the locking action is effected.

Except that the crank revolves downwards instead of upwards, the system of locking in the Maxim gun is practically identical with that employed in the Vickers.

Inertia Sealing of the Breech in the Schwarzlose.—There is no positive locking in the gun, reliance being placed in heavy moving parts and a strong spring, to induce sufficient inertia to seal the breech. With a view to ensuring the exit of the bullet from the barrel before the inertia is overcome, the barrel is abnormally short.

The mechanism includes a massive, heavy breech block *a*, connected by a crank link to the upper axis of a crank. The lower axis of the crank works in bearings in the body-casing of the gun and has no backward or forward movement. In rear is a strong spring pushing the bolt forward. The thrust on the face of the breech block pulls the crank link to the rear. It, in turn, pulls the crank to the rear.

However, owing to the set of the crank in relation to the lower non-recoiling axis, much resistance to the rearward motion of the breech block is set up. Thus it is that, coupled with the heavy resistance offered by the strong antagonistic spring and the weight of the moving parts, sufficient inertia is created to prevent the breech from opening prematurely.

The Revelli.—On explosion, a barrel with a sleeve *a* recoils, and the gases, acting through the cartridge head, impart a rearward movement to a breech block *b*. At this stage, the breech block and sleeve are held together by a claw, on a rotating wedge. The rearward movement of the Revelli breech block causes the wedge to rotate to the rear. In so doing, the claw, which passes through a slot in the sleeve, bears against the latter at the shoulder, and helps to force the sleeve and barrel rearward. After *a* and *b* have moved about 4 mm., the claw is entirely disengaged from the breech block, which continues to the rear under its own momentum. The wedge in rotating compresses a strong spring, so the tip of the claw bears against the under side of the breech block, and is prevented from regaining its forward position. Hence the sleeve cannot do so until the recess in the breech block returns to within 4 mm. of its forward position.

MODERN MACHINE GUNS

The machine gun is an automatic small-arm weapon, usually provided with a fixed mounting and capable of sustained accurate fire. A heavy machine gun does not differ materially from an ordinary machine gun in design, but as its calibre may be from 0·5 to 0·9 in., it is necessarily of a heavier and stronger make. The weight of a machine gun, however, if in the hands of infantry or cavalry, is limited by the consideration that, by whatever means it may be transported, it must in the last resort be "man-handled" into position often over considerable distances and under difficult conditions. On the other hand, lightness and portability are desirable only in so far as they are consistent with strength, for to a large extent it is on the strength and, therefore, weight of the mechanism that the ability of a gun to sustain fire depends.

Mounting.—The fixed mounting with which the machine gun is provided increases the accuracy of all ordinary shooting, and thus enables the gun to be used either for indirect fire or for fire over the heads of friendly troops, when supporting an attack or covering a retirement. To support rigidly a machine gun weighing from 40 to 50 lb., the mounting must be strong and fairly heavy, otherwise the combination will be top heavy and unsteady, and the shooting in consequence will be inaccurate. The mounting must permit of the gun being traversed through as wide an arc as possible, and also permit alterations to be made in elevation.

Machine guns for ground use normally have a rate of fire of about 450–500 rounds per minute, but, owing to the necessary replenishment of empty belts or magazines, etc., the number of rounds actually fired per minute is much less. In aircraft a higher rate of fire is desirable and is usually obtained.

Cooling Systems.—For sustained fire an efficient cooling system for the barrel is essential. The higher the temperature of the barrel, the less its resistance to wear. There are two systems in use, namely, radiation in air and water-cooling. Heavy barrels with radiating rings are sometimes employed for ground use (*e.g.*, the French Hotchkiss). The water-cooling system is the most common. The barrel for nearly the whole of its length, is surrounded by water contained in a casing which, with recoiling barrels, is fitted with glands to prevent leakage. Inasmuch as prolonged rapid fire causes the water to boil, a steam escape is

necessary. Accordingly a flexible tube is usually attached to the steam escape whereby the steam is led to a portable condensing chamber, and converted back into water for use again in the gun. The water increases the weight of the gun by about 9 lb., and for this reason light machine guns rely on radiation for their cooling.

Mechanical Safety.—All automatic weapons are required to be "mechanically safe," that is, the design must be such that the gun cannot be fired unless the action is fully closed and the cartridge properly supported. Even then, it should only be able to fire by means of the trigger mechanism, which itself must be proof against heavy jarring. Safety catch ("applied safety") devices should operate directly on the firing pin or striker, and should preclude the possibility of this ever being able to reach the cartridge by accident.

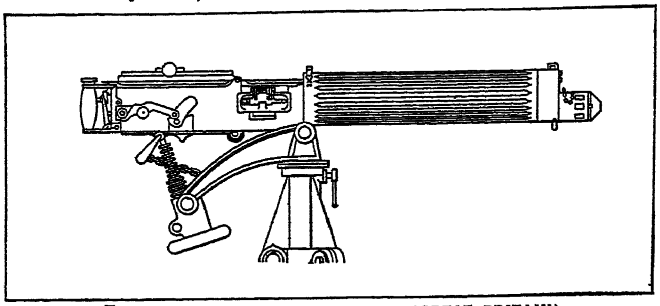

FIG. 5.—VICKERS MACHINE GUN (GREAT BRITAIN)

For the automatic operation of machine guns power may be obtained in three distinct ways, viz., from the gases generated by the explosion of the charge, from the recoil of the barrel, and from the backward thrust of the cartridge on explosion. In some types of gun two of these principles of operation are combined. The French Hotchkiss gun is gas operated, on principles which have been explained in connection with light machine guns.

Barrel Recoil Only.—In the U.S.A. Browning water-cooled gun, when a round is fired, the barrel, barrel extension, and breech-block move backwards locked together for $\frac{5}{8}$ inch. A locking block is forced down clear of the breech-block, and the latter travelling further to the rear compresses the mainspring. A lever working in a slot on the breech-block operates a slide, which, by means of pawls, feeds the belt of cartridges into the gun. On the breech-block is carried the extractor which takes a round from the belt as the breech-block goes backwards, and places it in guides on the front of the block. When the breech-block is driven forward by the mainspring, the lever and slide move to grip a new round, and the round already in position is placed in the chamber. The trigger action inside the breech-block is cocked during the backward movement. This action is so designed that the trigger is unable to operate the sear unless the breech-block is fully forward and therefore locked. The gun is thus mechanically safe.

Recoil and Gas.—In the Vickers gun (*see* fig. 5) gas is trapped at the muzzle and rebounds on to a muzzled cup screwed to the barrel, thus augmenting the recoil. For about $\frac{1}{2}$ in. of recoil the barrel and lock are held together in the locked position. By this time the bullet is clear of the barrel and the unlocking begins. Attached to trunnions on the barrel are side-plates which move with it. Over the breech is the feed block into which the cartridge belt is fed by a slide similar to that used in the Browning, but operated by a lever in the left side-plate. Further to the rear and between the side-plates is the crank with the connecting rod to which the lock is attached. The crank is prolonged outside to the right of the gun and on it is mounted a crank-handle. This latter is so shaped that on coming into contact with a "roller" during the recoil it is rotated upwards and to the rear. This causes similar movement of the crank and by this means the lock is withdrawn from the breech. A strong spring on the left of the gun called a fuzee spring is put into tension by the rotating of a fuzee to which the spring is attached at the left hand of the crank. The barrel and side-plates are returned to their forward position by a secondary movement due to the crank-handle and roller, but the lock is brought forward by the rotating action given to the crank by the fuzee spring. On the face of the lock is the extractor. When the lock goes to the rear the extractor drops, but rises again to its full height when the lock is fully forward. During rapid fire when the extractor is up it is gripping a live round in the feed-block, and supporting the round in the chamber. When the lock travels to the rear the extractor drops, and the spent round is extracted and ejected through the bottom of the gun, and the live round is brought to the same level as the chamber. As the lock goes forward the live round is placed in the chamber and the extractor completes the cycle by rising again to grip another live round in the feed-block. The firing pin and spring, sear and trigger, etc., are contained within the lock. A firing lever operates the trigger and so long as this firing lever is pressed, this cycle of operations will continue as described.

Cartridge Projection.—The Austrian Schwarzlose (*see* fig. 6) is inertia operated, *i.e.*, the backward thrust of the cartridge drives to the rear a heavy breech-block against a strong spring, which in turn pushes it forward. To ensure against the cartridge gripping the chamber too tightly and so having insufficient thrust, provision is made to oil each cartridge before its insertion into the chamber. The cartridge belt is led from the right on a toothed wheel situated below and in the rear of the barrel. This wheel is rotated by the movements of the breech-block. A claw at the bottom of the breech-block draws a cartridge from the belt on to the rotating wheel and this places the round in front of the breech-block to be driven forward into the chamber. A heavy firing pin passes through the breech-block and is pressed forward by the mainspring. An arm is connected to the firing pin and it has on it a bent or step which engages on a similar bent on the breech-block when the firing pin is cocked. A trigger bar when drawn to the rear by a thumb piece at the end of the gun raises this arm and when the bents are disengaged the firing pin flies forward to fire the round. Ejection is to the left and is effected by a plunger on the right side of the breech-block.

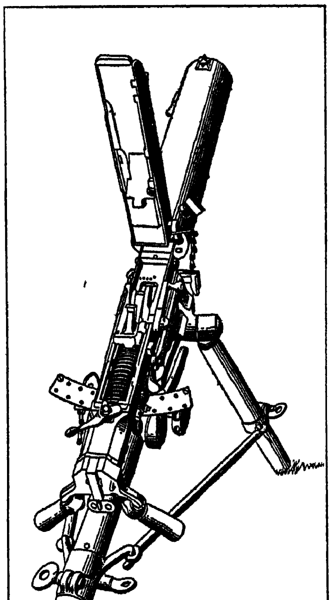

FIG. 6.—SCHWARZLOSE MACHINE GUN (AUSTRIA)

Recoil and Cartridge Projection.—The Italian Revelli uses a combination of barrel recoil and cartridge projection. A sleeve is attached at the rear of the barrel. Inside this sleeve lies the breech-block and inside the latter is the firing pin and mainspring. This spring drives the breech-block and the firing pin forward. On firing, barrel, sleeve and breech-block move together to the rear a distance of 4 mm., after which the breech-block goes on free for about 6 in., compressing the mainspring. The locked motion of these principal components is explained above under "Locking Actions." A sear which engages with the firing pin is operated by a thumb piece plunger at the rear of the gun, which, when pressed, disengages the sear and firing pin. A secondary sear is also provided which prevents the gun from being fired if the moving parts are not fully forward and the gun is thus mechanically safe.

This is the only well-known water-cooled machine gun which is not belt fed. The cartridges are contained in a magazine holding 50 rounds, there being ten compartments, each with platform and spring. The breech-block on going forward takes the top round from the first compartment and when this is emptied the magazine is caused to move to the right so bringing the next compartment into action and so on until the fiftieth round is fired, when

the magazine is knocked clear of the gun. A secondary mechanical safety device consists of a small plunger protruding into the inside of the breech-block. The firing pin on going forward meets this and drives it out and towards the left. A recess is made in the body casing so positioned as to take this plunger when the breech-block is fully forward. If the latter is not fully forward,

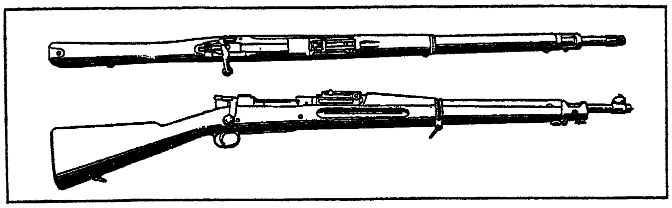

FIG. 7.—SIDE AND TOP VIEWS OF U.S. 30 CALIBRE RIFLE

the plunger cannot move into the recess and its tail prevents the firing pin from protruding.

FUTURE DEVELOPMENTS

From the soldier's or hunter's point of view there exist certain features of small arms and their ammunition upon which it would be desirable to improve. To both the requirement of seeing without being seen is ever present. The flash of the explosion is, however, unmistakable, especially at night, and at once discloses the presence and the position of the firer. Possibly in the future a special powder or other means will be devised which will reduce or even eliminate the flash of the discharge. Such powders have been produced in the United States, Silence, too, especially if coupled with a flashless discharge, would increase the probability of the firer remaining undetected. In the past, attempts have been made to reduce the noise of the explosion by means of a silencer, but apparently they have not met with such success as to have merited adoption.

Metallic Fouling.—"Metallic fouling" in the barrel is another and ever-present trouble. It is produced by the bullet envelopes, usually composed of an alloy of copper and nickel, which, when travelling at a high velocity, are prone to leave behind small particles of the envelope adhering to the bore, thus spoiling its true cylindrical form and so causing inaccuracy in the shooting. Metallic fouling when steel envelopes are used, is practically negligible, but a difficulty with these which has not as yet been generally overcome is to manufacture a steel or other substance which, while being tough enough not to leave particles in the bore or to erode it unduly, will yet be soft enough to permit of its expanding sufficiently to "bottom" in the grooves of the rifling, and so prevent escape of gas past the bullet and avoid the troubles that arise from such a cause. This expansion of the base of the bullet is known as "set up."

In the United States metallic fouling has now been practically eliminated by the substitution of a jacket metal composed of copper 90 parts, zinc 10 parts, for the usual cupro-nickel jacket.

Stream-line Bullets.—A bullet of stream-line contour has of recent years come into prominence, and is employed by Switzerland and in the United States. Its great merit is that, owing to its shape, it far outranges the bullet having a cylindrical body and tail. Owing however to its tapering tail, which precludes the possibility of "set up," the difficulty of sealing the grooves against the gas pressure developed has not as yet been so generally overcome, that such bullets, made in mass production, will continue to shoot accurately as the barrels suffer wear.

Armour-piercing.—Armoured vehicles are no doubt still in the early stages of development, and the means to counteract them is yet to seek. It seems unlikely that reliance can be placed in the machine gun of the usual bore for this purpose, and that other or heavier weapons, possibly of an automatic nature, will be developed which will be able more adequately to deal with such vehicles. Allied to this problem is that of increasing the penetrative power of armour-piercing bullets. For penetration, a hard projectile having a high velocity is essential, but a difficulty still to be overcome is the tendency of the very hard bullet to splinter without penetrating.

Capacity to vary the rate of automatic fire has much to recommend it and should be capable of accomplishment. Until now, the only machine gun in which such a regulator is embodied is the French St. Etienne (Puteaux), since superseded by the Hotchkiss.

SMALL HOLDINGS. The term "small holding" was first given an arbitrary definition by the British Parliament in the Small Holdings Act of 1892. This empowered county councils to acquire land for the provisions of "small holdings"—*i.e.*, holdings of not more than 50 acres in extent, or exceeding £50 in annual rateable value. (This sum was increased in 1926 to £100.) But "legal definitions and arbitrary size limits have no relation—or at most a very rough relation—to economic facts." All holdings of agricultural land fall into one of three classes from the economic point of view, viz.—

1. Those which are cultivated personally by persons whose living is earned otherwise.
2. Those which are cultivated by the occupier (whether owner or tenant) and his family without help—or with only the occasional help—of hired labour.
3. Those which can only be cultivated with the regular help of hired labour.

The term "small holding" is sometimes applied to the first class—to which however in Great Britain the term "allotment" is more generally applied—but it is to the second class that it is properly confined. In other words a small holding is a "subsistence" or "family" holding. It is, throughout the Continent, and over the greater part of the rest of the world where settled agriculture exists, the predominant form of land occupancy. There are in most continental countries a number of large farms (although post-war legislation has in some countries markedly reduced them) but small holdings represent the agrarian system of the greater part of Europe, as well as of India, Japan and China. In England under the feudal system, the typical holding was that of the villein, consisting of a number of detached strips in the common-field, but there were from the first in most manors, but more so in some parts of the country than others, a number of separate small holdings in exclusive occupation. As copyhold tenure gradually extended the number of small holdings increased.

The Decline of British Small Holdings.—For centuries in England, throughout the prolonged modification and ultimate disappearance of the feudal system, there was probably, on the whole, a gradual increase in the number of independent small holdings, mostly owned by the occupiers, or, in the case of copyhold holdings, held in quasi-ownership. The progress of the movement was interrupted from time to time, notably by the Black Death and in the enclosing and land-grabbing period of the 15th and 16th centuries. But it is generally agreed by economic historians that on the whole the distribution of agricultural land in small holdings, or "family" farms, continued more or less progressively down to the last great enclosure movement, which began in the latter part of the 18th century.

In a modern work on enclosure it is stated that "the movement for the enclosure of arable open and common fields has been a movement for the sweeping away of small holdings and small properties." This might be expressed differently as it is hardly justifiable to suggest that the abolition of small holdings was the chief object of enclosure. But whatever may have been the intention there is no doubt that the result was a drastic reduction in the number of small holdings. Thousands of small holdings consisted of a few acres of land attached to a cottage which gave rights of common. The common provided pasturage for cattle (in limited numbers) and for a horse or donkey, and without this the successful carrying on of the small holding was impossible. When the common was enclosed an allotment of land pro-

portionate to his interest was made to the commoner, but this in many cases was little more than a mockery. The piece of land allotted might be far from his cottage, and as the obligation to fence it rested on the allottee it was of little value and an offer from a larger landowner to buy it was usually accepted. Thus the small holding disappeared and the small holder became a labourer.

The Revival of Small Holdings.—As the conscience of the nation began to awaken after the period of callous materialism which distinguished the industrial revolution, the social and agrarian consequences of the decline of small holdings aroused attention. A few landowners provided facilities for the acquisition of small holdings by offering land in convenient quantities on easy terms. Associations were also formed by well-meaning, but in some cases ill-advised, persons to stimulate the formation of "colonies" of small holdings, the most famous being the National Land Company started by Feargus O'Connor in 1845. This company bought five estates in different counties—Oxford, Gloucester, Worcester and Hereford—cut them up into two, three and four acre lots with a house on each, and made the necessary roads and fences. Shares were offered, each carrying the right to ballot for priority in the allotment of land. In three years more than £90,000 was subscribed by 70,000 persons. The financial basis was unsound and in 1851 the company was dissolved and the estates passed into the hands of a receiver. Miss Jebb set out the reasons for failure as follows: (1) the fact of the original settlers being all townsmen ignorant of agriculture; (2) that they were established under conditions in which it would have been impossible even for an agriculturist to gain a livelihood; (3) the purchase of unsuitable estates, partly owing to the want of practical knowledge on the part of the directors themselves and partly to the great hurry in which land was bought to satisfy the clamours of shareholders; (4) the financial difficulties which arose partly from the scare of the shareholders on finding that the company was illegally constituted. Many other efforts were made, with varying success to provide land for small holdings but the difficulties were great.

One misconception was common among those whose personal knowledge of rural England was restricted. Many of them seemed to think that a small holding was an exotic plant and that the possibility of establishing it in this country required demonstration. In fact in many districts small holdings are indigenous. The nature of the country, soil, situation and climate have determined from time immemorial that only small farms can be successfully managed. Typical districts of this character are the West Riding and large parts of Devon, Cornwall and Lancaster. In the West Riding 70% of the holdings are under 50 acres. The Evesham district of Worcestershire and parts of the eastern counties afford instances of groups of small holdings which have been naturally formed in recent times by the influence of new economic conditions.

State Action.—On the basis of the report of a departmental committee of 1899, which reported in 1890, the Small Holdings Act was passed in 1892. It gave power to county councils to purchase land and adapt it for small holdings which were to be let or re-sold on a deferred payment system. One-fifth of the purchase money was to be paid down and the rest with interest to be paid off in a term not exceeding fifty years. Any elector could petition the county council alleging a demand for small holdings. The council were then to appoint a small holdings committee to enquire into the demand and if it was found to be made "in good faith and on reasonable grounds" to take measures to acquire suitable land in the district. They were empowered to spend a sum not greater than the proceeds of a rate of 1d in the £. Money could be borrowed from the public works loan commissioners at 3½%. If unable to purchase land the council were empowered under certain conditions to take it on lease. The results of this legislation were in fact disappointing.

The Act of 1908.—A much more comprehensive enactment was the Small Holdings and Allotments Act, 1908. This introduced the principle of central initiative and supervision. The Board (now the Ministry) of Agriculture was empowered to appoint small holdings commissioners who were to ascertain the extent to which there was a demand for small holdings in the several counties, or would be a demand if suitable land were available, and the extent to which it was reasonably practicable to satisfy the demand. With this object the commissioners were to confer with county councils and after due deliberation were to report to the board whether it was desirable to adopt a scheme for the provision of small holdings in the county. If they so reported a scheme was to be prepared by the county council, or in their default, by the commissioners, specifying, *inter alia* (a) the localities in which land was to be acquired for small holdings; (b) the approximate quantity of land to be acquired, and the number, nature and size of the small holdings to be provided in each locality; (c) whether and to what extent grazing or other similar rights should be attached to the small holdings. A scheme when adopted and approved by the board was to be carried out by the county council concerned, the board having power, if the council declined or neglected to do so, to carry it out and to charge the cost to the county fund.

County councils were by this act given power to acquire land compulsorily for small holdings if they were unable to obtain land suitable for the purpose on reasonable terms by agreement. The financial limitation of the Act of 1892—*i.e.*, that the annual charge on the county should not exceed the amount produced by a rate of 1d in the £—was continued. Under this act about 14,000 small holders were settled on the land as tenants of county councils. One-sixth of the holdings were provided with houses. The sinking fund was included in the rent paid by the occupier and criticism was aroused by the fact that the occupier had thus to pay the purchase money, although the land remained the property of the County Council.

Ex-service Small Holdings.—The outbreak of the World War suspended operations under the Act of 1908 and the commissioners were given other duties. After the war the subject was regarded from a new angle. The main object of the Small Holdings Colonies Act 1916 and 1918 was to provide small holdings on specially favourable terms for ex-service men, and particularly to promote the establishment of "colonies," *i.e.*, groups of small holdings, which would facilitate co-operation among the small holders. Difficulties arose in connection both with the acquisition and equipment of suitable land and also from the total unacquaintance, in many cases, of applicants with rural conditions. Another act—the Land Settlement Facilities Act—was passed in 1919 to give further powers and simplify the somewhat complicated administrative machinery.

The net result of the effort was that a number of ex-service men were settled on the land at a lavish expenditure of public money, the total cost to the exchequer being about £10,000,000. The purchase of land began just when extravagantly high prices were being realized in the boom of 1919–20. The average rate of interest on loans was 6½%, and the cost of building and general equipment was at its maximum, and about double that of pre-war times. Many ex-service men, disappointed and discouraged by the delays, withdrew their applications. Those who obtained holdings were in many cases wholly inexperienced in farming, and had at once to face a period of steadily falling prices which ruined many old-established farmers.

The Act of 1926.—The scheme for the settlement of ex-service men on the land under the Act of 1919 came to an end on March 31, 1926. Under the scheme 16,500 small holdings were provided by county councils and county borough councils on an area of 256,000 acres. But it was explained by the minister of agriculture as the justification for further legislation, that there were known to be not less than 6,000 approved applicants who had not been provided with land, and that there was a further latent demand, the extent of which could not be estimated. There was, however, the minister stated, "no practical possibility under present financial conditions, of satisfying the demand for further small holdings either under the Act of 1919, or the Small Holdings and Allotments Act, 1908, owing to the statutory requirement that councils must only provide holdings on a self-supporting basis."

The previous acts although providing certain facilities for the purchase of small holdings were mainly directed to the provision

of holdings to be let to the small holders. They tended to discourage purchase and encourage tenancy by the fact that a small holder wishing to buy his holding had to pay its full value over a term of years, with interest at the current rate on the deferred payments, whereas a tenant occupies his holding at a fair rent, which may bear no relation to the capital value and still less to the actual cost of providing it. The object of this act was to offer applicants desirous of becoming owners terms equally favourable to those open to tenants. The act continued the existing powers and duties of county councils but authorized them if necessary to incur losses, which would be met up to 75% by the Treasury. The holdings may be let or sold. If let a "full fair rent," *i.e.*, the amount a tenant might reasonably be expected to pay if the landlord did the repairs, is charged. If sold the price paid takes the form of an annuity equal to the "full fair rent" of the holding, payable in half-yearly instalments for a term of 60 years.

Cottage Gardens.—The terms "small holdings" and "allotments" have long been in use, but the Act of 1926 instituted a new class. County councils are empowered to provide holdings comprising a dwelling house together with not less than 40 perches and not more than three acres of agricultural land which can be cultivated by the occupier of the dwelling house and his family. "Cottage holdings" are to be sold to the occupiers in consideration of the payment of an annuity equal to the "full fair rent" for a period of 60 years. Only a *bona fide* agricultural labourer or person employed in a rural industry is qualified to become a purchaser. The county council has to be satisfied that he has the intention, knowledge and capital to cultivate satisfactorily the land forming part of the cottage holding. The term "rural industry" is defined as an industry carried on in or adjacent to a village, being an industry ancillary to the industry of agriculture or horticulture.

Public Landownership.—One result of the English small holdings legislation is that county councils are now extensive owners of agricultural land. The power of acquisition was conferred in 1908 and in the aggregate a considerable area is under the control and administration of the councils. At the end of Nov. 1924, 384,052 acres were in the possession of the English counties, the amount ranging from 27,861 acres held by Norfolk and 26,257 acres held by Somerset to 219 acres held by Westmoreland. Of the total area administered by the English counties about four-fifths is owned by them, the other fifth being held on lease. In Wales about 58,000 acres are administered under the act, making altogether about 442,000 acres in England and Wales. Nothing more forcibly demonstrates the progress of public opinion than this large transfer of agricultural land from private to public ownership and the fact that it has been done by general consent.

The Economics of Small Holdings.—The relative advantages of large and small farms have long provided a field for animated controversy. The arguments in favour of the large farm are forcible. They are given in a recent work and may be quoted:—

> In the production of all commodities for which there is a large and constant demand the tendency is to make the fullest possible use of machinery. The profitable use of machinery depends on the relation of its output to its prime cost. If it can be used up to its maximum capacity the maximum profit from its use is obtained. In the case of agricultural machinery and implements it is impossible to use them to their maximum capacity because farming operations, unlike those of manufacture, cannot be continuous but are dependent on uncontrollable conditions such as the time of year and the weather. A steam plough for example, is capable of working every day in the year but it can only be used on a certain number of days. On a "medium-sized" farm its use is restricted not only by such conditions but also by the limited area on which it can be usefully employed. By extending the area of the holding the farmer has sufficient land to use the plough to its maximum capacity at all times when conditions permit. This applies to the whole mechanical equipment of the farm, though with less force to stationary engines which can supply motive power for various operations, some of which, like chaff-cutting, can be done at all times of the year. Somewhat similar considerations apply to manual as to mechanical power. With a large staff labour can be more effectively organized and work specialized. Shortly, the advantage of the large-scale farm, as of the large-scale manufactory or shop, is that overhead expenses are charged to a larger output.

The small holder has none of these advantages. He is frequently inadequately equipped with implements and machinery. For times of pressure such as hay-time or harvest he often has insufficient labour, both horse and manual, and has consequently to arrange with a neighbour for mutual help. If he is the tenant of a public authority or of a good landlord his cottage, buildings, fences, etc., are probably kept in good order, but if, as often happens, the owner is himself (or herself) a "small" landlord the condition of the small holding is likely to be very bad. Usually the small holder has limited capital and in marketing his produce—unless he is fortunate enough to sell it direct to the consumer—he is generally handicapped in competition with larger farmers. His life is as a rule one of unremitting toil, from dawn to dark. Yet multitudes of small holders are contented and happy in their lot, and so long as they can make a modest living do not complain.

The reason is primarily psychological. A man will work for himself without stint, whereas if he is working for another he, unconsciously or consciously, regulates his work by his remuneration. The incentive of personal reward proportionate to personal effort goes far to explain the small holder's attitude. The sociological advantages of small holdings in maintaining a class attached by the strongest of ties to the land are evident. Notwithstanding what has been said about large-scale farming small holdings have certain economic advantages of which the chief is the close personal supervision of the farmer himself. There is no doubt, that, especially where stock is kept, this is an important factor. Again the labour difficulties to which reference has been made lead the small holder to deal, so to speak, in small lots in arranging his cropping and to avoid "putting all his eggs in one basket." Thus if his gains are small his losses are never very serious.

The economic effect of the size of holdings has not been investigated. It is one of the many questions which the new science of agricultural economics (*q.v.*) must take up. The subject is complicated because in comparing one farm with another, or even one group of farms with another, it is difficult to isolate a single factor—size—from all other factors which affect output and profit. But it is commonly considered among agricultural economists on both sides of the Atlantic that "both the capital invested and the output per acre are larger on the smaller farms, but that expenses per acre are also heavier, while the output per man tends to increase with the size of the holding." The relative advantages of ownership and tenancy of small holdings have been warmly discussed in England. The position has been somewhat curious. Up to the latest act, that of 1926, the legislature definitely discouraged the purchase of holdings, while, whenever the question was tested, all the evidence tended to show that with few exceptions there was no desire to become owners and that tenancy was preferred. There were, however, many who strenuously maintained that the preference for tenancy was attributable to the unattractiveness of the terms for purchase.

That ownership provides an incentive which is absent when a man is putting his labour into land not his own has long been accepted as a self-evident proposition. Arthur Young's dictum that "the magic of property turns sand into gold" has been regarded as demonstrating the fact. Plausible as the theory is, in practice there is no evidence that there is any general superiority in production or otherwise on holdings that are owned over those that are rented. Some investigations on the point have been made, mainly in the United States. The results are not conclusive but they fail to indicate that ownership is a dominant factor. This is another subject waiting further study by agricultural economists.

SMALL ISLES, a parish of islands of the Inner Hebrides, Inverness-shire, Scotland. It consists of the islands of Canna, Sanday, Rum, Eigg and Muck, lying, in the order named, like a crescent with a trend from north-west to south-east, Canna

being the most northerly and Muck the most southerly. They are separated from Skye by Cuillin Sound and from the mainland by the Sound of Ardnamurchan. The surface is moorland, pasture and mountain. They are rich in sea-fowl, and the fisheries include cod, ling and herring. Steamers call regularly at Eigg, Rum and Canna. Antiquarian remains at Canna include a weather-worn sculptured stone cross and the ruins of a chapel of St. Columba. On the north-east coast of Eigg is a cave with a narrow mouth, opening into a hollow 255 ft. long. In it Macleod of Skye, towards the end of the 16th century, ordered 200 Macdonalds to be suffocated, their bones being found long afterwards.

SMALLPOX or **VARIOLA,** an acute infectious disease characterized by fever and eruption, which, after passing through various stages of papule, vesicle and pustule, dries up, leaving more or less distinct scars.

By far the most common cause of conveyance of the disease is contact with the persons or the immediate surroundings of those already affected. The direct cause is unknown. The disease is probably communicable from its earliest manifestations, but it is generally held that the most infectious period extends from the appearance of the eruption till the drying up of the pustules. No age is exempt from susceptibility. One attack of smallpox as a rule confers immunity, but there are numerous exceptions to this rule. Overcrowding and all insanitary surroundings favour the spread of smallpox where it has broken out; but the most influential condition is the amount of protection afforded to a community by previous attacks and by vaccination (*q.v.*). Such protection, although for a time most effectual, tends to become exhausted unless renewed. Hence in a large population there is always likely to be an increasing number of individuals who have become susceptible to smallpox. This probably explains its occasional and even apparently periodic epidemic outbreaks in large centres, and the well-known fact that the most severe cases occur at the beginning—those least protected being necessarily more liable to be first and most seriously attacked.

Symptoms.—The following description applies to an average case. Onset of the symptoms is preceded by a period of incubation, believed to be from ten to fourteen days. The invasion is sudden and severe, in the form of a rigor followed by fever (the *primary fever*), in which the temperature rises to 103° or 104° Fahr. or higher. A quick pulse, intense headache, vomiting and pain in the loins and back are among the most characteristic initial symptoms. These symptoms continue for three entire days. During their course there may occasionally be noticed, especially on the lower part of the abdomen and inner sides of the thighs, rashes resembling scarlet fever and measles, less frequently a fine haemorrhage or petechial eruption develops. These "prodromal rashes," appear to be more frequent in some epidemics than in others. On the third or fourth day the characteristic eruption begins to appear. It is almost always first seen on the face, particularly about the forehead and roots of the hair, in the form of dusky red erythematous spots which in the course of a few hours develop into true papules more or less thickly set together. The eruption spreads over the face, trunk and extremities in the course of a few hours—continuing, however, to come out more abundantly for one or two days. It is always most marked on the exposed parts. On the second or third day after the appearance of the papules they change into vesicles filled with clear fluid and show a slight central depression, giving the characteristic umbilicated appearance. The clear contents of these vesicles gradually become turbid, and by the eighth or ninth day they are changed into pustules. The fully developed pocks increase in size and lose the central depression.

Accompanying this change there are often marked inflammation and swelling of the skin, which render the features unrecognizable. The eruption is also present but in a modified form on the mucous membranes, that of the mouth and throat being affected early, and the swelling produced here is a source of danger, from obstruction in the upper air-passages. The mucous membrane of the nostrils may be similarly affected. The eyes may also be involved, to the danger of permanent impairment of sight. The fever which ushered in the disease quickly returns to normal on the first appearance of the eruption but when the vesicles become converted into pustules, there is a return of the fever (*secondary* or *suppurative fever*), sometimes accompanied by great restlessness, delirium or coma. On the eleventh or twelfth day the pustules begin to dry up and the febrile symptoms decline. Great itching of the skin attends this stage. The scabs produced by the dried pustules gradually fall off and reddish brown spots remain, which leave permanent white depressed scars—this "pitting" so characteristic of smallpox being specially marked on the face. Convalescence in this form of the disease is as a rule uninterrupted. In the majority of the cases developing in the United States during recent years no secondary fever has been seen.

Varieties.—When the pocks are separated from each other, with clear spaces between, the disease is called discrete or distinct smallpox; when the pocks run together, confluent smallpox. There are two forms of haemorrhagic smallpox: 1, always fatal when haemorrhage into the skin and mucous membranes occur (Purpura variolosa, black smallpox); 2, benign when the haemorrhage takes place inside the pustule (Variola hemorrhagica pustulasa).

Recent Investigations.—Since about 1910 much knowledge of the nature of this disease has accrued in the course of attempts to discover the causal organism. This has been sought, though fruitlessly, in many direct investigations of the rash and of the blood by microscopical examination and by attempts to inoculate animals. The failure is explained, in part, by the discovery that the virus of vaccinia and smallpox belong to the group of filter-passing viruses (*see* FILTER-PASSING VIRUSES). Considerable interest centres around the discovery of the so called *Cytoryctes variolae* and *vaccinae* described by Guarnieri in 1892. Jenner believed that cowpox (vaccinia) and smallpox (variola) have the same origin and nature. But attempts to inoculate the cow with smallpox matter failed and Jenner's opinion was not substantiated until Monckton Copeman and others proved that the virus of smallpox can be inoculated in the cow by a process of transmission or passage and that in the cow, under these conditions, typical lesions of vaccinia are produced. But although vaccinia is the same disease as smallpox, during its passage through the cow it has lost the power of producing bacteriemia in man though it induces the typical lesion at the site of inoculation and by means of this local lesion, protects the vaccinated individual against the major infection from which the vaccine matter was derived.

Establishment of the homologous relationship between variola and vaccinia widened the field of investigators into the nature of the contagium of smallpox by providing a material, viz., vaccine lymph, which is at once abundant and easily produced. By experiments on the rabbit, which is susceptible to vaccinia, the immunity conferred by vaccinia has been studied and it has been shown that specific antibodies are produced in the blood and tissues of the vaccinated animal similar to those produced in typhoid fever and cholera, and that the antibodies in vaccinia and variola are apparently identical. It has been claimed, though on insufficient grounds, that this identity affords a means of certain diagnosis of the disease in doubtful cases of smallpox.

Serum Therapy.—In so far as the therapeutic application of the knowledge thus acquired is concerned, it has been shown that the serum of animals immune to vaccinia not only has protective power against vaccinia but also is possessed of curative properties because it destroys the virus of vaccinia *in vitro*. Whether this curative property is susceptible of increase by means of a graduated increase of dose of virus has not been investigated. In France, the serum of convalescent smallpox patients has been used in treatment and it is claimed that an undoubted curative result was obtained in cases which from clinical experience would almost certainly have proved fatal. But so far the virus of smallpox has not been obtained in quantity sufficient to permit of the attempt to manufacture a therapeutic serum, nor has it been shown that the immunity of an animal to vaccinia can be raised to a degree which might make its serum of value in the treatment of smallpox.

Polyvalent vaccines and serum prepared from pyogenic organisms have been used with some success in the treatment of severe confluent smallpox. This treatment is based on the assumption

that the severity of the later stage of the illness in confluent smallpox, *i.e.*, the stage of maturation or pustulation of the rash with the secondary fever of the disease, is closely associated with a secondary pyogenic infection.

Incidence in Europe During Recent Years.—The mode of spread of smallpox may be illustrated by a short account of the incidence of the disease in Europe from 1910 to 1924. It is convenient to divide the period into three quinquennia:—1. 1910–4, the period preceding the World War; 2. 1915–9, the period of the War; 3. 1920–4, the period of gradual recovery from the War.

During the first quinquennium no satisfactory arrangement existed among the European powers for the interchange of information concerning the incidence of epidemic diseases, and particularly from large areas where the disease is endemic and vaccination negligible, such as Spain, the Balkan States, Turkey and Russia, information concerning the rise and fall in incidence or even of serious epidemic extensions of the disease was scanty and unreliable. During this quinquennium the disease was very prevalent in Italy where a severe epidemic occurred in 1911–2. On the other hand, in France, Belgium, Austria, Germany, Denmark, Holland and the Scandinavian countries, smallpox was a rare disease as it had been since the beginning of the century. In England and Wales no extensive epidemic had occurred since the outbreak of 1902–3–4 and in the five years' period before the War only 88 deaths from smallpox were recorded in Great Britain.

With the outbreak of war in 1914, the decline was arrested and the movement of armies and migration of civil population to and from the endemic centres in the east of Europe rapidly made itself felt by an uncontrolled and increasing spread of smallpox which reached its greatest intensity in 1919. At the end of 1914 and throughout 1915 severe epidemic smallpox carried by prisoners of war from Russia and refugees occurred in the states of the old Austrian Empire which bordered on Russia and also in the Balkans. Similar agencies scattered the infection throughout Germany and in 1916–7 there were outbreaks in Hamburg and other western towns. The incidence of the disease in Germany rose continuously throughout the years of the War. Over 2,000 cases were recorded during 1917 and upwards of 5,000 during 1919. The infection reached Sweden on more than one occasion and a few cases occurred in Norway. In the Netherlands at least one serious outbreak occurred.

The experience of France during the war period was remarkable. The serious epidemic which swept over the country during the war of 1870–1 had not been forgotten and the French army of the World War was efficiently protected by vaccination. The invading German troops were also protected and no doubt acted as a screen to France on the east. Throughout the country, with the exception of districts on the Mediterranean coast and bordering on the Spanish frontier, the incidence amongst the civil population was low during the War. The freedom of France was reflected in the freedom of England during this period. The British army, like the French, was vaccinated and therefore in contrast to the experience of England in 1870–71, and in spite of the enormous volume of cross-channel traffic, only a small amount of smallpox infection reached England through France. In the later years of the War the revolution in Russia sent many refugees into England who brought the infection via Scandinavia and the Murmansk coast. But the close guard maintained on the North Sea ports of Britain and the vigilance of her public health authorities prevented any serious attack on the civil population in spite of the increasing neglect of vaccination among the people.

Post-War Incidence.—In the third quinquennium, 1920–4, the bureau for the service of epidemiological intelligence and public health statistics was initiated under the authority of the League of Nations for the purpose of collection and interchange of information concerning epidemic diseases. The annual report from this source for 1924 deals with 29 European, 17 African, 20 American, 16 Asiatic countries and Australasia, and shows that in Europe smallpox incidence has diminished year by year since 1919. The effects of the War on the incidence of the disease in Russia and neighbouring countries, viz.: Czechoslovakia, Rumania, Austria, Poland, Finland and Germany reached their culminating point in 1919 and since that year the decline in prevalence in all these countries has been continuous and rapid. Similarly in Italy, where 34,365 cases were recorded in 1919, only 190 cases occurred in 1924. Although Spain continues to be the chief endemic centre in the west of Europe, the recorded deaths from smallpox in that country fell from 3,620 in 1919 to 1,214 in 1924. During the quinquennium England and Switzerland were the only European countries in which the incidence rose. In Switzerland the figure for 1924 shows a fall but in England the increase was progressive to the end of the period as seen by the following table:—

Number of cases of smallpox recorded .	1919	1920	1921	1922	1923	1924
In England and Wales .	294	263	315	973	2,485	3,765
In Switzerland . .	3	2	596	1,153	2,126	1,234

In both countries the mild type of the disease, associated with the almost complete absence of fatality, led to the concealment of cases and an increasing neglect of vaccination.

Variation of Epidemic Type.—Outbreaks of smallpox, like those of other infectious diseases, vary in their lethal power. In 1789 Jenner described an outbreak which occurred about seven years before in Gloucestershire, "of so mild a nature that a fatal instance was scarcely ever heard of . . . I watched its progress upward of a year without perceiving any variation in its general appearance. I consider it then as a variety of smallpox."

Observers in different parts of the world have directed attention to the occurrence of outbreaks which apparently resemble the one described by Jenner. An outbreak in South Africa was described by de Korté in 1904, under the name of Amaas or Kaffirpox, another by Ribas in Brazil in 1910, under the name of Alastrim, and others of a similarly mild character have been recorded in the United States, the West Indian Islands, Australia, and, as mentioned above, in England and Switzerland.

The opinions of many modern observers differ from that of Jenner who was satisfied in calling his outbreak a "variety of smallpox." That the form of disease observed in so many parts of the world belongs to the smallpox group is common ground. But some observers hold that it is more closely allied to chickenpox than to smallpox; others differentiate it from both diseases and regard it as a newly identified member of the group, while others maintain that it is a hybrid of smallpox and chickenpox, a true varioloid-varicella. On the other hand the weight of medical opinion in England inclines to the view that the disease is simply a mild type of smallpox.

Differentiation of the smallpox eruptions similar in type has become more certain and rapid through the work of Ricketts. Ricketts' thesis is that the focal rash of smallpox has a characteristic distribution governed by two complementary factors, viz.: exposure to irritation and protection against irritation, which determine a relative increase and decrease of the incidence of the rash on any part of the skin surface. These factors are independent of the course of the disease and of the evolutionary changes which constitute the features of the rash. They are also independent of modification of these changes resulting from variation in immunity possessed by the patient or of variation in the toxic power of the infecting virus. They have the further advantage of being objective and therefore less liable to confusion in interpretation than any others. They begin to be established with the beginning of the outcrop of the rash, are fully established when eruption is completed and remain unchanged as long as the rash lasts.

Blaxall, Cleland and Ferguson, Green and Gordon in England, and Leake and Force in America, have experimented on lower animals with material from the mild disease and also with material from severe cases of acknowledged smallpox, in order to determine what differences, if any, exist between the two conditions and in their immunological relations to each other and to vaccinia. The results of these investigations have been sum-

marised by Ledingham, and confirm the opinion that the mild disease as it exists in England is smallpox of which the virus has lost a degree of its toxicity for man but retains its important properties for other animals. The distinction between the two viruses is one of lethal power only and the factors which govern this property are unknown. Over five years' experience in England of a widespread infection by the mild type of smallpox has afforded very little, if any, evidence of a tendency to increase in virulence. But in the absence of knowledge of the cause of variation in lethal power or of the natural conditions which may favour its occurrence, it is unsafe to assume that a low degree of virulence is a permanent feature of this type of smallpox and on that assumption to relax the stringency of administrative precautions against the disease.

Smallpox cases as reflected in the U.S. Public Health Reports show a seasonal fluctuation, with an upward tendency in the U.S. during 1927–28. In analogous centres of civilization in Europe and the United States, the former shows a greater control of the disease due to the fact that state officials in Europe have an organized system of inspection and the machinery for compulsory carrying out of regulations, not yet established in the United States. Vaccination of children and revaccination of adults is stressed by French and American authorities as essential to the restraint of the disease.

SMALTITE, a mineral consisting of cobalt diarsenide, $CoAs_2$. It crystallizes in the cubic system with the same hemihedral symmetry as pyrites; the rare crystals have usually the form of cubes or cubo-octahedra; but more often the mineral is found as compact or granular masses. The colour is tin-white to steel-grey, with a metallic lustre. Hardness 5·5; specific gravity 6·5. The cobalt is partly replaced by iron and nickel, and as the latter increases in amount there is a passage to the isomorphous species chloanthite ($NiAs_2$). It occurs in veins with ores of cobalt, nickel, copper and silver. Smaltite was early used in the preparation of smalt for producing a blue colour in porcelain and glass. (L. J. S.)

SMART, CHRISTOPHER (1722–1771), English poet, was born at Shipbourne, Kent, on April 11, 1722. His father was steward for the Kentish estates of William, Viscount Vane, younger son of Lord Barnard of Raby Castle, Durham. Christopher Smart went to school at Maidstone, and at the Durham grammar school of Durham. He spent part of his vacations at Raby Castle, and his gifts as a poet gained him the patronage of the Vane family. Henrietta, duchess of Cleveland, allowed him a pension of £40 which was paid until her death in 1742. At Cambridge, where he was entered at Pembroke College in 1739, he spent much of his time in taverns, and got badly into debt, but in spite of his irregularities he became fellow of his college, praelector in philosophy and keeper of the common chest in 1745. In November 1747 he was compelled to remain in his rooms for fear of creditors. About 1752 he left Cambridge for London, though he kept his name on the college books. He wrote in London under the pseudonym of "Mary Midnight" and "Pentweazle." He had a hand in many journalistic undertakings, and completed a prose translation of Horace. Some criticisms made by "Sir" John Hill on his *Poems on Several Occasions* (1752) provoked his satire of the *Hilliad* (1753), noteworthy as providing the model for the *Rolliad.*

In 1751 Smart had shown symptoms of mental aberration, which developed into religious mania, and between 1756 and 1758 he was in an asylum, where he was visited by Johnson, who thought him sane. The poem written by him in the asylum, "A Song of David," is his only famous work, and has been compared by some critics to the work of Blake. After his release Smart produced other religious poems, but none of them shows the same inspiration. For some time before his death, which took place on May 21, 1771, he lived in the rules of King's Bench, and was supported by small subscriptions raised by Dr. Burney and other friends.

From the *Poems of the late Christopher Smart* (1791) the "Song to David" (pr. 1763) was excluded. It was reprinted in 1819, and in an abridged form is included in T. H. Ward's *English Poets,* vol. iii.; it was reprinted in 1895, and in 1901 with an introduction by R. A. Streatfeild.

SMART, SIR GEORGE THOMAS (1776–1867), English musician, was born in London, his father being a music-seller. He was a choir-boy at the Chapel Royal, and became violinist, organist, teacher of singing and conductor. From 1811 onwards Sir George Smart was one of the chief musical leaders and organizers in England, conducting at the Philharmonic, Covent Garden, the provincial festivals, etc., and in 1838 he was appointed composer to the Chapel Royal. He was a master of the Handelian traditions, was personally acquainted with Beethoven and a close friend of Weber, who died in his house. Much of his church music is still heard in the churches. He died in London on Feb. 23, 1867.

SMART, JOHN (*c.* 1740–1811), English miniature painter, was born in Norfolk; he became a pupil of Cosway, and is frequently alluded to in his correspondence. This artist was director and vice-president of the Incorporated Society of Artists, and exhibited with that society. He went to India in 1788 and obtained a number of commissions in that country. He settled down in London in 1797 and there died. He married Edith Vere, and is believed to have had only one son, who died in Madras in 1809. He was a little man, of simple habits, and a member of the Society of Sandemanians. Many of his pencil drawings still exist in the possession of the descendants of a great friend of his only sister. Several of his miniatures are in Australia and belong to a cadet branch of the family. His work is entirely different from that of Cosway, quiet and grey in its colouring, with the flesh tints elaborated with much subtlety and modelled in exquisite fashion. He possessed a great knowledge of anatomy, and his portraits are drawn with greater anatomical accuracy and possess more distinction than those of any miniature painter of his time.

See *The History of Portrait Miniatures,* by G. C. Williamson, vol. ii. (1904). (G. C. W.)

SMEATON, JOHN (1724–1792), English civil engineer, was born near Leeds on June 8, 1724, the son of an attorney. He was educated at Leeds grammar school, and employed in his father's office, but in 1742 became apprentice to an instrument maker. In 1750 he set up in business on his own account. Besides improving various mathematical instruments used in navigation and astronomy, Smeaton experimented in regard to other mechanical appliances, amongst the most important being a series on which he founded a paper—for which he received the Copley medal of the Royal Society in 1759—*An Experimental Inquiry concerning the Native Powers of Water and Wind to turn Mills and other Machines depending on a Circular Motion.* In 1754 he studied the canal works of foreign engineers in the Low Countries. He rebuilt Eddystone lighthouse in 1759, and prepared designs for engineering projects, including the construction of canals (especially the Forth and Clyde canal), and harbours, the drainage of fens, the repair and erection of bridges, though capital was not always available to carry out his schemes. He also designed many windmills, pumps, and other mechanical appliances. He devoted much of his time to astronomical studies and observations, on which he read various papers before the Royal Society. He died at Austhorpe on Oct. 28, 1792, and was buried in the parish church of Whitkirk.

He published the *Narrative of the Building of the Eddystone Lighthouse* (1791). See J. Holmes, *A Short Narrative of the Genius, Life and Works of the late Mr. John Smeaton* (1893); and S. Smiles, *Lives of the Engineers* (rev. ed. 5 vols., 1874).

SMEDEREVO (German, *Semendria*), an important commercial town, and capital of the Smederevo department of Serbia, Yugoslavia. Pop. (1921), 6,296. It is a walled town on the Danube, and is a regimental and artillery headquarters. There

is a good quay, and grapes, white wine, oils, livestock, pigs and cereals are exported. The only manufacture is that of railway trucks. Smederevo is believed to stand on the site of the Roman settlement *Mons aureus,* and there is a tradition that its famous vineyards were planted by the Roman emperor Probus (A.D. 276–282). In the 15th century when the Serbian prince, George Brankovich, became lord of Tokay in Hungary, he planted vines from Smederevo on his estates there, and from these came the famous white wine of *Tokay.* Close to the river is a mediaeval castle, with nineteen square towers, built by George Brankovich in 1430, with a large cross built in, in red bricks. Under the surface of the walls are representations of three heads showing only the eyes, nose and mouth, and probably connected with the sacrificial practice of entombing individuals during the building. Smederevo was the capital of Serbia from 1430, when Belgrade was captured by the Turks, to 1459. Kara George, the leader of the first Serbo-Turkish rising, was murdered here in 1817, and the town, which has no modern defences, was bombarded in the World War (1914–18).

SMELL AND TASTE. The flavours of our food are mingled tastes and smells in which we seldom distinguish sharply one set of sensations from the other. If the nose is closed by being firmly held between the fingers, and food is then put into the mouth, taste is the only sense excited. Under such restrictions we can recognize four classes of sensations, all tastes, sour, sweet, saline, and bitter, and possibly two others, alkaline and metallic. These tastes singly or in combination yield all that may be said to be contributed by this sense to the flavours of our food. Such a contribution is relatively small and shows that flavour, contrary to common opinion, is much more a matter of smell than of taste.

TASTE

Four Chief Tastes.—In man taste may be excited from most surfaces of the mouth and the pharynx, the chief exceptions being the floor of the mouth, the gums, the hard palate, and the inner surfaces of the cheeks. The principal region for taste is the upper surface of the tongue, and the four principal tastes are differently distributed on this surface. Sour is best developed on the sides of the tongue, saline on the sides and tip, bitter at the base, and sweet at the tip.

All surfaces of the mouth from which taste may be elicited are provided with taste-buds and such buds are limited to these parts. Each taste-bud is a microscopic group of cells bud-shaped in outline whose free, bristle-like ends project into a pore that opens on the surface of the tongue; the deep ends of these cells are associated with nerve fibres that lead to the brain. There is no special nerve of taste but the fibres concerned with this sense enter the brain through at least two nerves, the seventh or facial nerve for those from the tip and sides of the tongue and the ninth or glosso-pharyngeal nerve for those from the base of that organ.

Sour tastes are excited by acids in watery solution. When an acid is dissolved in water its molecules break up into part-molecules or ions and in aqueous solutions of acids one of these is always a hydrogen ion. Hence hydrogen ions are believed to be the exciting agents for the sour taste. In a similar way the saline tastes are believed to be called forth by chlorine, bromine, and iodine ions which are produced when the appropriate salts are dissolved in water. The two remaining tastes are as a rule not excited by ions but by whole molecules, the bitter tastes chiefly by the alkaloids such as quinine, strychnine, and the like, and the sweet tastes by the alcohols, and particularly by the sugars. Sweet tastes are also excited by saccharine which, though an organic compound, is chemically quite unrelated to the alcohols or to the sugars, and by the inorganic substance lead acetate which in consequence of this peculiarity is often called sugar of lead.

Taste-buds.—When taste-buds are tested locally some are found to be excited only by acid solutions and to give rise only to the sensation sour; others are exclusively saline and still others sweet. The same rule probably holds for the bitter taste but thus far the exclusive relation of a special set of taste-buds with this sensation has not been fully demonstrated.

It seems probable, however, that there is a particular type of taste-bud for each of the four or more classes of taste sensations. These types of taste-buds must differ chemically one from another. Thus the free tips of sour buds must be so constituted chemically as to react with acid solutions but not with solutions of salts, of sweet substances, or of bitter substances, and a corresponding relation must obtain in the other types of taste-buds. Ordinarily one class of chemical substances may be expected to be the means of excitation for one class of taste-buds and such seems to be generally true, but it is conceivable that on the basis of the analysis just given a single substance may be so constituted as to excite two or more classes of buds and thus possess an equal number of tastes. This appears to be true of parabrombenzoic sulphinide which is sweet when applied to the tip of the tongue and bitter at its base.

The Functions of Taste.—Taste is thus essentially a chemical sense in which the materials tasted are in aqueous solution and as such react with the taste-buds, the classes of which are as numerous as the classes of taste sensations. Taste, therefore, is in reality a complex sense in which there are at least four subsenses each with independent terminals and separate sensations. It would be entirely appropriate to speak of a sense of sour, of sweet, of saline and of bitter.

Taste is naturally a most important sense for the choice of food; by means of it animals are enabled to select from the various materials available to them what is appropriate for their nourishment. Organs of taste are therefore commonly found in or about the mouths of most creatures especially in close relation with those parts by which the food is crushed and its juices thereby freed. In some fishes, as for instance the catfishes, taste-buds occur not only in the mouth but on the long oral tentacles and even over much of the body.

The organs of taste are also of great importance in initiating digestive operations. Through them may be excited the flow of salivary juice and of other digestive secretions; the act of swallowing and other movements of the digestive organs, all of which constitute very important steps in the appropriation and assimilation of food, may also be started directly or indirectly through taste.

SMELL

The Olfactory Organ.—The organ of smell in man is located in the nose. The delicate membranous lining of the uppermost part of the nasal chamber is different in colour from that of the rest of the chamber and is the true olfactory organ. The area covered by this organ in each nasal chamber is approximately one square inch. From this membrane nerve fibres gather together, thus constituting the first or olfactory nerve, and make their way directly into the brain. Each nerve fibre comes from a sense cell which forms a part of the olfactory organ and all such cells reach through this organ to its outer or exposed face. Here each cell terminates in six to eight relatively long filaments, the so-called olfactory hairs which float in the thin layer of aqueous mucus that covers the olfactory surface. This mucus is in direct contact with the air of the nasal cavity in which is carried the odorous particles.

In ordinary breathing the respiratory air passes in and out through the lower part of the nasal chamber without passing up into the region of the olfactory organ. Hence under such circumstances we are not as a rule cognizant of odours. If, however, our suspicions are aroused we ordinarily sniff, an operation that draws the passing air into the upper part of the nasal chamber and thus brings it into contact with the olfactory surface. Here the odorous particles may be caught on the moist mucous surface to make their way ultimately to the olfactory hairs.

Two Kinds of Response.—As may be inferred from this account the lower portion of the nasal chamber is respiratory and only its uppermost part is olfactory. Nevertheless the whole surface of the chamber is in a way sensitive, for the fifth or trigeminal nerve is distributed throughout it. This nerve, once supposed to have to do with smell, is now definitely known to be

concerned with irritants. If the olfactory nerve in a dog is destroyed, the animal will still sneeze when vapour of ammonia enters its nostrils. The same is true of human beings who through disease have lost the olfactory nerve but who still retain the trigeminal nerve. Many persons who fail to recognize the more delicate odours of flowers, food, and the like are nevertheless readily cognizant of even minute quantities of chlorine, ammonia and other like substances. These materials are not odorous materials in the proper sense of the word but are irritants and affect the terminals of the fifth nerve, not those of the first nerve. True smell has to do with relatively delicate perfumes and odours and is mediated by the first nerve in contrast with irritants which stimulate the fifth nerve. It is therefore of considerable importance in the study of olfaction to distinguish between these two nervous activities.

No one has succeeded in classifying odours with anything like the precision that has been attained for tastes.

Exceeding Delicacy of Olfactory Sense.—Odorous sensations are called forth by an almost immeasurably small amount of material. A musk bean can give out the odour of musk for years without appreciably changing in weight. One of the most strongly odorous substances known is mercaptan, a liquid with the penetrating smell of garlic. When this liquid is evaporated in the atmosphere so that 50 cubic centimetres of air, enough for a single whiff, contain only $\frac{1}{460,000,000}$ of a milligram of mercaptan, the presence of this material can still be detected by smell. Although mercaptan from the standpoint of olfaction is an exceptionally effective agent, it is nevertheless true that in all other instances the actual amount of a given substance needed to excite smell is almost unbelievably small.

In consequence of this immense efficiency of the olfactory sense animals rely upon it in many of their most delicate responses. *See* SMELL AND TASTE, SENSES OF, below.

Material Basis of Smell.—The artistry of smell finds its expression in perfumes. From time immemorial man has supplemented the natural odours of his body by numerous extractives mostly from the stores of nature. These perfumes as a rule increase in delicacy with the advancement of civilization. They are used either as a means of counteracting innate objectionable odours or of adding attractiveness to the individual carrier Odours have also played an important part in the refinements of life as seen in the aroma of good tobacco and the bouquet of fine wine.

It has been supposed by some investigators that smell was induced not by material particles from the odorous substances but by exceptional and peculiar emanations from these sources. Evidence on the whole does not favour this view, but it seems more probable that what excites smell are the material particles themselves from the odorous substance. Even in very high dilutions enough of these particles seem always to be present to account for smell. Thus in the $\frac{1}{460,000,000}$ of a milligram of mercaptan, the amount necessary for a single whiff of this substance, there are estimated to be not fewer than 200,000,000,000 molecules of the substance concerned. It is these molecules dissolved in the mucous covering of the olfactory organ that attack the olfactory hairs and thus initiate nervous changes leading to the sensation of smell. Smell, like taste, is a chemical sense in that odorous materials in solution activate the living olfactory cells.

Difference Between Smell and Taste.—If smell as well as taste is a chemical sense, why are these two senses so different? This is by no means an easy question, but perhaps the most ready answer to it can be found in the peculiarities of the stimulating materials. Most substances that we smell we do not taste and most substances that we taste we do not smell. Thus sugar has a sweet taste but no odour. If we mince onion and, holding the nose, place it in the mouth we experience a sweetish taste indistinguishable from that of minced sweet apple. Apple and onion both contain sugar which has a sweet taste but no odour. The characteristic odours of onion and of apple are smells which do not affect taste. This is true of many pure substances; they are either tasted or smelled but not both. There are substances, however, that have both taste and smell. Ethyl alcohol has a sweetish taste and a characteristic ethereal odour. Again substances that we taste are predominantly soluble in water; those that we smell are more generally soluble in oil, in fact the essential oils are among the most characteristic sources of odours. But here, too, the distinction is not without exceptions.

Perhaps the most important difference between the two senses is a quantitative one; we taste only relatively strong solutions; we smell very dilute ones. This can best be demonstrated with substances that have both taste and smell. Thus ethyl alcohol can just be tasted at a concentration that is 24,000 times greater than that at which it can just be smelled, and this relation is true of most other such combinations. Quantitatively we smell extremely minute amounts of material; we taste only relatively large amounts.

As a consequence of this quantitative difference between taste and smell these two senses are commonly used in very unlike ways. In taste the stimulating material is in the mouth and we ordinarily locate it there. Again, in smell the stimulating material is likewise in the cavity harbouring the sense organ but we do not think of it as there; we project it into the exterior to the object from which the odorous particles come. In this respect smell is like sight; we do not see things in our eyes but in the exterior. Taste and other like senses are therefore called inner senses and their organs interoceptors, while the organs of smell are classed as distance sense organs or exteroceptors. What is true of the sense organs of man in this respect is true of those in other animals. These lower creatures react to taste as an affair of the mouth and to smell as something in the external environment.

Parker, *Smell, Taste and Allied Senses in the Vertebrates* (1922). (G. H. P.)

SMELL AND TASTE, SENSES OF.—The senses of smell and taste are distinguished from the rest as "chemical senses," because their sensory cells respond to chemical stimuli. In vertebrates the two senses are completely separated. *See* SMELL AND TASTE above.

In invertebrates a similarly sharp distinction between the sense of smell and that of taste is, in most cases, impossible. Insects alone possess separate sense organs which react to different chemical qualities. According to Schaller's investigations, this applies also to aquatic insects (*Dytiscus*). This is important as, formerly, it was denied that aquatic insects, in general, have a sense of smell. In gastropods, crustaceans, cuttlefishes and worms tastes and odours are perceived by the same sense organ, so that in these cases there is neither an anatomical nor a chemical differentiation. Under these circumstances, most naturalists consider it more correct to speak of only one unified chemical sense in such animals. It has an olfactory and a gustatory component. It is uncertain, and will probably always remain undecided, whether two qualitatively different kinds of sensory cells share in the constitution of such a sense, so that special olfactory and special gustatory cells are situated side by side in the same organ, or whether one and the same cell responds to both tastes and odours.

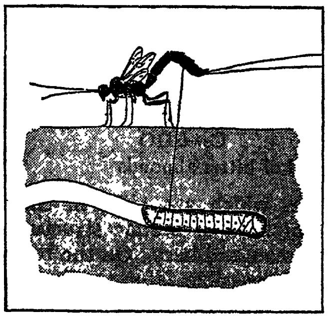
Biologically speaking, in all such cases the olfactory component naturally appears as the more important, and is much more in the foreground. It is used in the seeking out of food and mates, in the recognition of enemies, and so on, while the taste component is used only in testing the food. The use of the term "olfactory sense" in such cases is, therefore, not to be altogether rejected, as will appear from the following.

THE BIOLOGICAL SIGNIFICANCE OF THE OLFACTORY SENSE

In the lower animals, just as in mankind and mammals, the sense of smell plays a part in the most varied activities of life. The most widespread use to which it is put is the finding of food. This is already very marked in Coelenterates. If we put a little meat juice into an aquarium containing sea-anemones, we may be sure that, in a short time, all the anemones will be most beautifully expanded. The turbellarian worms (planarians) also have

a very acute olfactory sense. If we wish to collect a number of these animals, it frequently suffices to place the body of a frog, cut up, in a running brook. All the planarians which are downstream from this place scent the bait, and creep upstream to it.

Gastropods also find their food with the help of their very acute olfactory sense. If we offer a juicy fruit or a lettuce leaf enclosed in a glass to a (Roman) vineyard snail (*Helix pomatia*), it takes no notice of it at all. From this it had been concluded previously (by Yung) that the animals were almost blind, but it only follows that they use their eyes for a different purpose, namely for the perception of the direction whence the light comes (compare article on SIGHT), while they find food by means of their olfactory sense. As soon as we put the fruit uncovered on the table, so that it can give out its scent unhindered, it is found very quickly.



FROM "TIERBAU AND TIERLEBEN" (TEUBNER)

FIG. 1.—ICHNEUMON-FLY

Depositing eggs in larva of pine-borer (after Doflein)

Very characteristic examples of the searching out of food with the aid of the olfactory sense are furnished by insects. Among the Lepidoptera the female usually lays her eggs on the leaves of plants, which are, later on, devoured by the caterpillar; there is no doubt but that in this unfailing, maternal instinct, she is directed by the olfactory sense. The sense of smell in ichneumon-flies is truly wonderful. As is well known, these insects lay their eggs in the larvae of other insects, which they find out even under the most difficult conditions. (*See* fig. 1.)

On the other hand, it is just among insects that we find, also, many examples of the seeking out of the female by the male by the aid of the olfactory sense. The most noted examples again occur among Lepidoptera. In silk-moths (Bombycidae), the great development of the olfactory sense is shown by the structure of the large, broad, feathery antennae. (*See* fig. 2.) Standfuss placed a female of the Emperor moth (*Saturnia pavonia*), which had just emerged from the cocoon, at his window, in the heart of the town, and, within 6½ hours, was able to catch 127 males, which had been attracted to her. These interesting experiments have since been repeated by numerous investigators. Mell marked a number of males of the large Chinese silk-moth (*Actias selene*), and released them at different points on a railway to seek out the female, which had been placed in a gauze cage on the veranda of his house. 40% found their way back from a distance of 4 kilometres, 26·6% from a distance of 11·6 kilometres. To human beings this olfactory power seems to border on the marvellous, the more so, in that we ourselves can perceive not the slightest odour from the female moth in question. The idea has been entertained, therefore, that these insects emit, perhaps, some kind of ray, but Forel showed that the males are attracted also to the place on which, a short time previously, a female had settled. This proves definitely that it has to do with a material scent.

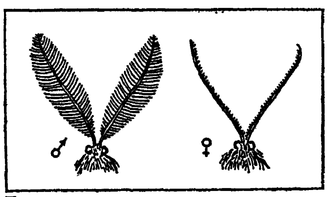


FIG. 2.—ANTENNAE OF THE SILK-MOTH (AGULIA TAU)

It is a remarkable thing that, so far, only a few instances are known of the lower animals detecting enemies by the aid of the sense of smell, and these occur in certain molluscs. We can surely induce the scallop (*Pecten*), to swim away if we bring its greatest enemy, the starfish, into its vicinity.

Among social insects the sense of smell is frequently of decisive significance in the social life of the members of a community. Certain ants (*Myrmica*) know their comrades definitely only through their sense of smell. Forel showed that they fall upon one another with the greatest fury if their olfactory organs, the antennae, are cut off. It has long been known that bees which enter a strange hive are immediately put to death, because the scent of a foreign hive clings to them. Bees possess, in addition, a peculiar scent-organ on the end of the abdomen, which can be protruded, and is often used by them as a means of communicating with each other. According to von Frisch, when a worker has discovered a rich supply of food in some place, she performs a peculiar dance, which causes the other bees to follow her. They are led to the food store by means of the scent trail.

THE LOCATION OF THE SENSE OF SMELL

The sense of smell is, usually, only very indefinitely located in invertebrates. In these animals, the sensory cells which react to chemical stimuli are clearly distributed over large areas of the skin. This applies particularly to Coelenterates, the more lowly of the worms, and the Echinoderms. In the last-mentioned animals, particularly in starfishes and ophiuroids, the chemical sense can be proved to be present in the thousands of ambulacral feet. Some ophiuroids bury themselves in the sand, leaving only the extremities of the arms projecting. The animals scent meat placed near them by means of the ambulacral feet which are situated in these parts.

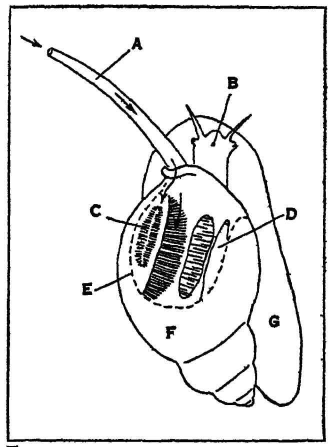

FIG. 3.—GILL-BREATHING GASTROPOD: (A) SIPHON, (B) HEAD, (C) OSPHRADIUM, (D) ANUS, (E) MARGIN OF MANTLE CAVITY, (F) GILLS, (G) FOOT

Even animals as highly organised as cuttlefishes show a wholly diffuse distribution of their chemical sense. (Giersberg.) It can be traced right into the extremities of the arms, the suckers being the most sensitive parts. On the other hand, the sensory pits situated behind the eyes, which, in former works, were described, without hesitation, as olfactory organs, have nothing to do with the chemical sense.

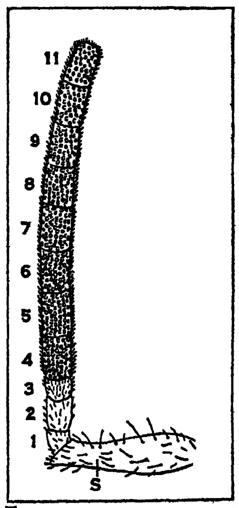

FIG. 4.—FEELER OF WORKER-BEE: JOINTS 4-11 BEAR THE OLFACTORY ORGANS (AFTER VON FRISCH)

The gill-breathing gastropods have, near the gills, an "osphradium," an oval thickened patch of epithelium, having many transverse folds (fig. 3). In some gastropods it has been proved experimentally that the osphradium is used in searching out food (Copeland). The animals used for the experiments, *Allectrion obsoleta* and *Busycon canaliculatus*, when crawling, wave their long respiratory siphon, by means of which they inhale water, rapidly to and fro. If, in this process, they inhale water which has an odour agreeable to them, they immediately swerve from their path, and are able to find the piece of food whence it emanates. This behaviour does not take place if the osphradium is removed by an operation. *Nassa reticulata*, which is common in European seas, buries itself almost completely in the sand in daytime, leaving only its long siphon projecting. If pieces of some bivalve are placed in the aquarium, in a very short time all the *Nassae* leave their retreats, and search for the food.

In insects, the feelers are the olfactory organs. Forel had proved already that, in these animals, the sense of scent is completely wanting after loss of the feelers. Later, v. Frisch in particular has occupied himself with this problem. He found that the olfactory organs of the bee are situated in the last eight joints of the feelers. Seven of these joints can be cut off without the bees' perception of odours being greatly damaged. When the eighth is cut off, however, all sense of smell is lost. In *Dytiscus* the olfactory sense is located in the end joint of the maxillary palp, as well as in the feelers.

The microscopic structure of the olfactory organs in the feelers

of insects is shown in fig. 5. The most important parts are the pore-plates, besides which the olfactory pegs and the pit-pegs are to be distinguished. The chitin is extraordinarily thin at the point where the sense organ is situated. A fine bundle of nerve fibres connects the organ immediately with the surface. The knowledge that these particular structures are the olfactory organs is not, by any means, drawn solely from their form. Von Frisch was able to prove definitely in the bee that the pore-plates are present only on those joints, the amputation of which is followed by the disappearance of the olfactory sense.

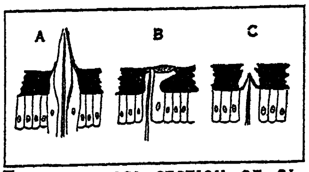

FIG. 5.—CROSS SECTION OF OLFACTORY ORGANS ON FEELERS OF INSECTS: (A) OLFACTORY PEG, (B) PORE-PLATE, (C) PIT-PEG (AFTER VON FRISCH)

In the higher Crustacea the chemo-receptors are situated on the outer ramus of the 1st antenna, on the mouth parts, and, indeed, also in the mouth cavity. On the antennae they take the form of olfactory hairs or olfactory pegs. These are very fine cylindrical structures, which are traversed, just as are the olfactory pegs of insects, by a bundle of the finest fibres, which appear to be extensions of the more deeply seated sensory cells.

In *Crangon* the 1st antennae occupy a particularly favourable position. When the animal is buried in the sand, they alone project from it, and thus to them falls the task of scenting possible prey. For this reason normal animals react to meat juice very much quicker than those which have no antennae. On the other hand, it can be shown that the antennae are not more sensitive than the more concealed sensory cells of the mouth parts, indeed, in certain respects, the antennae appear to be of even less importance. Stimulation of the antennae only never causes the typical food reaction, in which the crustaceans leave their hiding places, and seek the meat; to cause this, it is necessary for the mouth parts also to be stimulated.

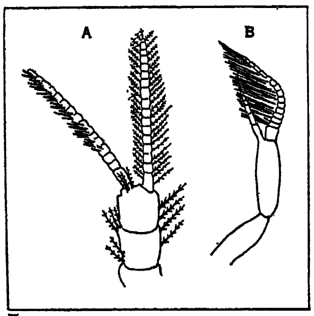

FIG. 6.—OLFACTORY ORGANS OF CRUSTACEA; 1ST ANTENNA OF (A) CRANGON (AFTER SPIEGEL), (B) UROLYCHUS NITIDUS (AFTER MARCUS)

The olfactory organ of the blood-sucking ticks (*Ixodes*) is in a particularly remarkable position. It is situated on the tibiae of the fore-legs, and is usually called "Haller's organ." Ticks, however, use their fore-legs, not for running, but as feelers; they elevate them and stretch them out in front of them. The olfactory organ, naturally, primarily aids the insect in finding its host. Such a faculty is particularly necessary to such creatures as the pigeon ticks (*Argas reflexus*) which, by day, hide away in some part of the dove-cote, and attack their hosts only by night. If the front legs are amputated, they lose all sensitiveness to chemical stimuli. (Hindle and Merriman.) They will then suck their fill of any warm liquid which may be offered to them in a suitable manner.

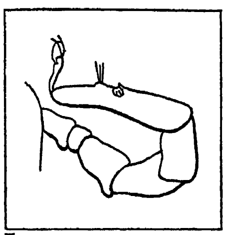

FIG. 7.—FRONT LEG OF THE TICK (IXODES RICINUS)

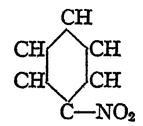
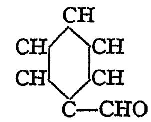
THE PHYSIOLOGY OF THE OLFACTORY SENSE

On the physiology of the olfactory sense in invertebrates, we are directed chiefly by the works of von Frisch, which deal with the olfactory sense of bees. He trained the bees to a particular odour, and, by this means, was able to establish the fact that they distinguish oil of orange-peel with certainty from 43 other ethereal oils. It may be concluded from this that, in nature, they are largely directed by the scent of the honey-bearing flowers. The most remarkable point is the extraordinary similarity shown by the olfactory sense of the bee to that of man. Substances which smell alike to man and are confused by him one with another, bees, in general, also are unable to distinguish.

We must conclude from this that the similarity or difference of the odours is conditioned by the particular character of the odorous molecule. According to Henning's hypothesis the quality of an odour depends not so much on the chemical composition of the odorous molecule as on the intramolecular combination of the groups of atoms, and, therefore, for example, mankind and bees confuse nitrobenzol with oil of bitter almonds.



Nitrobenzol



Oil of bitter almonds

Para- and meta-cresolmethyl ether, which are alike in their chemical composition, have a different kind of atomic structure, and are clearly distinguished by both man and bees. On the basis of this hypothesis it may, perhaps, be possible later to give an exact classification of the odorous substances for the whole animal kingdom.

At present, we do know very little about the nature of the chemical substances to which the other invertebrates react. Spiegel showed that for the shrimp, *Crangon,* the water-soluble constituents of fish muscle have a far greater attraction than those which are ether-soluble, which to the human nose are much the stronger. Particularly remarkable is the surely established fact that *Crangon* can smell glycogen, although, to human beings, this substance has neither taste nor smell.

THE SENSE OF TASTE

Among invertebrates, as we have already mentioned, a separate sense of taste has been demonstrated only in insects. In these creatures, we find spatially distinct olfactory and gustatory organs, which respond to different stimuli. Up to the present time, the insects which have been most studied are the honey-bee and the water beetle, *Dytiscus* (Schaller). The organs of taste are situated in the mouth cavity itself, as well as on the maxillary and labial palps, but not, however, on the olfactory antennae.

In the sense of taste, also, a remarkable agreement between that of man and that of insects is to be observed. The substances appreciated by the sense of taste are substantially the same in the two widely differing organisms. Sugar exercises a strong attraction. According to Minnich, the admiral butterfly (*Pyrameis atlanta*) is about 256 times as sensitive to cane sugar as man. It is a striking fact that insects do not accept all the kinds of sugar which taste sweet to us. The honey-bee responds only to cane sugar, the analysis products of which are d-glucose and d-fructose, as well as maltose.

Other sweet substances such as mannose, galactose or mannite and glycocoll are declined. In the same way, the bee-keeper has long known that bees will not take saccharine. Salt, bitter and sour substances, as well as lyes, always repel them; this is known to apply also to those animals which are without a separate sense of taste (Crustacea and gastropods).

It is of interest that the admiral butterfly, already mentioned several times, bears its organs of taste, not in the mouth, but on the tips of the feet (tarsi).

A marked reaction to tastes can be proved also in numerous animals which possess no separate gustatory sense. Bitter substances, in particular, are very generally declined (worms, gastropods, ascidians and holothurians). It is characteristic that the threshold of stimulation, that is to say, the minimum concentration to which the animal responds, is considerably lower in invertebrates than in fishes. Hanstroem connects this with the fact that the receivers of chemical stimuli in invertebrates are primary sensory cells, while those of vertebrates are of the type known as secondary sensory cells, in which the cell is in connection with the nerve only by contact.

The attraction exercised by sugar may be observed very frequently. Gastropods, in particular, are very greedy for sugar. It can be proved, however, that in these animals the sense-organs

by means of which they perceive it are not situated in the mouth itself, for when they are crawling on the surface of the water they will eat anything, impartially, which may be placed directly on the mouth. The gustatory cells are situated, apparently, on the anterior margin of the foot, which, in crawling, is the first part to come in contact with the substratum. Leeches, which have been studied by Loehner, also react very plainly to tastes. The experiments were so arranged that the animal first of all sucked blood which it found in a test-tube closed by an animal membrane. As soon as it had commenced to suck, the blood was replaced by some other liquid of the same degree of warmth. Pure water calls forth no reaction; if, however, too highly flavoured, concentrated substances are placed before it, the animal immediately leaves off. In the case of common salt this happened first when it was present in the proportion of 7%; with cane sugar when present in the proportion of 5%, with quinine sulphate at 1%. Salts and sugar are naturally contained in blood, but in a much lower degree of concentration. (W. v. Bud.)

SMELT (*Osmerus eperlanus*), the typical fish of the salmonoid family *Osmeridae,* which includes also the capelin (*Mallotus villosus*) and the candlefish (*Thaleichthys pacificus*). Except the curious *Plecoglossus* of the rivers of Japan, the *Osmeridae* are northern marine fishes, small and predacious. It breeds, unless land-locked, in salt or brackish water, and though it often enters rivers it does not ascend beyond tidal influence. Like other British salmonoids it spawns in winter. The smelt ranges from Scandinavia to the English Channel; it is a slender, silvery fish, with olive-green back. It grows to a length of 13 inches.

SMELTING: *see* Metallurgy.

SMERDIS (Pers. *Bardiya;* by Ctesias, *Pers.* 8, called *Tanyoxarces;* by Xenophon, *Cyrop.* viii. 7. 11, who takes the name from Ctesias, *Tanaoxares;* by Justin i. 9, *Mergis;* in Aeschylus, *Pers.* 774, *Mardos*), a Persian king. Smerdis was the younger son of Cyrus the Great who, according to Ctesias, on his deathbed appointed him governor of the eastern provinces. (*Cf.* Xen. *Cyrop.* viii. 7, 11.) Before Cambyses set out to Egypt, he secretly caused him to be murdered (Darius in the Behistun Inscr. i. 10), being afraid that he might attempt a rebellion during his absence. His death was not known to the people, and so in the spring of 522 a usurper pretended to be Smerdis and proclaimed himself king on a mountain near the Persian town Pishiyauvāda. Owing to the despotic rule of Cambyses and his long absence in Egypt, "the whole people, Persians, Medes and all the other nations," acknowledged the usurper, especially as he granted a remission of taxes for three years (Herod. iii. 68). Cambyses began to march against him, but seeing that his cause was hopeless, killed himself in the spring of 521 (but *see* further Cambyses). The real name of the usurper was, as Darius tells us, Gaumāta, a Magian priest from Media; this name has been preserved by Justin i. 9 (from Charon of Lampsacus?), but given to his brother (called by Herodotus Patizeithes), who is said to have been the real promoter of the intrigue; the true name of the usurper is here given as *Oropastes;* by Ctesias as *Sphendadates.*

The history of the false Smerdis is narrated by Herodotus and Ctesias according to official traditions; Cambyses before his death confessed to the murder of his brother, and in public explained the whole fraud. But, as Darius said, nobody had the courage to oppose the new king, who ruled for seven months over the whole empire. Contracts dating from his reign have been found in Babylonia, where his name is spelt *Barziya.* He transferred the seat of government to Media; and here in a castle in the district of Nisaya he was surprised and killed by Darius and his six associates in October 521. His death was annually celebrated in Persia by a feast called "the killing of the magian," at which no magian was allowed to show himself (Herod. iii. 79, Ctes. *Pers.* 15).

In the next year, another pseudo-Smerdis, named Vahyazdāta, rose against Darius in eastern Persia and met with great success. But he was finally defeated, taken prisoner and executed (Behistun Inscr. iii. 40 ff.; perhaps he is identical with the King Maraphis "the Maraphian," name of a Persian tribe, who occurs as successor in the list of Persian kings given by Aeschylus, *Pers.* 778).

See Darius (I.) and Persia, *Ancient History.* (Ed. M.)

SMETANA, FRIEDRICH (1824–1884), Czech composer and pianist, was born at Leitomischl in Bohemia on March 2, 1824. He studied under Proksch, at Prague, and later at Leipzig. On returning to Prague, he became Konzertmeister to the Emperor Ferdinand. In 1848 he married Katharina Kolar, pianist, and with her founded a music school at Prague. At the same time he met Liszt, who subsequently influenced him greatly, and with whom he afterwards stayed at Weimar. In 1856 Smetana went to Gothenburg as conductor of the Philharmonic Society. There he remained five years, when, owing to his wife's ill-health, he returned to Prague after a successful concert tour. The death of his wife at Dresden on their return caused Smetana to change his plans, and he went back to Sweden; but the opening of the Interim theatre in 1866, and the offer of its conductorship, brought him home again. In Sweden he had written *Hakon Jarl, Richard III.,* and *Wallenstein's Lager,* and had completed his opera *Die Brandenburger in Böhmen* (Jan. 5, 1866). In the same year he produced his best-known opera, *Die verkaufte Braut* ("The Bartered Bride"). The "grand prize" opera *Libuse,* was written for the opening of the National Theatre at Prague, on June 11, 1881. In 1874 Smetana lost his sense of hearing. To celebrate his sixtieth birthday a fête was arranged by the combined Bohemian musical societies; but on that day Smetana lost his reason and was removed to a lunatic asylum, where he died on May 12, 1884. Smetana was the founder of the Czech school of composers. He exercised a great influence over the younger men of his generation and is still held in great esteem. A great deal of his pianoforte music is interesting, the *Stammbuchblätter,* for example; while his symphonic poems in six parts, entitled *Mein Vaterland* (*Vlast*), and his beautiful string quartet, *Aus meinem Leben,* have made the tour of the civilized world.

Other operas are *Zwei Wittwen, Dalibor, Der Kuss, Das Geheimnis, Certova Stena,* and *Die Teufelsmauer.*

SMETHWICK (smĕth'ĭk), municipal, county and parliamentary borough, Staffs., England, 3 m. W. of Birmingham on the G.W. and L.M.S. railways. Pop. (1931) 84,354. There are large glass, chemical and machine works; nuts and bolts are made, and lighthouse fittings are a specialty. Adjoining Smethwick is the district of Soho, made famous by James Watt (*c.* 1770). The town of Smethwick is a modern growth about an ancient village, the name of which appears in Domesday. The borough was incorporated in 1899, became a county borough in 1907 and a parliamentary borough in 1918. It returns one member.

SMETONA, ANTANAS (1874–), Lithuanian statesman and journalist, was born on Aug. 10 1874, in the Ukmerge district, Lithuania, and made his law studies at St. Petersburg (Leningrad), graduating in 1902. Smetona edited the first Lithuanian daily, *Vilniaus Zinios* (Vilna news), and the democratic party organ, *Lietuvos Ukininkas.* In 1905 he was elected a member of the presidium of the Vilna (Wilno) diet, which proclaimed Lithuanian autonomy. On the convocation of the *tautos taryba,* or national council, during the German military occupation of the country, he was unanimously elected its president, and in the spring of 1919 first president of the newly-proclaimed independent state of Lithuania, a post which he held till the spring of 1920, when the constituent assembly was convened at Kaunas (Kovno). In 1921 Smetona served as chairman of the Lithuanian delegation at Riga during the negotiations on the settlement of the Latvian-Lithuanian boundary dispute. Early in 1923, when the insurrection broke out in the Memel territory against the German directorate, Smetona was requested by the Lithuanian Government to compose the trouble in co-operation with the Allied representatives. In the same year he joined the teaching staff of the newly established university as lecturer on philosophy. After the military *coup d'état* at Kovno on the night of Nov. 16–17, 1926, Smetona was elected (Dec. 17, 1926) by the new parliament to be president of the republic for a three years' term.

SMILES, SAMUEL (1812–1904), Scottish author, was born at Haddington, Scotland, on Dec. 23, 1812. He was the eldest of eleven children left, on their father's death, to be supported by their mother on slender means. To her spirit and example must

be attributed some of the enthusiasm for self-reliance and self-education, that was later embodied in Dr. Smiles's writings and led to their popularity and influence. He qualified in medicine at Edinburgh, but early abandoned medical practice for journalism. From 1838 till 1844 he edited the weekly *Leeds Times;* 1845 till 1854 he was secretary of the Leeds and Thirsk railway, and from 1854 till 1866 of the South Eastern railway. At Leeds he came in contact with George Stephenson, whose *Life* by him, published in 1857, passed through five editions in its first year and was the precursor of a long series of biographies of leaders in the world of industry. In 1859 had appeared his most successful book, *Self-Help,* which was translated into 17 languages. The book's success suggested others of similar purpose, like *Character* (1871), *Thrift* (1875), *Duty* (1880). Smiles died in Kensington in his ninety-second year, on the 16th of April 1904.

His *Autobiography* was edited (1905) by T. Mackay.

SMILLIE, JAMES DAVID (1833–1909), an American painter, born in New York city on Jan. 16, 1833. His father, James Smillie (1807–1885), a Scottish engraver, emigrated to New York in 1829, was elected to the National Academy of Design in 1851, did much, with his brother William Cumming (1813–1908), to develop the engraving of bank-notes, and was an excellent landscape engraver. The son studied with him and in the national academy of design; engraved on steel vignettes for bank-notes and some illustrations, notably F. O. C. Darley's pictures for Cooper's novels; was elected an associate of the National Academy in 1865—the year after he first began painting—and an academician in 1876; and was a founder (1866) of the American water-colour society and of the New York etching club. He died on Sept. 14, 1909.

SMILLIE (smĭ'lĭ), **ROBERT** (1859–), British politician, born March 17, 1859 in Belfast, of Scottish parents. He started work in a factory at 11 years of age, worked in a Clyde shipyard and later as a miner in the Lanarkshire pits. He was president of the Scottish Mine-workers' Association (1894–1918, and 1921–) and of the Miners' Federation of Great Britain (1912–21). Under his leadership the great strike of coal miners of 1912 was conducted and a national minimum wage secured. He was a member of the royal commission on mines set up in 1919 and presided over by Justice Sankey. He is (1928) a member of the general council of the Trades Union Congress. Though best known as a miners' leader, Smillie possessed strong internationalist sympathies, and was an ardent pacifist during the World War. After seven unsuccessful contests he was elected M.P. for Morpeth in 1923. In 1924 he published *My Life for Labour.*

SMITH, ADAM (1723–1790), British economist, the son of Adam Smith, comptroller of the customs at Kirkcaldy (Fifeshire), Scotland, and of Margaret Douglas, was born at Kirkcaldy on June 5, 1723, some months after the death of his father. When three years old, he was carried off by a party of "tinkers," but was soon rescued. Educated at Kirkcaldy under David Miller, he proceeded to the university of Glasgow in 1737, where he attended the lectures of Dr. Hutcheson; and in 1740 went to Balliol College, Oxford, with a Snell exhibition. He remained there until 1746 devoting himself to moral and political science and to ancient and modern languages, and labouring to improve his English style by translation, particularly from the French. Returning to Kirkcaldy, he resided there two years with his mother, continuing his studies, and in 1748 he removed to Edinburgh, where, under the patronage of Lord Kames, he gave lectures on rhetoric and belles-lettres. About this time began his acquaintance with David Hume, which afterwards ripened into friendship.

In 1751 he was elected professor of logic at Glasgow, and in 1752 he succeeded Thomas Craigie in the chair of moral philosophy. This position he had for nearly twelve years. In 1759 Smith published his *Theory of Moral Sentiments,* embodying the second portion of his university course, to which was added in the 2nd edition an appendix with the title, "Considerations concerning the first Formation of Languages." After the publication of this work his ethical doctrines occupied less space in his lectures, and a larger development was given to the subjects of jurisprudence and political economy. Stewart gives us to understand that he had, as early as 1752, adopted the liberal views of commercial policy which he afterwards preached; and this view is supported by the fact that such views were propounded in that year in the *Political Discourses* of Hume.

In 1762 the senatus academicus of Glasgow conferred on him the honorary degree of doctor of laws, but in 1763 on becoming tutor to the young duke of Buccleuch, he resigned his professorship, and went abroad with his pupil in February 1764. After spending eighteen months at Toulouse, they toured the south of France and visited Geneva, returning to Paris about Christmas of 1765. Smith frequented the society of Quesnay, Turgot, d'Alembert, Morellet, Helvétius, Marmontel and the duc de la Rochefoucauld, and was influenced by his contact with the members of the physiocratic school. Smith afterwards described Quesnay as a man "of the greatest modesty and simplicity," and declared his system of political economy to be, "with all its imperfections, the nearest approximation to truth that had yet been published on the principles of that science." Returning home in October 1766, Smith spent the next ten years at Kirkcaldy.

He was occupied on his great work, *Inquiry into the Nature and Causes of the Wealth of Nations* (1776), which there is some reason for believing he had begun at Toulouse. After its publication, and only a few months before his own death, Hume wrote to congratulate his friend—"*Euge! belle!* dear Mr. Smith, I am much pleased with your performance, and the perusal of it has taken me from a state of great anxiety. It was a work of so much expectation, by yourself, by your friends, and by the public, that I trembled for its appearance, but am now much relieved. Not but that the reading of it necessarily requires so much attention, and the public is disposed to give so little, that I shall still doubt for some time of its being at first very popular, but it has depth, and solidity, and acuteness, and is so much illustrated by curious facts that it must at last attract the public attention." Smith attended Hume during a part of his last illness, and soon after the death of the philosopher there was published, along with his autobiography, a letter from Smith to W. Strahan (Smith's publisher) in which he gave an account of the closing scenes of his friend's life and expressed warm admiration for his character.

The greater part of the two years which followed the publication of the *Wealth of Nations* Smith spent in London, enjoying the society of Gibbon, Burke, Reynolds and Topham Beauclerk, etc., but on being appointed commissioner of customs in Scotland, he went to live at Edinburgh with his mother and his cousin, Jane Douglas. Much of his income is believed to have been spent in secret charities, and he kept a simple table at which, "without the formality of an invitation, he was always happy to receive his friends." "His Sunday suppers," says M'Culloch, "were long celebrated at Edinburgh." One of his favourite places of resort in these years was a club of which Dr. Hutton, Dr. Black, Dr. Adam Ferguson, John Clerk the naval tactician, Robert Adam the architect, as well as Smith himself, were original members, and to which Dugald Stewart, Professor Playfair and other eminent men were afterwards admitted. Another source of enjoyment was his small but excellent library. In 1787 he was elected lord rector of the university of Glasgow, and in the same year he probably visited London. From the death of his mother in 1784, and that of Miss Douglas in 1788, his health declined, and after a painful illness he died on July 17, 1790.

In accordance with his wishes the majority of his manuscripts were destroyed. Of the pieces preserved by his desire the most valuable is his tract on the history of astronomy, which he himself described as a "fragment of a great work." Among the papers destroyed were probably, as Stewart suggests, the lectures on natural religion and jurisprudence which formed part of his course at Glasgow, and also the lectures on rhetoric which he delivered at Edinburgh in 1748. To the latter Hugh Blair seems to refer when, in his work on *Rhetoric and Belles-Lettres* (1783), he acknowledges his obligations to a manuscript treatise on rhetoric by Smith, part of which its author had shown to him many years before, and which he hoped that Smith would give to the public. Smith had promised at the end of his *Theory of Moral Sentiments* a treatise on jurisprudence from the historical point

of view.

As a moral philosopher Smith cannot be said to have won much acceptance for his fundamental doctrine, which is, that all our moral sentiments arise from sympathy, "which leads us to enter into the situations of other men and to partake with them in the passions which those situations have a tendency to excite."

It is on the *Wealth of Nations* that Smith's fame rests. But it must at once be said that it is contrary to fact to represent him, as some have done, as the creator of political economy. The subject of social wealth had always in some degree, and increasingly in recent times, engaged attention, and its study had even indisputably assumed a systematic character. From being an assemblage of fragmentary disquisitions on particular questions of national interest it had taken the form, notably in Turgot's *Réflexions*, of an organized body of doctrine. Smith took up the science when it was already considerably advanced; and it was this very circumstance which enabled him, by the production of a classical treatise, to render most of his predecessors obsolete.

Even those who do not fall into the error of making Smith the creator of the science often separate him too broadly from Quesnay and his followers, and represent the history of modern economics as consisting of the successive rise and reign of three doctrines—the mercantile, the physiocratic and the Smithian. The last two are, it is true, at variance in some even important respects, but if we regard them as historical forces, they must be considered as working towards identical ends. They both urged society towards the abolition of the previously prevailing industrial policy of European governments; and their arguments against that policy rested essentially on the same grounds.

There has been much discussion on the question—What is the scientific method followed by Smith in his great work? By some it is considered to have been purely deductive, a view which Buckle has perhaps carried to the greatest extreme. That the inductive spirit exercised no influence on Scottish philosophers is certainly not true. What may justly be said of Smith is that the deductive bent was not the predominant character of his mind, nor did his great excellence lie in the "dialectic skill" which Buckle ascribes to him. What strikes us most in his book is his wide and keen observation of social facts, and his perpetual tendency to dwell on these and elicit their significance, instead of drawing conclusions from abstract principles.

Some have represented Smith's work as of so loose a texture and so defective in arrangement that it may be justly described as consisting of a series of monographs; but this is an exaggeration. The book, it is true, is not framed on a rigid mould, nor is there any parade of systematic divisions and subdivisions. But, as a body of exposition, it has the real unity which results from a mode of thinking homogeneous throughout.

Rent, Wages and Profit.—Smith sets out from the thought that the annual labour of a nation is the source from which it derives its supply of the necessaries and conveniences of life. He does not contemplate labour as the only factor in production; but by emphasizing it at the outset he at once strikes the note of difference between himself on the one hand, and both the mercantilists and the physiocrats on the other. The improvement in the productiveness of labour depends largely on its division; and he proceeds accordingly to give his unrivalled exposition of that principle, of the grounds on which it rests, and of its greater applicability to manufactures than to agriculture, in consequence of which the latter relatively lags behind in the course of economic development. The origin of the division of labour he finds in the propensity of human nature "to truck, barter or exchange one thing for another." He shows that a certain accumulation of capital is a condition precedent to this division, and that the degree to which it can be carried is dependent on the extent of the market. When the division of labour has been established, each member of the society must have recourse to the others for the supply of most of his wants; a medium of exchange is thus found to be necessary and money comes into use. The exchange of goods against each other or against money gives rise to the notion of value.

This word has two meanings—that of utility, and that of purchasing power; the one may be called value in use, the other value in exchange. Merely mentioning the former, Smith goes on to study the latter, and endeavours to find a measure of value, and the forces regulating exchange value. He maintains that labour is the real measure of the exchangeable value of all commodities. "Equal quantities of labour at all times and places, are of equal value to the labourer." "Labour alone, therefore, never varying in its own value, is alone the ultimate and real standard by which the value of all commodities can at all times and places be estimated and compared. It is their real price; money is their nominal price only." Money, however, is in men's actual transactions the measure of value, as well as the vehicle of exchange; and the precious metals are best suited for this function, as varying little in their own value for periods of moderate length; for distant times, corn is a better standard of comparison. In relation to the earliest social stage, we need consider nothing but the amount of labour employed in the production of an article as determining its exchange value; but in more advanced periods price is complex, and consists in the most general case of three elements—wages, profit and rent. Wages are the reward of labour. Profit arises as soon as stock, being accumulated in the hands of one person, is employed by him in setting others to work, and supplying them with materials and subsistence, in order to make a gain by what they produce. Rent arises as soon as the land of a country has all become private property.

Smith then discusses the three elements of rent, wages and profits in detail. He goes on to point out that, as they are the elements of price, so they are the constituents of income; and the three great orders of every civilized society, from whose revenues that of every other order is ultimately derived, are the landlords, the labourers and the capitalists. The relation of the interests of these three classes to those of society at large is different. The interest of the landlord always coincides with the general interest: whatever promotes or obstructs the one has the same effect on the other. So does that of the labourer. But "the interest of the third order has not the same connection with the general interest of the society as that of the other two; . . . it is always in some respects different from and opposite to that of the public."

Capital.—The subject of the second book is "the nature, accumulation and improvement of stock." A man's whole stock consists of two portions—that which is reserved for his immediate consumption, and that which is employed so as to yield a revenue to its owner. This latter, which is his "capital," is divisible into the two classes of "fixed" and "circulating." The first is such as yields a profit without passing into other hands. The second consists of such goods, raised, manufactured or purchased, as are sold for a profit and replaced by other goods; this sort of capital is therefore constantly going from and returning to the hands of its owner. The whole capital of a society falls under the same two heads. Its fixed capital consists chiefly of (1) machines, (2) buildings which are the means of procuring a revenue, (3) agricultural improvements and (4) the acquired and useful abilities of all members of the society (since sometimes known as "personal capital"). Its circulating capital is also composed of four parts—(1) money, (2) provisions in the hands of the dealers, (3) materials and (4) completed work in the hands of the manufacturer or merchant. Next comes the distinction of the gross national revenue from the net—the first being the whole produce of the land and labour of a country, the second what remains after deducting the expense of maintaining the fixed capital of the country and that part of its circulating capital which consists of money.

Smith explains the gain to the community arising from the substitution of paper money for that composed of the precious metals; and here occurs the remarkable illustration in which the use of gold and silver money is compared to a highway on the ground, that of paper money to a wagon way through the air. In proceeding to consider the accumulation of capital, he is led to the distinction between productive and unproductive labour. A broad line of demarcation is drawn between the labour which results in commodities or increased value of commodities, and that which renders services: the former is productive, the latter unproductive. "Productive" is by no means equivalent to "useful"; the labours

of the magistrate, the soldier, the churchman, lawyer and physician, are, in Smith's sense, unproductive. Productive labourers alone are employed out of capital; unproductive labourers, as well as those who do not labour at all, are all maintained by revenue. In advancing industrial communities, the portion of annual produce set apart as capital bears an increasing proportion to that which is immediately destined to constitute a revenue, either as rent or as profit. What is annually saved is as regularly consumed as what is spent, but by a different set of persons, by productive labourers instead of idlers or unproductive labourers; and the former reproduce with a profit the value of their consumption. The only mode of increasing the annual produce of the land and labour is to increase either the number of productive labourers or the productive powers of those labourers. With regard to price paid for the use of capital Smith says: "In some countries the interest of money has been prohibited by law. But, as something can everywhere be made by the use of money, something ought everywhere to be paid for the use of it," and will in fact be paid for it; and the prohibition will only heighten the evil of usury by increasing the risk to the lender.

As to the different employments of capital, the quantity of productive labour put in motion by an equal amount varies extremely according as that amount is employed—(1) in the improvement of lands, mines or fisheries, (2) in manufactures, (3) in wholesale or (4) retail trade. In agriculture "Nature labours along with man," and not only the capital of the farmer is reproduced with his profits, but also the rent of the landlord. It is therefore the employment of a given capital which is most advantageous to society. Next in order come manufactures; then wholesale trade —first the home trade, secondly the foreign trade of consumption, last the carrying trade. All these employments of capital, however, are not only advantageous, but necessary, and will introduce themselves in the due degree if left to individual enterprise.

These first two books contain Smith's general economic scheme; and we have stated it as fully as was consistent with the brevity here necessary, because from this formulation of doctrine the English classical school set out, and round it the discussions of more modern times in different countries have in a great measure revolved.

The longest and most elaborate of the masterly historical sketches given by Smith occupies the third book; it is an account of the course followed by the nations of modern Europe in the successive development of the several forms of industry. It affords a curious example of the effect of doctrinal prepossessions in obscuring the results of historical inquiry. Whilst he correctly describes the European movement of industry, and explains it as arising out of adequate social causes, he yet, in accordance with the absolute principles which tainted his philosophy, protests against it as involving an entire inversion of the "natural order of things." First agriculture, then manufactures, lastly foreign commerce; any other order than this he considers "unnatural and retrograde."

Freedom of Trade.—The fourth book is principally devoted to the elaborate and exhaustive polemic against the mercantile system which has exercised a powerful influence on economic legislation. When protection is now advocated, it is commonly on different grounds from those which were in current use before the time of Smith. Though regarding the eventual establishment of free trade in England as unlikely, he is nevertheless in favour of it, but, believing in the necessity of adequate defence, he commends the navigation acts. Whilst objecting to the prevention of the export of wool, he proposes a tax on that export as somewhat less injurious to the interest of growers than the prohibition, whilst it would "afford a sufficient advantage" to the domestic over the foreign manufacturer. This is, perhaps, his most marked deviation from the rigour of principle. The wisdom of retaliation in order to procure the repeal of high duties or prohibitions imposed by foreign governments depends, he says, altogether on the likelihood of its success in effecting the object aimed at, but he does not conceal his contempt for the practice of such expedients. The restoration of freedom in any manufacture, when it has grown to considerable dimensions by means of high duties, should, he thinks, from motives of humanity, be brought about only by degrees and with circumspection—though the amount of evil which would be caused by the immediate abolition of the duties is, in his opinion, commonly exaggerated. The case of infant industries on which J. S. Mill justified protection, is referred to by Smith; but he is opposed to the admission of this exception for reasons which do not appear to be conclusive. He is perhaps scarcely consistent in approving the concession of temporary monopolies to joint-stock companies undertaking risky enterprises "of which the public is afterwards to reap the benefit."

He is less absolute in his doctrine of governmental non-interference when he comes to consider in his fifth book the "expenses of the sovereign or the commonwealth." He recognizes as coming within the functions of the state the erection and maintenance of those public institutions and public works which, though advantageous to the society, could not repay, and therefore must not be thrown upon, individuals or small groups of individuals. He remarks in a just historical spirit that the performance of these functions requires very different degrees of expense in the different periods of society. Besides the institutions and works intended for public defence and the administration of justice, and those required for facilitating the commerce of the society, he considers those necessary for promoting the instruction of the people. He thinks the public at large may with propriety not only facilitate and encourage, but even impose upon almost the whole body of the people, the acquisition in youth of the most essential elements of education. The expense of the institutions for religious instruction as well as for general education, he holds, may without injustice be defrayed out of the funds of the whole society, though he would apparently prefer that it should be met by the voluntary contributions of those who think they have occasion for such education or instruction.

To sum up, it may be said that the *Wealth of Nations* certainly operated powerfully through the harmony of its critical side with the tendencies of the half-century which followed its publication to the assertion of personal freedom and "natural rights." It discredited the economic policy of the past, and promoted the overthrow of institutions which had come down from earlier times, but were unsuited to modern society. As a theoretic treatment of social economy, and therefore as a guide to social reconstruction and practice in the future, it is provisional, not definitive. But when the study of its subject comes to be systematized on the basis of a general social philosophy more complete and durable than Smith's, no contributions to that final construction will be found so valuable as his.

The following may be referred to for biographical details: Dugald Stewart, *Biographical Memoir of Adam Smith,* originally read (1793) before the Royal Society of Edinburgh, and afterwards prefixed to Smith's *Essays on Philosophical Subjects;* J. A. Farrer, *Adam Smith* (1881); R. B. Haldane, *Life of Smith* (1887); and the very full and excellent *Life of Adam Smith* by John Rae (1895). Additional particulars are given in Brougham's *Men of Letters and Science,* Burton's *Life of Hume* and Alexander Carlyle's *Autobiography;* and some characteristic anecdotes of him will be found in *Memoirs of the Life and Works of Sir John Sinclair* (1837). For comments on his *Theory of Moral Sentiments, see,* besides Stewart, as cited above, Dr. T. Brown's *Philosophy of the Human Mind,* lects. 80 and 81; Sir J. Mackintosh's *Dissertation on the Progress of Ethical Philosophy;* and the art. ETHICS in the present work. On the *Wealth of Nations,* see the prefaces to M'Culloch's, Rogers's, Shield Nicholson's and Cannan's editions of that work; Rogers's *Historical Gleanings* (1869); the art. "Smith" in Coquelin and Guillaumin's *Dictionnaire de l'économie politique;* Bagehot's *Economic Studies* (1880); Cossa's *Guide to the Study of Political Economy* (Eng. trans., 1880), chap. v. and E. Cannan, *Theories of Production and Distribution 1776–1848* (1893). *See* also Professor Shield Nicholson's *Project of Empire* (1909), which is a critical study of the Economics of Imperialism, with special reference to the ideas of Adam Smith; and Professor W. J. Ashley's essay in *Compatriots, Club Lectures* (1905) on "Political Economy and the Tariff Problem." *See* also Professor W. J. Ashley's *Select Chapters and Passages from the*

"*Wealth of Nations*" (1895); C. W. Hasek, *The Introduction of Adam Smith's Doctrines into Germany* (N.Y. 1925).

SMITH, ALEXANDER (1830–1867), Scottish poet, son of a lace-designer, was born at Kilmarnock on Dec. 31, 1830. His parents being too poor to send him to college, he was placed in a linen factory to follow his father's trade of a pattern designer. His early poems appeared in the *Glasgow Citizen*. He became by appointment secretary to Edinburgh University in 1854. As a poet he was one of the leading representatives of what was called the "Spasmodic" School. Smith, P. J. Bailey and Sydney Dobell were satirized by W. E. Aytoun in 1854 in *Firmilian: a Spasmodic Tragedy*. In the same year Sydney Dobell came to Edinburgh, and an acquaintanceship at once sprang up between the two, which resulted in their collaboration in a book of *War Sonnets* (1855), inspired by the Crimean War. After publishing *City Poems* (1857) and *Edwin of Deira* (1861), a Northumbrian epic poem, Smith turned his attention to prose. He died on Jan. 5, 1867.

A memoir of Smith by P. P. Alexander was prefixed to a volume entitled *Last Leaves*.

SMITH, ALFRED EMANUEL (1873–), American politician, was born in New York city on Dec. 30, 1873, in the so-called Old Fourth ward under the Brooklyn Bridge. He was the elder of two children, a boy and a girl, of poor but respectable parents belonging to the city's Irish colony. The father, who had been a rather unsuccessful truckman, died in 1886, and his son's education at St. James's parochial school, near his home, was interrupted when he was in the 8th grade. Leaving school, however, did not depress him, as he had been little interested in his books.

Forced to help support his mother and sister, the boy attempted for a time to continue his father's trucking business. This did not pay and he abandoned it for employment with an oil supply house. Then he became a checker at the Fulton fish market, where he remained for seven years. Even as a small boy Smith had given indications of talent in elocution and amateur dramatics, and, despite long hours at work, he continued his interest in theatricals and at one time considered a stage career. He was a sociable youth with a gift for telling stories, for clog dancing and singing, and was exceedingly popular in the Fourth ward.

Smith's political career began in 1895 when the Tammany district leader made him an investigator in the city commissioner of jurors' office. This meant a salary of $800 a year. In the autumn of 1903 he was elected to the New York State Assembly on the Democratic ticket.

He went to Albany, the capital of New York State, with little or no formal education but with an alert mind and an intimate knowledge of the city district he represented. After a year or so of discouragement he began to make a name for himself and by 1911 was the Democratic leader. In 1913 he was speaker of the Assembly, an office secondary only to that of governor in power. He served continuously from 1904 to 1915. During the first ten years Smith gave small indication of the political independence he was to show as governor of New York. Industrious and intelligent, he was nevertheless a routine politician who obeyed the orders of Charles F. Murphy, the Tammany Hall "boss." Smith's defeat was constantly demanded by reform movements. By 1911, however, his viewpoint had been broadened through his appointment to a commission which investigated factory conditions. In 1915 he was sent as a delegate to the Constitutional Convention held at Albany to revise the State's fundamental law.

Tammany Hall rewarded Smith in 1915 for his long service as a poorly paid assemblyman by making him sheriff of New York county, a lucrative post because of the fee system, abolished after his term. In 1917 he was elected president of the board of aldermen in New York on the ticket with John F. Hylan. He resigned to run for governor in 1918. He was governor for four terms, the first man in the history of the State to have this honour. He showed extraordinary ability as a vote-getter. In 1918 he defeated Charles S. Whitman by 14,000 votes, when it was generally believed that he did not have a chance of winning. In 1920 he ran against Nathan L. Miller and was defeated in the Republican Presidential landslide, but polled 1,000,000 more votes in his State than did the Democratic presidential nominee. He became head of the United States Trucking Corporation, but in 1922 was drafted to run again. This time he defeated Miller, seeking re-election, by 1,397,633 to 1,011,725—the largest majority ever given a gubernatorial candidate in New York. In 1924 he defeated Theodore Roosevelt by 1,627,111 to 1,518,552. In 1926 he defeated Ogden L. Mills by 1,523,717 to 1,276,239. As governor, Smith fought for adequate housing, improved factory laws, proper care of the insane, child welfare and State parks. He effected a reorganization of the State Government on a consolidated and business-like basis. One of his first acts as governor was to call a special session of the legislature to ratify the Federal suffrage amendment. He repeatedly demonstrated his leadership by forcing Republican legislatures to accept his recommendations.

Smith was the first Roman Catholic to have received serious consideration as a presidential candidate. His religion, combined with his long record as an opponent of Prohibition, resulted in the deadlock at the Democratic National Convention of 1924. His nomination was opposed by the Protestant dry faction led by William G. McAdoo. On the 103rd ballot John W. Davis was nominated. Despite this defeat and despite criticism that he was unacquainted with national problems, Smith was the leading Democratic candidate for the nomination for president in 1928.

At the Houston Convention of the party on June 28th he was placed in nomination by Franklin D. Roosevelt (*q.v.*). The first ballot taken gave him the necessary two-thirds vote of the delegates. The victory was due to Smith's personal influence, his perfected organization and the determination of the Democrats to forget party differences and unite behind their strongest candidate as the only hope of challenging the Republican hold on the government. Though the western and southern Democratic delegates managed to bury the hatchet at the convention they could not persuade the people to do so in the election, and the opposition to Smith in the rural districts of closely contested States in the West and South doubtless defeated him in the election. Smith carried on an aggressive campaign, making several extended speaking tours into the South and West, but when the electoral votes were counted it was found he had lost 444 to 87. The popular vote was much closer, 21,943,328 to 15,430,718. (H. F. Pr.)

See *Up to Now*, An Autobiography (1929).

SMITH, ALFRED HOLLAND (1863–1924), American railway official, was born in Cleveland (O.), April 26, 1863. After having served in various capacities with the New York central railroads he was in 1890 appointed superintendent of the Kalamazoo division of the Lake Shore and Michigan southern railway. In 1902 he became general superintendent, in 1906 vice-president, and in 1914 president of the New York central system.

When the American railways were taken over by the U.S. Government on Dec. 27, 1917, he was appointed assistant director-general and worked out the form of central and regional administration under which the railways were managed during the 26 months of Government operation. He was re-elected president of the New York central lines in June 1919. He died in New York city March 8, 1924.

SMITH, ANDREW JACKSON (1815–1897), American soldier, was born in Bucks county, Pa., on April 28, 1815, and graduated at West Point in 1838. On the outbreak of the Civil War, he became a colonel of volunteer cavalry in the Federal army, rising early in 1862 to the rank of brigadier-general U.S. Volunteers. He took part in the first attack on Vicksburg and the capture of Arkansas Post, and the final Vicksburg campaign. Later, in the Red river expedition of Gen. N. P. Banks, he received the brevet of colonel for his services at the action of Pleasant hill. In May 1864 he became lieutenant-colonel U.S.A. and major-general U.S. Volunteers. He bore a conspicuous share in the crowning victory of Nashville (*q.v.*). Just before the close of the war he was breveted brigadier-general U.S. army for his services at the action of Tupelo, Miss., and major-general U.S.A. for Nashville. In 1869 he became postmaster of St. Louis, where he died on Jan. 30, 1897.

SMITH, CHARLES FERGUSON (1807–1862), American soldier, graduated from West Point academy in 1825, and a few years later became an instructor there, rising eventually to be commandant. As a battalion commander he distinguished himself in the Mexican War, at Palo Alto, Resaca, Monterrey and Churubusco. He commanded the Red river expedition of 1856, and served under Albert Sidney Johnston in Utah (1857–60). On the outbreak of the Civil War in 1861 he accepted a commission as brigadier-general of Union volunteers, and found himself under the command of Grant, who had been his pupil at West Point. This difficult situation was made easy by Smith's loyalty to his young chief, and the old soldier led his division of raw volunteers with success at Ft. Donelson.

His ripe experience, dignity, and unselfish character made him Grant's mainstay in the early days. He went up the Tennessee with the first expedition, but at Savannah (Tenn.), met with a serious accident. His senior brigadier led his division at the battle of Shiloh and he died on April 25, 1862. The early close of his career in high command deprived the Union army of one of its best leaders, and his absence was nowhere more felt than on the battlefield of Shiloh, where the Federals paid heavily for the inexperience of their generals. A month before his death he had been made major-general of volunteers.

SMITH, CHARLOTTE (1749–1806), English novelist and poet, eldest daughter of Nicholas Turner of Stoke House, Surrey, was born in London on May 4, 1749. She left school when she was twelve years old to enter society. She married in 1765 Benjamin Smith. Charlotte Smith's first publication was *Elegiac Sonnets and other Essays* (1784), dedicated by permission to William Hayley, and printed at her own expense. For some months Mrs. Smith (her husband was imprisoned for debt in 1782) and her family lived in a tumble-down château near Dieppe, where she produced a translation of *Manon Lescaut* (1785) and a *Romance of Real Life* (1786), borrowed from *Les Causes Célèbres.* On her return to England Mrs. Smith carried out a friendly separation between herself and her husband, and thenceforward devoted herself to novel writing. Her chief works are:—*Emmeline, or the Orphan of the Castle* (1788); *Celestina* (1792); *Desmond* (1792); *The Old Manor House* (1793); *The Young Philosopher* (1798); and *Conversations introducing Poetry* (1804). She died at Tilford, near Farnham, Surrey, on Oct. 28, 1806. She had twelve children, one of whom, Lionel (1778–1842), became lieutenant-general, and was governor of the Windward and Leeward Islands.

The best account of Mrs. Smith is by Sir Walter Scott, and is based on material supplied by her sister, Mrs. Dorset, with a detailed criticism of her work by Scott (*Misc. Prose Works,* 1841, i. 348–359). Charlotte Smith is best remembered by her charming poems for children, but *The Old Manor House* still repays reading.

SMITH, EDMUND KIRBY (1824–1893), Confederate general in the American Civil War, the son of Colonel Joseph Lee Smith (1776–1846), an American lawyer and soldier, who served in the War of 1812, was born at St. Augustine (Fla.), on May 16, 1824. He graduated at West Point in 1845, being assigned to the infantry. In the Mexican War he was breveted 1st lieutenant, and captain for gallantry. He was assistant professor of mathematics at West Point from 1849–52 and was later engaged in Indian warfare on the Texas frontier. In 1861 he attained the rank of major.

When Florida seceded he resigned his army commission and entered the Confederate service as a lieutenant-colonel. He was made a brigadier-general on June 17, 1861, and was wounded at the battle of Bull Run (*q.v.*). In command of the Confederate forces in the Cumberland gap region, he took part in Gen. Bragg's invasion of Kentucky (1862), and inflicted upon the Federal forces a severe defeat at Richmond (Ky.), on Aug. 30. From Feb. 1863 to the fall of the Confederacy he was in command of the trans-Mississippi department, and was successful in making this section of the Confederacy self-supporting. He instituted a regular system of blockade-running, and met and defeated the Red river expedition under Gen. N. P. Banks in 1864.

Kirby Smith and his troops surrendered in May 1865, being the last armed forces of the Confederate States to do so. After the war, he was president of the Atlantic and Pacific Telegraph company, president of the Western Military academy, chancellor of the University of Nashville, and from 1875 to his death professor of mathematics at the University of the South, Sewanee (Tenn.). He died at Sewanee on March 28, 1893.

SMITH, FRANCIS HOPKINSON (1838–1915), American author, artist and engineer, was born in Baltimore (Md.), Oct. 23, 1838, a descendant of Francis Hopkinson (*q.v.*). He became a contractor in New York city and did much work for the Federal Government, including the stone ice-breaker at Bridgeport (Conn.), the foundation for the Bartholdi statue of Liberty in New York harbour, the Race Rock lighthouse off New London (Conn.), and many life-saving stations. A charming record of his vacation wanderings is afforded by his various volumes of travel, illustrated by himself. Smith's novels and stories are especially felicitous in portraying the old South. Among them are *Colonel Carter of Cartersville* (1891); *Caleb West, Master Diver* (1898); *The Fortunes of Oliver Horn* (1902), which has reminiscences of his artist friends; *The Romance of an Old Fashioned Gentleman* (1907); *Peter* (1908); and *Kennedy Square* (1911). His *Novels, Stories and Sketches* appeared in the Beacon edition (1902, *seq.*). Smith died at New York city, April 8, 1915. Tribute and criticism are given by T. N. Page (*Scribner's Magazine,* Sept. 1915).

SMITH, GEORGE (1789–1846), British publisher, founder of the firm of Smith, Elder & Co., was born in Scotland in 1789. From Elgin, where he was apprenticed to a bookseller, he migrated to London, where he found employment first with Rivingtons, and afterwards with John Murray. In 1816 Smith and another Scot, Alexander Elder, began business at 158 Fenchurch Street as booksellers and stationers; and in 1819 they became publishers also. Here GEORGE SMITH (2) (1824–1901), the most famous member of the firm, was born on March 19, 1824; and in the same year the business was removed to 65 Cornhill. Smith removed the publishing business, when it came under his sole control, to 15 Waterloo Place. For over thirty years Smith was the friend and publisher of Ruskin, and it was with him that *Jane Eyre* found a publisher. The firm issued works by Darwin, Ruskin, Thackeray, Robert and Mrs. Browning, Wilkie Collins, Matthew Arnold, Miss Martineau, James Payn, Trollope and Mrs. Humphry Ward. In January 1860 the first of George Smith's three great undertakings was begun, the *Cornhill Magazine* being issued in that month under the editorship of Thackeray. The second venture was the founding in 1865 of the *Pall Mall Gazette.* (*See* NEWSPAPERS.) The third and most important was the publication of the *Dictionary of National Biography,* the first volume of which was issued in 1882; it was completed in 1901, in 66 volumes; and this monumental work, since carried on by successive supplements, was the crowning effort of a successful career. George Smith died at Byfleet, near Weybridge, on April 6, 1901.

See the memoir (1901) of George Smith (2) prefixed to vol. i. of the supplement to the *Dictionary of National Biography;* reminiscences contributed to the *Cornhill Magazine* (Nov. 1900–Feb. 1901) by George Smith; an article by Sir Leslie Stephen in the same magazine (May 1901); and the special number of the *Cornhill* in January 1910, published on its 50th anniversary.

SMITH, GEORGE ("George Smith of Coalville") (1831–1895), English philanthropist, was born near Tunstall, Staffs., on Feb. 16, 1831, the son of a bricklayer, and was self-educated. He became the manager of a brick and tile works at Coalville, where he had discovered valuable seams of clay, but was dismissed in 1872 because he advocated (and secured) legislation in the interest of the labourers and especially of the children in the industry. His representations also led to the passage of the Canal Boats bills (1878 and 1884) for the education of canal boat children and for the improvement of sanitary conditions on board. He was less successful in his efforts on behalf of gipsy children. Smith died at Crick, near Rugby, on June 21, 1895.

See E. Hodder, *George Smith of Coalville, the Story of an Enthusiast* (1896).

SMITH, GEORGE (1840–1876), English Assyriologist, was born on March 26, 1840, at Chelsea, London. Through the interest

of Sir Henry Rawlinson, Smith, who was a bank-note engraver by trade, was appointed assistant in the Assyriology department of the British Museum, and the earliest of his successes was the discovery of two inscriptions, one fixing the date of the total eclipse of the sun in the month Sivan in May 763 B.C., and the other the date of an invasion of Babylonia by the Elamites in 2280 B.C. In 1872 Smith achieved world-wide fame by his translation of the Chaldaean account of the Deluge. In the following January the *Daily Telegraph* arranged with Smith that he should go to Nineveh and carry out excavations with a view to finding the missing fragments of the Deluge story. This journey resulted in the discovery of the missing tablets, and of fragments which recorded the succession and duration of the Babylonian dynasties. In 1874 Smith again left England for Nineveh, this time at the expense of the Museum, and continued his excavations at Kouyunjik. In March 1876 the trustees of the British Museum despatched Smith once more to excavate the rest of Assur-banipal's library. He died at Aleppo Aug. 19, 1876.

SMITH, SIR GEORGE ADAM (1856–), Scottish divine, was born in Calcutta on Oct. 19, 1856, where his father, George Smith, C.I.E., was then principal of the Doveton college. He was educated at Edinburgh in the Royal high school, the university and New college. After studying at Tübingen and Leipzig and travelling in Egypt and Syria, he entered the ministry of the Free Church of Scotland and was appointed professor of Old Testament subjects in the Free Church College at Glasgow 1892. In 1909 he was appointed principal and vice-chancellor of the University of Aberdeen; in 1922 he was appointed Baird lecturer at Glasgow. In 1916 he was knighted. From 1916 to 1917 he was moderator of the General Assembly of the United Free Church of Scotland.

Among his works are *The Book of Isaiah* (2 vols. 1888–90); *The Book of the Twelve Prophets* (2 vols., 1896–97); *Historical Geography of the Holy Land* (1894); *Life of Henry Drummond* (1898); *Modern Criticism and the Preaching of the O. T.* (3rd Edn., 1902); *Jerusalem* (2 vols., 1908); *The Early Poetry of Israel* (1912); *Atlas of the Hist. Geog. of the Holy Land* (1915); *Jeremiah* (1923).

SMITH, GERRIT (1797–1874), American reformer and philanthropist, was born in Utica (N.Y.), on March 6, 1797. About 1828 he became an active worker in the cause of temperance, and in his home village, Peterboro, he built one of the first temperance hotels in the country. He became an abolitionist in 1835, after seeing an anti-slavery meeting at Utica broken up by a mob. In 1840 he took a leading part in the organization of the Liberty Party, and in 1848 and 1852 he was nominated for the Presidency by the remnant of this organization that had not been absorbed by the Free Soil Party. An "Industrial Congress" at Philadelphia also nominated him for the Presidency in 1848, and the "Land Reformers" in 1856. In 1840 and in 1858 he was a candidate for the governorship of New York on an anti-slavery platform. In 1853 he was elected to the U.S. House of Representatives as an independent. At the end of the first session he resigned his seat. After becoming an opponent of land monopoly, he gave numerous farms of 50 ac. each to indigent families, and also attempted to colonize tracts in northern New York with free negroes; but this experiment was a failure. Peterboro became a station on the "underground railroad"; and after 1850 Smith furnished money for the legal expenses of persons charged with infractions of the fugitive slave law. With John Brown, to whom he gave a farm in Essex county (N.Y.), he became very intimate, and from time to time supplied him with funds, though it seems without knowing that any of the money would be employed in an attempt to incite a slave insurrection. Under the excitement following the raid on Harper's Ferry, he became temporarily insane, and for several weeks was confined in an asylum in Utica. He favoured a vigorous prosecution of the Civil War, but at its close advocated a mild policy toward the late Confederate States, declaring that part of the guilt of slavery lay upon the North. He even became one of the securities for Jefferson Davis, thereby incurring the resentment of Northern Radical leaders. He died on Dec. 28, 1874, while on a visit to relatives in New York city.

See O. B. Frothingham, *Gerrit Smith: a Biography* (1879).

SMITH, GOLDWIN (1823–1910), British historian and publicist, was born at Reading on Aug. 13, 1823. He was educated at Eton and Magdalen college, Oxford, and became a fellow of University college. He was assistant secretary to the royal commission on the subject of university reform in 1850, and secretary to the commissioner appointed by the act of 1854. In 1868, when the question of reform at Oxford was again growing acute, he published a brilliant pamphlet, entitled *The Reorganization of the University of Oxford.* His aspiration that colonists and Americans should be attracted to Oxford has been realized by Mr. Rhodes's will. His principal historical writings—*The United Kingdom: a Political History* (1899), and *The United States: an Outline of Political History* (1893)—make no claim to original research, but are remarkable examples of terse and brilliant narrative.

The outbreak of the American Civil War proved a turning-point in his life. He warmly championed the cause of the North, and his pamphlets, especially one entitled *Does the Bible sanction American Slavery?* (1863), played a prominent part in converting English opinion. Visiting America on a lecture tour in 1864, he received an enthusiastic welcome, and was entertained at a public banquet in New York. In 1868 he threw up his career in England and settled in the United States, where he held the professorship of English and Constitutional History at Cornell University till 1871. In that year he removed to Toronto, where he edited the *Canadian Monthly,* and subsequently founded the *Week* and the *Bystander.*

He did not, however, cease to take an active interest in English politics. He stated that "if he ever had a political leader, his leader was John Bright, not Mr. Gladstone." Speaking in 1886, he referred to his "standing by the side of John Bright against the dismemberment of the great Anglo-Saxon community of the West, as I now stand against the dismemberment of the great Anglo-Saxon community of the East." These words form the key to his views of the future of the British Empire. He always maintained that Canada, separated by great barriers, running north and south, into four zones, each having unimpeded communication with the adjoining portions of the United States, was destined by its natural configuration to enter into a commercial union with them, which would result in her breaking away from the British empire, and in the union of the Anglo-Saxons of the American continent into one great nation. These views are most fully stated in his *Canada and the Canadian Question* (1891).

Goldwin Smith died at his residence, The Grange, Toronto, on June 7, 1910.

See Arnold Haultain, *Goldwin Smith, his Life and Opinions* (1913), which includes Smith's journal during his first visit to America in 1864.

SMITH, HENRY BOYNTON (1815–1877), American theologian, was born in Portland (Me.) on Nov. 21, 1815. He graduated at Bowdoin college in 1834; studied theology at Andover, where his health failed, at Bangor, and after a year (1836–37) as librarian and tutor in Greek at Bowdoin, in Paris, Halle and Berlin. He returned to America in 1840, was temporary instructor for a few months at Bowdoin, and in 1842 became pastor of the Congregational church of West Amesbury (now Merrimac, Mass.) where for several terms he combined with his church duties teaching at the Andover theological seminary. In 1847–50 he was professor of moral philosophy and metaphysics at Amherst; in 1850–54, Washburn professor of church history; and in 1854–74, Roosevelt professor of systematic theology, at Union theological seminary. He died in New York city Feb. 7, 1877. A leader of the "new school" Presbyterians, he always made it clear that his ideal philosophy was Christocentric.

From notes of his lectures, W. S. Karr prepared several volumes of Dr. Smith's theological writings, including *Introduction to Christian Theology* (1883) and *System of Christian Theology* (1884). Besides writing encyclopaedia and magazine articles, Dr. Smith was editor of the *American Theological Review. See* biographies by his wife (1881) and by L. F. Stearns (1892).

SMITH, SIR HENRY GEORGE WAKELYN, BART. (1787–1860), British general, son of John Smith, surgeon, of Whittlesey, Cambridgeshire, was born at that place on June 28, 1787. Harry Smith (as he consistently preferred to be called throughout his life) was educated privately and entered the army

in 1805. His first active service was in South America in 1806, and he subsequently served through the Peninsular War from the concentration at Salamanca in Nov. 1808 to the battle of Toulouse on April 10, 1814. He married in 1812 a young Spanish girl, Juana Maria de Los Dolores de Leon, who remained with him throughout the rest of the war, accompanying the baggage train, sleeping in the open on the field of battle, riding freely among the troops, and sharing all the privations of campaigning. "Juanita" was idolized by the soldiers. At the close of the war Harry Smith volunteered for service in the United States, where he was present at the battle of Bladensburg (Aug. 24, 1814), and witnessed the burning of the capitol at Washington, which, as he said, "horrified us, coming fresh from the duke's humane warfare in the south of France." Returning to Europe he was brigade-major at Waterloo; and in 1828 was ordered to the Cape of Good Hope, where he commanded a division in the Kaffir War of 1834–36. In 1835 he accomplished the feat of riding from Cape Town to Grahamstown, a distance of 600 m., in less than six days; and was appointed governor of the new province of Queen Adelaide, where he gained unbounded influence over the native tribes. But though supported by Sir Benjamin D'Urban, the high commissioner, the ministry in London reversed his policy and—to quote Smith's own words—"directed the province of Queen Adelaide to be restored to barbarism." Smith himself was removed from his command, his departure being deplored alike by the Kaffirs and the Dutch; and numbers of the latter, largely in consequence of this policy of Lord Glenelg, began the migration to the interior known as "the great trek."

Harry Smith was now appointed deputy-adjutant-general of the forces in India, where he took part in the Gwalior campaign of 1843 (for which he received a K.C.B.) and the Sikh War of 1845–46. He was in command of a division under Sir Hugh Gough at the battles of Moodkee and Ferozeshah, where he conspicuously distinguished himself, but was insufficiently supported by the commander-in-chief. After the second of these actions Smith was appointed to an independent command, and on Jan. 28, 1846, he inflicted a crushing defeat on the Sikhs at Aliwal on the Sutlej. At Sobraon on Feb. 10 he again commanded a division under Gough. For the great victory of Aliwal he was awarded the thanks of parliament, and was created a baronet. In 1847 he returned to South Africa as governor of Cape Colony and high commissioner, to grapple with the difficulties he had foreseen 11 years before (*see* CAPE COLONY: *History*). He took command of an expedition to deal with the disaffected Boers in the Orange River Sovereignty, and fought the action of Boomplaats on Aug. 29, 1848. In Dec. 1850 war broke out with the Kaffirs; Smith was insufficiently supplied with troops from England; and Lord Grey recalled him in 1852 before the Kaffirs had been completely subdued. He protested strongly against the abandonment of the Orange River Sovereignty to the Boers, which was carried out two years after his departure, and he actively furthered the granting of responsible government to Cape Colony. His Spanish wife was his constant companion in his second as in his earlier sojourn in South Africa, where her memory is recalled by the town of Ladysmith in Natal, as is that of her husband by Harrismith in the Orange Free State; while Aliwal North, founded in 1849 and named after his great Indian victory, further commemorates Smith. On his return to England he held a military appointment for some years, and died in London on Oct. 12, 1860. Juana, Lady Smith, survived till 1872.

See *Autobiography of Sir Harry Smith,* edited by G. C. Moore Smith (1901); R. S. Rait, *Life of Viscount Gough* (1903); Wilmot and Chase, *Annals of the Cape Colony* (1869); J. Noble, *South Africa* (1877); Theal's *History of South Africa,* vol. iv.

SMITH, HENRY JOHN STEPHEN (1826–1883), English mathematician, was born in Dublin on Nov. 2, 1826. When he was two years old his father died, and his mother left Ireland for England. After being privately educated he entered Rugby school in 1841, and Balliol College, Oxford, in 1844. He was elected a fellow of Balliol in 1850 and Savilian professor of geometry in 1861. He was elected F.R.S. in 1861. He served on various royal commissions, and from 1877 was the chairman of the managing body of the meteorological office. He died at Oxford on Feb. 9, 1883.

Smith published a few papers on geometry and then began a study of the existing work on the theory of numbers. The results of his researches are contained in his *Report on the Theory of Numbers,* which appeared in the British Association volumes from 1859 to 1865. His further original researches on the subject were communicated to the Royal Society in two memoirs upon "Systems of Linear Indeterminate Equations and Congruences" and upon the "Orders and Genera of Ternary Quadratic Forms" (*Phil. Trans.,* 1861 and 1867). He also established the principles on which the extension to the general case of *n* indeterminates depends, and obtained the general formulae. A brief abstract of his methods and results appeared in the *Proc. Roy. Soc.* for 1864 and 1868. As corollaries to the general formulae he adds the formulae relating to the representation of a number as a sum of five squares and also of seven squares. After 1864 he devoted himself chiefly to elliptic functions, and published papers in the *Proc. Lond. Math. Soc.* and elsewhere.

His *Collected Papers,* prefaced by several biographical notices, were edited by J. W. L. Glaisher (Oxford, 1894).

See the *Spectator* of Feb. 17, 1883, by Lord Justice Bowen; J. W. L. Glaisher's memoir in the *Monthly Notices of the Roy. Ast. Soc.* (vol. xliv., 1884).

SMITH, JAMES (1775–1839), and **HORACE** (1779–1849), authors of the *Rejected Addresses,* sons of a London solicitor, were born, the former on Feb. 10, 1775, and the latter on Dec. 31, 1779, both in London. The occasion of their happy *jeu d'esprit* was the rebuilding of Drury Lane theatre in 1812, after a fire in which it had been burnt down. The managers had offered a prize of £50 for an address to be recited at the reopening in October. The brothers Smith had the idea of making the most popular poets of the time figure as competitors and issuing a volume of unsuccessful addresses in parody of their various styles. They divided the task between them. James took Wordsworth, Southey, Coleridge and Crabbe, while Moore, Scott and Bowles were assigned to Horace. Both had a hand in Byron. Seven editions were called for within three months. *Rejected Addresses* is a classic in the literature of parody. The only other undertaking of the two brothers was *Horace in London* (1813). James Smith made another hit in writing *Country Cousins, A Trip to Paris, A Trip to America* and other lively skits for Charles Mathews who said he was "the only man who can write clever nonsense." James was reputed one of the best of talkers in an age when the art was studied, and it was remarked that he held his own without falling into the great error of wits—sarcasm. But in his old age the irreverent *Fraser's* put him in its gallery of living portraits as a gouty and elderly but painstaking joker. He died in London on Dec. 24, 1839.

After making a fortune as a stockbroker, Horace Smith wrote about a score of historical novels—*Brambletye House* (1826), *Tor Hill* (1826), *Reuben Apsley* (1827), *Zillah* (1828), *The New Forest* (1829), *Walter Colyton* (1830), etc. But he was more of an essayist than a story-teller. Three volumes of *Gaieties and Gravities,* published by him in 1826, contain many witty essays both in prose and in verse, but the only single piece that has taken a permanent place is the "Address to the Mummy in Belzoni's Exhibition." Shelley said of Horace: "Is it not odd that the only truly generous person I ever knew who had money enough to be generous with should be a stockbroker? He writes poetry and pastoral dramas and yet knows how to make money, and does make it, and is still generous." Horace Smith died at Tunbridge Wells on July 12, 1849.

See Beavan, *James and Horace Smith* (1899).

SMITH, JEREMIAH, JUNIOR (1870–), American lawyer and economist, was born at Dover, N.H., on Jan. 14, 1870. He graduated at Harvard university in 1892 and the Harvard law school in 1895. In 1895 he became secretary to Mr. Justice Gray of the U.S. Supreme Court, but in 1896 started the practice of law in Boston. He was a captain in the Quartermaster Corps A.E.F., in France in 1918. At the conclusion of hostilities he was appointed counsel to the treasury department in Europe and was associated in that capacity with the U.S. peace commission, acting also as

an adviser in financial matters. After the signature of the Treaty of Versailles he resumed practice in Boston. During 1924–26 he was commissioner general of the League of Nations in Hungary, being successful in stabilizing the currency and placing Hungarian finance on a sound basis. On the completion of his work, July, 1926, he returned to practice in Boston. He generously refused to accept any remuneration except his expenses; and the sum of approximately $60,000 thus saved was designated by the Government as a scholarship fund for sending Hungarian students to the United States.

SMITH, JOHN (1579–1631), the best known of the early settlers of Virginia, was born of excellent parentage at Willoughby, in Lincolnshire, England. He attended school but was an unwilling scholar, the call of the sea making itself heard in his consciousness. Hence when about 16 years of age he started on his adventures. These he pursued on land and sea, with a short interruption, for ten years, and to his lot fell a great number of unusual experiences and hairbreadth escapes.

It is unfortunate that our main source of information in reference to this period of Smith's life is the testimony of Smith himself, but where it has been possible to check his narrative it has been found substantially correct. Hence, argue his friends, why not accept his credibility as a whole? It is a notable fact that probably the closest student of Smith's works, Edward Arber, who in 1884 edited John Smith's works for the *English Scholar's Library,* gives his adherence unreservedly to this credibility. Professor Arber's hope, however, to establish Smith's reputation beyond dispute was vain, for very shortly after the appearance of Arber's edition Mr. Alexander Brown brought out his two books, *The First Republic in America* and *The Genesis of the United States,* in both of which Smith is heavily attacked. His animus against Smith arose from the fact that an exaltation of Smith appeared to him to carry with it a belittling of those engaged with Smith in the effort to establish a settlement at Jamestown, an effort engaged in by many leading Englishmen of the time, and of such importance as to merit disassociation from it of the idea that its success was at any time dependent on any one man.

When Smith finally returned to England in 1605, he was only twenty-six years of age, but his varied experiences had matured him early, and he had graduated from the ranks of the mere fighter and entered those of the pioneer and the colonizer. He threw himself with energy into colonization schemes. He embarked heart and soul in the London Company enterprise—first in securing the charter and then in securing colonists. Not only did he go himself, but he spent his money in getting others to go. It is a great compliment to Smith that the Council of the company in London chose him to be a member of the Council in Virginia. His selection shows that, though young, he was already a man of mark.

The colonists set out from England Dec. 19, 1606, and did not reach Virginia till April 26, 1607. When the box containing the names of the members of the Council was opened, and it was found to contain Smith's, he was not permitted to take his seat, being under arrest on a charge of conspiracy on the trip over. Later, however, he was cleared, and his principal accuser fined £200. He was admitted a member of the Council June 26, 1607.

The actual landing of the colonists at Jamestown was made on May 14, and on May 22 Captain Newport with a party including Captain Smith made explorations up the James River, reaching the site of Richmond at the falls. Beyond this he desired to march inland but was dissuaded by the Indian chief whose town was at the falls. Reaching Jamestown on the return on May 27, the party found that the Indians had the day before made an attack on the English when they were busy planting their corn, unsuspicious and unprepared. It was by means of the guns of the three ships lying close inshore that the enemy was forced to retire. In this fight was disclosed at least one of the advantages of Jamestown as the place of settlement, whatever points there may have been in its disfavour. The channel of the river there runs very close to the shore. Moreover, Jamestown Island was at that time a peninsula with a narrow, easily defensible neck, which was later, when Smith became president, protected by a block house.

On June 21 Captain Newport sailed away to England leaving 105 people at Jamestown with provisions for thirteen or fourteen weeks, under the command of the Council, with Edward Maria Wingfield as president, elected by the Council itself. Now a serious defect of organization soon become apparent. It was the Council that had the authority, not the president, who, however, presided at the deliberations of that body and had an additional vote in case of a tie. This form of government was absolutely bad. Too much time was taken up in wrangling in the Council, too much feeling was engendered between individual councillors. The situation—scanty provisions and sickness within the stockade among inexperienced and largely unsuitable colonists and, without, lurking and hostile savages—called for concentration and not dispersion of power. The strong hand was needed.

It fell to Smith's lot to trade with the Indians for provisions that were to keep the settlers alive till the return of Captain Newport. These difficult and dangerous trading expeditions he conducted with success. He always returned to Jamestown safe and with good supplies. Others, all too frequently, when these duties later devolved on them, either returned not at all or with empty baskets. Smith, no doubt, used all means in these expeditions—professions of friendship, cajolery, force, fraud, as well as fair trading. Several of these expeditions he made up the Chickahominy. On Dec. 10 he started out to discover the source of the Chickahominy, for it was thought that probably this source was in a ridge whose westerly flowing streams might have their outlet in the South Sea. It was on this trip that he was captured by the Indians and the best-known incident of his life occurred, namely, his rescue by Pocahontas, who when, according to the orders of Powhatan, her father, the great chief of a confederacy of Indians, he was led forth to execution in retaliation for the killing by him of an Indian in the fight in which he was captured, threw herself upon him and by her entreaties prevailed with her father to spare his life. This was the act of a kindhearted, simple little Indian maiden of twelve or thirteen years of age who had been entertained by Smith with stories and sights of marvels in the time he had been at her father's residence before the execution had been decided on. He was then adopted as a member of the tribe. Later he was permitted to return to Jamestown. He faced another danger, however, when he returned. His enemy Gabriel Archer, who had in his absence been made a member of the Council, promptly charged him under the Levitical law with the death of his companions. On this absurd charge he was actually tried and sentenced to be hanged. But the hanging was averted by the arrival of Captain Newport from England. When Newport with his "First Supply" arrived on the 9th of Jan. 1608, only 38 of the colonists remained of the original 105. When Newport again left the colony on April 10, he took with him Captains Wingfield and Archer. On April 20 arrived the "Phoenix," Captain Francis Nelson, the consort of Newport's ship of the "First Supply." Newport's ship and Nelson's ship had brought 120 colonists.

In the early summer of 1608 Smith set out on his famous exploration of the Chesapeake Bay and its tributaries. He explored both sides of the bay far up to its head and went up the Potomac River as far as the site of the present city of Washington and up the Rappahannock as far as the site of Fredericksburg. At one time he was so violently hurt by a stingray that he found it necessary to return to Jamestown to be treated by a surgeon. On this trip—or two trips—the party travelled three thousand miles in an open boat and met many adventures. One hardly knows which more to admire, the determined endurance of Smith and his men or the careful collection of data which went later into a narrative of the expedition and into a truly remarkable map.

When Smith returned from Stingray Point to get his surgeon, he found the colonists clamouring that Ratcliffe should be deposed from the presidency and Smith put in his place. This was accordingly done by the Council, but Smith asked his friend Scrivener to act for a time, and he resumed his explorations. He remained in Jamestown only from the 21st to the 24th of July. He returned from the second voyage on Sept. 7, 1608, and

three days later assumed the duties of president. His activities were incessant. In October came Captain Newport with the "Second Supply" consisting of seventy colonists. The population of Jamestown now numbered about 200, of whom, owing to improved conduct of affairs, no more than six or seven succumbed to disease before the arrival of the "Third Supply" the following year.

Newport's instructions from the Council in London, impatient for quick returns on the company's investment, were to find gold, discover the passage to the South Sea, search for Raleigh's missing colonists, crown Powhatan (in order to gain his favour), and to employ certain Poles and Dutchmen in making pitch, tar, glass, and soap-ashes. Smith was opposed to these objects, with a varying degree of intensity, as diverting energy which should be expended in making the colony self-supporting, first and foremost in the matter of the food supply. As for Powhatan, he knew that his favour and support were important, that trade with the Indians for supplies was essential, but he was opposed to the use of any great amount of flattery. It was only another case, however, in which a distant and imperfectly informed higher authority had to be obeyed by the able administrator on the spot. Hence Smith bent his energies toward carrying out the instructions. But when Newport returned to England, Smith sent, with his celebrated map already referred to, a letter to the Council setting forth plainly his views as to these instructions and as to all questions affecting the good of the colony. His letter is most important, stressing the necessity of sending over competent toilers to make the colony self-supporting.

During the winter Smith found it necessary to make several expeditions among the Indians to obtain corn to stave off famine and was always successful, though it was sometimes necessary for him to force the Indians to trade. He had many narrow escapes from disaster. His courage, his resourcefulness, and his knowledge of Indian character, however, brought him through. After his return from the last expedition, with what seemed to be enough corn to last for a long time, he compelled the lazy among the colonists to do their share of work, and many necessary things were done in Jamestown and the vicinity. Forty acres of corn were planted. Now the rats at Jamestown, however, ate up large quantities of the precious corn, and Smith experimented by sending parties off to live on oysters and fish, and even billeted some among the friendly Indians in the neighbourhood of Jamestown. Despite everything untoward that had happened and the shortage of food, Smith could feel in the spring and summer of 1609 that a solid foundation was being laid for the future wellbeing of the colony. His authority was now supreme because all the other members of the Council had died or returned to England.

On July 10, 1609, there arrived a ship under Captain Samuel Argall, to fish for sturgeon and to trade, and Captain Smith found it advisable to commandeer the provisions brought out, with the understanding, of course, that they would be paid for by the company. The ship brought out letters much less welcome to Smith than the supplies. In them he was much criticized for what the Council was pleased to think his harsh treatment of the Indians and for failure to send back to England more valuable cargoes. Smith bridled at the injustice. His letter to the Council sent by Newport the preceding November had had little effect. News was also brought that the London Company had obtained a new charter, providing for a reorganization of the plan of government of the colony. There was to be a governor-general, who was, or whose deputy was, to be in real control. Lord De la Warr was to be this governor; nine supply ships were coming over. Smith understood, of course, that this change in the government was wise, but he did not relish being set aside, and he honestly thought that he with his experience, especially with his knowledge of the Indians, was the best man that could be found for the position. And almost certainly he was correct, though it may be argued that Smith had by his overbearing and impatient manner with his equals—though not with his inferiors—in station made so many enemies among influential members of the company and colony that the time had come for a new man to be put in control, who would be sure, however, to profit by the experience of his predecessor.

Lord De la Warr did not at first intend to come to Virginia himself till much later but to remain in England and there give attention to its affairs. He was to be represented in Virginia by Sir Thomas Gates, lieutenant-governor. The "Sea Venture," carrying Sir Thomas Gates, lieutenant-governor, Sir George Somers, admiral, Sir Thomas Dale, high marshal, and Captain Christopher Newport, vice-admiral, was wrecked on one of the Bermuda Islands, and the arrival in Virginia of these high officials was much delayed. This vessel also carried instructions. The other ships were dispersed and much distressed by the same storm that wrecked the "Sea Venture," but four of them sailed up the James on August 11 and others came in later, all in a very dilapidated condition. These ships brought Ratcliffe, Martin and Archer, former members of the Council in Virginia. When these demanded that Smith give up his office, he refused, since neither the new governor nor the lieutenant-governor was at hand, nor had he been officially informed of the changes made. He chose, however, to recognize Martin as a member of the Council, though maintaining that the other two were not now legally members, and a few days before his year's term as president was to expire on Sept. 10, he named Martin as his successor, who immediately, however, resigned in favour of Smith. Smith now sent Martin to make a settlement among the Nansemond Indians and he himself went to inspect a settlement he had previously sent Captain West to make at the falls of the James. He found affairs going badly. When he was returning to Jamestown, he was dangerously burned by an explosion of gunpowder and his return to England was necessitated. With him went charges drawn up by his enemies in Virginia, which, however, were not pressed. But Smith was never employed again by the London Company. He had made too many enemies.

When he left, the harvest was newly gathered and the colony was otherwise in a sufficiently stable condition to ensure its steady growth if only a competent administrator had been in charge. We cannot, however, go further into the history of the colony except to say that things at once went to pieces. The winter of 1609–10 is known as the "starving time." The colony was only saved from extinction by the arrival in the spring of Sir Thomas Gates and a little later of Lord De la Warr.

Though Captain Smith saw no more service with the Virginia Company of London, he, when he recovered his health, carried on his work in the interests of colonization and in the establishment of fisheries. With two ships he made a fishing and exploring voyage in 1614, and, as he had done in the case of the Chesapeake Bay country, made a surprisingly accurate map of the New England coast from the Penobscot to Cape Cod. He called the country "New England" and he assigned the name "Plymouth" to the mainland opposite Cape Cod.

Smith gained the favour of Sir Ferdinando Gorges, one of the principal members of the Virginia Company of Bristol. Under his patronage he made in 1615 two attempts to reach New England for purposes of settlement, the first of which failed on account of stress of weather, and the next attempt was frustrated by his being captured by pirates. In 1617 he made another unsuccessful attempt. He had been given by the Virginia Company of Bristol the vain title of admiral of New England. In 1618 he endeavoured without success to enlist the support of Lord Bacon for his colonization plans. In 1619 he offered to pilot the Pilgrim Fathers to North Virginia, that is, New England, but the offer was not accepted. After this he was mainly engaged in producing pamphlets, books, and maps, the design of which was to excite an interest in the colonization of America and now especially that part of it he had named New England. He died in June, 1631. He was buried in St. Sepulchre's Church, London.

Smith's principal writings, the titles being given in modern spelling and abbreviated form and in the order of their publication, are as follows: *A True Relation* (1608); *A Map of Virginia* (1612); *A Description of New England* (1616); *New England's Trials* (1620); *The General History of Virginia, New England, and the Summer Isles* (1624); *An Accidence for All Young Seamen* (1626); the same work recast and enlarged and given the title

A Sea Grammar (1627); *The True Travels* (1630); *Advertisements for the Unexperienced Planters* (1631).

The best edition of Smith's works is that edited by Professor Edward Arber, and published in Birmingham, England, in 1884. In this are also printed most of the pamphlets of his contemporaries, including those unfriendly to Smith, so that the reader may be able to examine without trouble all the first-hand accounts of the settlement of Jamestown. The latest biography is by E. K. Chatterton. This was published in 1927 as one of the *Golden Hind Series,* which contains the biographies of the great Elizabethan seamen and explorers who gave lustre to that age. This book contains a full bibliography of Smith's own writings, and a very extensive list of the writings in reference to him. An engraving was made of Captain John Smith from life by Simon van der Pass, which has been reproduced many times. There is in the Virginia State Library a recently acquired portrait of an Englishman dressed in Turkish costume, which experts pronounce an original portrait of Captain Smith. (H. R. McI.)

SMITH, JOHN RAPHAEL (1752–1812), English painter and mezzotint engraver, son of Thomas Smith of Derby, landscape painter. He reproduced some forty of Reynolds' works, some of these plates ranking among the masterpieces of the art of mezzotint, and was appointed engraver to the prince of Wales. He had an extensive connection as a print-dealer and publisher, and would have been wealthy but for his dissipated habits. He was a boon companion of George Morland, whose figure-pieces he excellently mezzotinted. He died at Doncaster on March 2, 1812. As a mezzotint engraver Smith occupies the very highest rank. His prints are delicate, excellent in drawing and finely expressive of colour.

His small full-lengths in crayons and his portraits of Fox, Horne Tooke, Sir Francis Burdett and the group of the duke of Devonshire and family support his claims as a successful draughtsman and painter. Other paintings are the subject-pictures, the "Unsuspecting Maid," "Inattention," and the "Moralist."

SMITH, JOSEPH (1805–1844), founder of the Mormon religion, was born at Sharon, Vt. (U.S.A.), Dec. 23, 1805. In 1815 his parents moved to Palmyra, N.Y., on a hill near which Smith claimed to have unearthed in 1827, in answer to a vision, the golden plates of the *Book of Mormon.* With the aid of two optical instruments found with the plates Smith translated the characters they contained, which he said were "a revision of Egyptian hieroglyphics," and from behind a curtain dictated the matter to several scribes. In 1830 the first edition of the *Book of Mormon* was printed, and in the same year on April 6, some believers in his doctrines being found, Smith organized the "Church of Jesus Christ of Latter Day Saints." Subsequent revelations continued to be reported by Smith from time to time according to which the details of the church's organization and its laws were shaped. Smith directed the affairs of the church during its many trials and removals until he was killed, June 27, 1844, by a mob which attacked the jail at Carthage, Ill., in which he was confined. (*See* MORMONS.)

SMITH, RICHARD BAIRD (1818–1861), British engineer officer, was born on Dec. 31, 1818, was educated at Lasswade and Addiscombe, and joined the Madras Engineers in 1838. Being transferred to the Bengal Engineers, he served through the second Sikh war. In the Indian Mutiny, when Delhi was invested, he was appointed chief engineer in charge of the siege works, and prevented Wilson from relaxing his hold on Delhi until the arrival of John Nicholson with reinforcements from the Punjab, and of the siege train from Phillour. Nicholson then joined Baird Smith in compelling Wilson to make the assault, which proved successful, on Sept. 14. After the Mutiny he was made A.D.C. to Queen Victoria, and became secretary to the Government of India in the public works department. He died at sea on Dec. 31, 1861. He married a daughter of De Quincey, who long survived him.

See Colonel H. M. Vibart, *Richard Baird Smith* (1897).

SMITH, ROBERT (1689–1768), English mathematician, was born in 1689, probably at Lea near Gainsborough. After attending Leicester grammar school he entered Trinity College, Cambridge, in 1708, and becoming minor fellow in 1714, major fellow in 1715 and senior fellow in 1739, was chosen master in 1742, in succession to Richard Bentley. From 1716 to 1760 he was Plumian professor of astronomy, and he died at Cambridge on Feb. 2, 1768. He published *A Compleat System of Opticks* in 1738, which gained him the sobriquet of "Old Focus," and *Harmonics, or the Philosophy of Musical Sounds* in 1749. He was the founder of the Smith's prizes at Cambridge, leaving £3,500 South Sea stock to the university for the purpose.

See *Alumni Cantabrigenses* (Cambridge, 1927).

SMITH, ROBERT (1757–1842), an American statesman, was U.S. secretary of the navy, 1802–05, and attorney general, 1805–09, under Jefferson; also secretary of state, 1809–11, under Madison. In the last mentioned post he entered into an agreement with David M. Erskine, the British minister at Washington, which was promptly repudiated by George Canning, the British foreign secretary; and, when Canning sent the insolent Francis James Jackson to take Erskine's place at Washington, it became necessary for Secretary Smith to break off all relations with the British minister. Smith was much maligned by his enemies, the chief of whom was Albert Gallatin, who had been kept out of the office of secretary of state; and the reputation of Smith has subsequently suffered at the hands of historians. But a recent writer has pointed out that as a member of the Maryland legislature, and as secretary of the navy under Jefferson, Smith appeared eminently successful; and this writer has also shown that his work as secretary of state was of a high order, that Gallatin's charges against him (the mishandling of government funds) broke down completely, and that Gallatin, by threatening to resign as secretary of the treasury, prompted Madison to call for the resignation of Smith. After his retirement Smith reviewed his career as secretary of state in an *Address to the People of the United States* (June 1811). Thereafter he served in various positions in Maryland, and died on Nov. 26, 1842, the last survivor of the electoral college of 1789, which elected George Washington first president of the United States.

See Charles C. Tansill, "Robert Smith, Secretary of State," in Samuel Flagg Bemis (ed.), *The American Secretaries of State and Their Diplomacy,* iii. 151–200 (1927).

SMITH, SYDNEY (1771–1845), English writer and divine, son of Robert Smith, was born at Woodford, Essex, on June 3, 1771, the son of a wealthy and eccentric landowner. Sydney was the second of a family of four brothers and one sister, all remarkable for their talents. While two of the brothers, Robert Percy, known as "Bobus," afterwards advocate-general of Bengal, and Cecil, were sent to Eton, Sydney was sent with the youngest to Winchester, where he rose to be captain of the school. In 1789 he had become a scholar of New College, Oxford; he received a fellowship after two years' residence, took his degree in 1792 and proceeded M.A. in 1796. He was ordained priest at Oxford in 1796, and became a curate in the small village of Nether Avon, near Amesbury, in the midst of Salisbury Plain. The squire of the parish, Michael Hicks-Beach, engaged him after a time as tutor to his eldest son. It was arranged that they should proceed to the university of Weimar, but, before reaching their destination Germany was disturbed by war, and "in stress of politics," said Smith, "we put into Edinburgh." This was in 1798. While his pupil attended lectures, Smith was not idle. He studied moral philosophy under Dugald Stewart, and devoted much time to medicine and chemistry. He also preached in the Episcopal chapel, where his practical brilliant discourses attracted many hearers.

In 1800 he published his first book, *Six Sermons, preached in Charlotte Street Chapel, Edinburgh,* and in the same year, married, against the wishes of her friends, Catharine Amelia Pybus. They settled at No. 46 George Street, Edinburgh. Towards the end of his five years' residence in Edinburgh, in Jeffrey's flat in Buccleuch Place, Sydney Smith proposed the setting up of a review as an organ for young malcontents. "I was appointed editor," he says in the preface to the collection of his contributions, "and remained long enough in Edinburgh to edit the first number" (October 1802) of the *Edinburgh Review.* He continued to write for the *Review* for the next quarter of a century, and his brilliant articles were a main element in its success.

Life in London.—He left Edinburgh for good in 1803, when the education of his pupils was completed, and settled in London, where he was morning preacher at Berkeley Chapel, Mayfair, and "alternate evening preacher" at the Foundling Hospital. He lectured on moral philosophy at the Royal Institution for three seasons, from 1804 to 1806, when the London world crowded to Albemarle Street to hear him. With the brilliant reputation that Sydney Smith had acquired in the course of a few seasons in London, he would probably have obtained some good preferment had he been on the powerful side in politics. Sydney Smith's elder brother "Bobus" had married Caroline Vernon, aunt of the 3rd Lord Holland, and he was always a welcome visitor at Holland House. His Whig friends came into office for a short time in 1806, and presented him with the living of Foston-le-Clay in Yorkshire. He shrank from this banishment for a time, and discharged his parish duties through a curate; but Spencer Perceval's Residence Act was passed in 1808, and after trying in vain to negotiate an exchange, he moved his household to Yorkshire in 1809.

"Peter Plymley."—The Ministry of "All the Talents" was driven out of office in 1807 in favour of a "no popery" party, and in that year appeared the first instalment of Sydney Smith's most famous production, *Peter Plymley's Letters,* on the subject of Catholic emancipation, ridiculing the opposition of the country clergy. Its full title was *A Letter on the Subject of the Catholics to my brother Abraham who lives in the Country, by Peter Plymley.* Nine other letters followed before the end of 1808, when they appeared in collected form. Rumours of Peter Plymley's identity got abroad. Lord Holland wrote to him expressing his own opinion and Grenville's, that there had been nothing like it since the days of Swift (*Memoir,* i. 151). He also pointed out that Swift had lost a bishopric for his wittiest performance. Smith won the hearts of his Yorkshire parishioners as quickly as he had conquered a wider world. There had been no resident clergyman in his parish for 150 years; he had a farm of 300 acres to keep in order; a rectory had to be built. All these things were attended to beside his contributions to the *Edinburgh Review.* He continued to serve the cause of toleration by ardent speeches in favour of Catholic emancipation. "I defy Dr. Duigenan,"[1] he pleaded, addressing a meeting of clergy in 1823, "in the full vigour of his incapacity, in the strongest access of that Protestant epilepsy with which he was so often convulsed, to have added a single security to the security of that oath." At this time appeared one of his most vigorous and effective polemics, *A Letter to the Electors upon the Catholic Question* (1826).

Later Years.—Sydney Smith, after twenty years' service in Yorkshire, obtained preferment at last from a Tory minister, Lord Lyndhurst, who presented him with a prebend in Bristol cathedral in 1828, and two livings in the neighbourhood. From this time he discontinued writing for the *Edinburgh Review* on the ground that it was more becoming in a dignitary of the church to put his name to what he wrote. It was expected that when the Whigs came into power Sydney Smith would be made a bishop. But though he was not without warm friends at headquarters, the opposition was too strong for them. One of the first things that Lord Grey said on entering Downing Street was, "Now I shall be able to do something for Sydney Smith"; but he was not able to do more than appoint him in 1831 to a residentiary canonry at St. Paul's in exchange for the prebendal stall he held at Bristol. He was as eager a champion of parliamentary reform as he had been of Catholic emancipation, and one of his best fighting speeches was delivered at Taunton in October 1831 when he made his well-known comparison of the House of Lords, who had just thrown out the Reform Bill, with Mrs. Partington of Sidmouth, setting out with mop and pattens to stem the Atlantic in a storm.

On the death of his brother Courtenay he inherited £50,000, which put him out of the reach of poverty. He died at his house in Green Street, London, on Feb. 22, 1845, and was buried at Kensal Green.

[1]Patrick Duigenan, M.P. for the city of Armagh, a Protestant agitator.

Sydney Smith's other publications include: *Sermons* (2 vols., 1809); *The Ballot* (1839); *Works* (3 vols., 1839), including the *Peter Plymley* and the *Singleton Letters* and many articles from the *Edinburgh Review; A Fragment on the Irish Roman Catholic Church* (1845); *Sermons at St. Paul's . . .* (1846) and some other pamphlets and sermons. Lady Holland says (*Memoir,* i. 190) that her father left an unpublished ms., compiled from documentary evidence, to exhibit the history of English misrule in Ireland, but had hesitated to publish it. This was suppressed by his widow in deference to the opinion of Lord Macaulay.

See *A Memoir of the Reverend Sydney Smith by his daughter, Lady Holland, with a Selection from his Letters edited by Mrs.* [*Sarah*] *Austin* (2 vols. 1855); also *A Sketch of the Life and Times of . . . Sydney Smith* (1884) by Stuart J. Reid; a chapter on "Sydney Smith" in Lord Houghton's *Monographs Social and Personal* (1873); A. Chevrillon, *Sydney Smith et la renaissance des idées libérales en Angleterre au XIX^e siècle* (1894); and especially the monograph, with a full description of his writings, by G. W. E. Russell in *Sydney Smith* (English Men of Letters series, 1905). There are numerous references to Smith in contemporary correspondence and journals.

SMITH, THEOBALD (1859–), American pathologist, was born at Albany, N.Y., July 31, 1859. He graduated from Cornell (1881) and from the Albany medical college (1883). In 1884 he was appointed director of the pathological laboratory of the Bureau of Animal Industry, in the Dept. of Agriculture, at Washington, where for 11 years he investigated infectious animal diseases. At the same time he was professor of bacteriology at Columbian, later known as George Washington, university.

From 1895 to 1915 he was director of the pathological laboratory of the Massachusetts State board of health, and after 1896 was professor of comparative pathology at Harvard. In 1915 he was appointed director of the department of animal pathology of the Rockefeller institute of medical research, at Princeton, N.J.

His numerous scientific papers include *Investigations into the Nature, Causation, and Prevention of Texas or Southern Cattle Fever* (1893); *The Relation between Bovine and Human Tuberculosis* (1896–98); *The Immunizing Effect of Neutral Toxin-antitoxin Mixtures in Diphtheria* (1909); *Milk-borne Epidemics of Human Streptococci* (1915); *The Protective Value of Colostrum* (1922); *The Relation of Bovine Infectious Abortion to Malta Fever* (1925).

SMITH, SIR WILLIAM (1813–1893), English lexicographer, was born at Enfield in 1813 of Nonconformist parents. He taught himself classics while articled to a solicitor, entered University college, London, and took a post at University college school. He next turned his attention to lexicography. His first attempt was the *Dictionary of Greek and Roman Antiquities,* which appeared in 1842. The greater part of this was written by himself. In 1849 followed the *Dictionary of Greek and Roman Biography,* and the *Greek and Roman Geography* in 1857. In this work some of the leading scholars of the day were associated with him. In 1850 he published the first of the school dictionaries; and in 1853 he began the *Principia* series, which marked a distinct step in the school teaching of Greek and Latin. The most important, perhaps, of the books edited by William Smith were those that dealt with ecclesiastical subjects. These were the *Dictionary of the Bible* (1860–65); the *Dictionary of Christian Antiquities* (1875–80), undertaken in collaboration with Archdeacon Cheetham; and the *Dictionary of Christian Biography* (1877–87), jointly with Dr. Henry Wace. The *Atlas,* on which Sir George Grove collaborated, appeared in 1875. He edited Gibbon in 1854–55, and was editor of the *Quarterly Review* from 1867 to his death on Oct. 7, 1893. He was knighted in 1892.

SMITH, WILLIAM (*fl.* 1596), English sonneteer. He published in 1596 a sonnet sequence entitled *Chloris, or the Complaint of the passionate despised Shepheard.* He was a disciple of Spenser, to whom the two first sonnets and the last are addressed. He signed his name W. Smith, and has sometimes been confused with the playwright Wentworth Smith, who collaborated with John Day, William Haughton and others (1601–1603).

SMITH, WILLIAM (1769–1839), English geologist, called "the Father of English geology," and known among his acquaintances as "Strata Smith," was born at Churchill in Oxfordshire on March 23, 1769. At 18 he became assistant to Edward Webb, surveyor, of Stow-on-the-Wold, and traversed the Oolitic lands of Oxfordshire and Gloucestershire, the Lias clays and red marls

of Warwickshire and other districts, studying their varieties of strata and soils. In 1791 his observations at Stowey and High Littleton in Somersetshire first impressed him with the regularity of the strata. In 1793 he executed the surveys and levellings for the line of the Somerset coal canal, in the course of which he confirmed his supposition, that the strata above the coal were not horizontal, but inclined in one direction—to the east—so as to terminate successively at the surface.

On being appointed engineer to the canal in 1794 he made a tour with regard to inland navigation. He carefully examined the geological structure of England, and corroborated his generalization of a settled order of succession in the strata. In 1794 he coloured his first geological map—that of the vicinity of Bath—showing the ranges of the different strata across England.

In 1799 Smith dictated his first table of British Strata, now in the possession of the Geological society of London. It was headed *Order of the Strata, and their imbedded Organic Remains, in the neighbourhood of Bath; examined and proved prior to 1799*. In 1813 Joseph Townsend published, with acknowledgment, much information on the English strata communicated by William Smith, in a work entitled *The Character of Moses established for veracity as an historian, recording events from the Creation to the Deluge.* Meanwhile Smith was completing and arranging the data for his large *Geological Map of England and Wales, with part of Scotland* (15 sheets, 1815). The map was reduced to smaller form in 1819; and from this date to 1822 21 separate county geological maps and several sheets of sections were published in successive years, constituting a *Geological Atlas of England and Wales.*

Smith's collection of fossils was purchased in 1816–18 by the British Museum. In 1817 a portion of the descriptive catalogue, *Stratigraphical System of Organized Fossils,* was published. In 1816 he had commenced the publication of *Strata Identified by Organized Fossils,* with figures printed on paper to correspond in some degree with the natural hue of the strata. In this work (of which only four parts were published, 1816–19) is exemplified the principle he established of the identification of strata by their included organic remains. In 1831 the Geological society of London conferred on Smith the first Wollaston medal; and from the government he received a life-pension of £100 per annum. The last years of his life were spent at Hackness (of which he made a good geological map), near Scarborough, and in the latter town. He died at Northampton on Aug. 28, 1839.

His *Memoirs,* edited by his nephew, John Phillips, appeared in 1844.

SMITH, WILLIAM FARRAR (1824–1903), American general, was born at St. Albans, Vt., on Feb. 17, 1824, and graduated from West Point in 1845, being assigned to the engineer branch of the army. In Aug. 1861 he became brigadier-general of volunteers, and in July 1862 he received promotion to the rank of major-general, U.S. Volunteers. Smith led with conspicuous valour at Antietam and later was placed at the head of the VI. Corps of the Army of the Potomac, which he led at the disastrous battle of Fredericksburg (*q.v.*). The recriminations which followed led to a general order in which Smith and several other senior officers of the army were dismissed and suspended by Gen. Burnside. As a brigadier-general Smith commanded troops in Pennsylvania during the critical days of the Gettysburg campaign. Later, in 1863, as chief engineer of the Army of the Cumberland, he conducted the engineer operations which reopened the "cracker-line" from Chattanooga (*q.v.*) to the base of supplies. For the Virginian campaign of 1864 Smith was specially assigned by Grant to command the XVIII. Corps, Army of the James, and he took part in the battle of Cold Harbor and the first operations against Petersburg, after which, while absent on leave, he was suddenly deprived of his command by Grant. He resigned from the Volunteers in 1865 and from the U.S. Army in 1867. After 1881 he was engaged in civil engineering work. He died at Philadelphia on Feb. 28, 1903.

SMITH, WILLIAM HENRY (1825–1891), English man of business and statesman, was born in London on June 24, 1825. His father was the founder of the distributing firm of W. H. Smith & Son, in the Strand, and at an early age he became a partner and devoted himself to the business. In 1865 he contested Westminster in the Conservative interest against John Stuart Mill. He failed, but he won the seat in 1868. He was secretary to the treasury (1874), first lord of the admiralty (1877), secretary for war (1885), chief secretary for Ireland (1885), secretary for war (1886), and in the end of that year first lord of the treasury and leader of the House of Commons. He was no orator, and made no pretence to genius, but his success in these high offices was complete, and was due to the universal respect which was gained by his patience, good temper, zeal for the public service, and thorough kindness of heart. He died at Walmer Castle (which he occupied as Warden of the Cinque Ports) on Oct. 6, 1891. In recognition of his services a peerage in her own right was conferred on his widow, with the title of Viscountess Hambleden.

SMITH, WILLIAM ROBERTSON (1846–1894), Scottish philologist, physicist, archaeologist, Biblical critic, and editor, from 1881, of the 9th edition of this *Encyclopædia,* was born on Nov. 8, 1846, at Keig in Aberdeenshire, where his father was Free Church minister. He was educated at home and at Aberdeen University, where he won, among other honours, the Ferguson mathematical scholarship. In 1866 he entered the Free Church college at Edinburgh as a student of theology. During two summer sessions he studied philosophy and theology at Bonn and Göttingen. From 1868 to 1870 he acted as assistant to the professor of natural philosophy in Edinburgh University. During this period he produced much original work in the experimental and mathematical treatment of electricity. In 1870 he was appointed and ordained to the office of professor of Oriental languages and Old Testament exegesis at the Free Church college, Aberdeen. He was the pupil and personal friend of many leaders of the higher criticism in Germany, and from the first he advocated views which, though now widely accepted, were then regarded with apprehension. The articles on Biblical subjects which he contributed to the 9th edition of the *Encyclopædia Britannica* distressed and alarmed the authorities of the Free Church. In 1876 a committee of the General Assembly of that Church reported on them so adversely that Smith demanded a formal trial, in the course of which he defended himself with consummate ability and eloquence. The indictment dropped, but a vote of want of confidence was passed, and in 1881 Smith was removed from his chair. At the end of the trial he was probably the most popular man in Scotland. Marks of sympathy were showered on him from all sides.

In 1875 he was appointed one of the Old Testament revisers; in 1880–1882 he delivered by invitation, to very large audiences in Edinburgh and Glasgow, two courses of lectures on the criticism of the Old Testament, which he afterwards published (*The Old Testament in the Jewish Church,* first edition 1881, second edition 1892, and *The Prophets of Israel,* 1882, which also passed through two editions); and soon after his dismissal from his chair he joined Professor Baynes in the editorship of the *Encyclopædia Britannica,* and after Professor Baynes's death remained in supreme editorial control till the work was completed. His versatility, firmness combined with tact, width of view, and painstaking struggle for accuracy were largely responsible for the maintenance of its high standard. But he did not let his other duties interfere with his Semitic studies. He visited Arabia, Egypt, Syria, Palestine, Tunis and southern Spain, and had an intimate knowledge of, and personal acquaintance with, not only the literature, but the life of the East. His early friendship with J. F. McLennan, that most original student of primitive marriage, had a great influence on Smith's studies, and his attention was always strongly attracted to the comparative study of primitive customs and their meaning. His chief contributions to this branch of learning were his article SACRIFICE in the *Encyclopædia Britannica,* his *Kinship and Marriage in Early Arabia* (Cambridge, 1885), and above all his *Lectures on the Religion of the Semites* (1st edition 1889, 2nd edition 1894). His originality and grasp of mind enabled him to seize the essential among masses of details, and he had in a marked degree the power of carrying a subject farther than his predecessors.

In 1883 Robertson Smith was appointed Lord Almoner's Pro-

fessor of Arabic at Cambridge, which henceforth became his home. He occupied rooms in Trinity college till 1885, when he was elected to a professorial fellowship at Christ's college. In 1886 he became university librarian, and in 1889 Adams professor of Arabic. In 1888–1891 he delivered, as Burnett lecturer, three courses of lectures at Aberdeen on the primitive religion of the Semites. Early in 1890 grave symptoms of constitutional disease manifested themselves, and the last years of his life were full of suffering, which he bore with the utmost courage and patience. He never ceased to work, and when near his end was actively engaged in planning the *Encyclopaedia Biblica*, which he had hoped to edit. He died at Cambridge on March 31, 1894, and was buried at Keig. Small and slight in person and never robust in health, Robertson Smith was yet a man of ceaseless and fiery energy; of an intellect extraordinarily alert and quick, and as sagacious in practical matters as it was keen and piercing in speculation; of an erudition astonishing both in its range and in its readiness; of a temper susceptible of the highest enthusiasm for worthy ends, and able to inspire others with its own ardour; endowed with the warmest affections, and with the kindest and most generous disposition, but impatient of stupidity and ready to blaze out at whatever savoured of wrong and injustice. The sweetness and purity of his nature combined with his brilliant conversational powers to render him the most delightful of friends.

See the *Life* by J. S. Black and G. W. Chrystal (1912); *see* also James Bryce, *Studies in Contemporary Biography* (1903).

SMITH, SIR WILLIAM SIDNEY (1764–1840), English admiral, was born at Westminster on July 21, 1764, and entered the navy. In Jan. 1780 he was appointed lieutenant of the "Alcide" (74) after serving at Cape St. Vincent under Rodney; and in May 1782 was made commander of the "Fury" sloop, and promoted captain. He was knighted for his services (1790–92) in advising the king of Sweden during the war with Russia. In 1793 he assisted Lord Hood in the attempt to burn the enemy's ships at Toulon. In 1796 he was captured while hunting French privateers in the Channel, and imprisoned in Paris, whence he made his escape in 1798. In 1799 he left Constantinople, where he was plenipotentiary jointly with his brother, and hastened to the relief of St. Jean d'Acre, compelling Napoleon to raise the siege in May. For this exploit he received an annuity of £1,000. Smith co-operated with Abercromby in Egypt, and was wounded at Aboukir. Promoted rear-admiral of the blue in 1805, he was sent in 1806 to Sicily and Naples, and relieved Gaeta and captured Capri. Proceeding to Malta in 1807, he destroyed the Turkish fleet off Abydos, and in the following November blockaded the Tagus and assisted the Portuguese royal family to embark for Rio de Janeiro. Recalled from Rio de Janeiro, where he had been sent as commander-in-chief (1808), owing to his quarrel with the British minister, he was made a vice-admiral of the blue (1810) and in 1812 was sent to the Mediterranean, as second in command under Sir Edward Pellew. Made K.C.B. in 1815, and admiral in 1821, he died on May 26, 1840, at Paris. His self-assertion brought him into conflict with many of his contemporaries, including Nelson and Sir John Moore, but he was a daring and ingenious officer.

See Barrow, *Life of Admiral Sir W. S. Smith* (2 vols., 1848).

SMITH COLLEGE, an institution for the higher education of women, at Northampton, Mass. It was founded by the will of Sophia Smith (1796–1870) of Hatfield, who chose the neighbouring town of Northampton as the site of the college, and selected the first trustees. The college was chartered in 1871 and opened in 1875.

The equipment of the college in 1928 consisted of a campus of 87ac., including the Allen field for athletics; 48 dwelling houses for students, laboratories for zoology, botany, geology, physics, chemistry, psychology and phonetics, the Lyman plant houses and a botanic garden, an astronomical observatory, a library of 154,460 vols., the Hillyer and Tryon art galleries, a swimming pool, an infirmary, a students' building, an auditorium seating 2,400, two gymnasiums, Sage Hall for music, and other buildings.

All students enter by the examinations of the college entrance examination board. The undergraduate courses, which are chiefly elective, lead to the degree of bachelor of arts. Since 1920 an honours system has been in operation, by which selected students in their last two years concentrate on a special field of study under the direction of tutors, and are relieved from the routine of courses and class examinations. Graduate courses lead to the degree of master of arts and, more rarely, to that of doctor of philosophy. The Smith college School of Social Work, with an eight weeks' summer session and supervised field work in various cities in winter, trains social workers with a special equipment in psychiatry and prepares for the degree of master of social science. In 1927–28 the college had 225 teachers, 2,051 undergraduates, 77 graduate students, 89 in the School for Social Work. The fees for tuition are $400 a year for undergraduates, $200 for graduates. Board and room cost $500. About $100,000 is distributed annually in scholarships and fellowships. The invested funds of the college total (1928) $5,000,000 and the land, buildings and equipment have cost $6,500,000. In 1925 a scheme was initiated of sending students specializing in French to spend their junior year in study at the Universities of Grenoble and Paris under the direction of members of the college staff. Between 40 and 50 students now take advantage of this annually. An Institute for the Co-ordination of Women's Interests studies and experiments with methods of enabling women to maintain their intellectual interests, both cultural and professional, after graduation. The department of education conducts a Nursery school (in co-operation with a Parents' Association) and a progressive day school. The William Allan Neilson chair of research is at present devoted to psychology under the direction of Prof. Kurt Koffka. The college publishes the *Smith College Studies* in history, classics and modern languages, a series of volumes issued in celebration of its 50th anniversary and in the field of zoological science an internationally edited *Catalogue of the Hemiptera*.

The college is governed by a board of 15 trustees, four of whom are nominated by the alumnae (now numbering 10,762) and serve for eight years, the others, with the exception of the president, serving for ten years, and retiring in rotation. The first president was Laurenus Clark Seelye (1875–1910), the second, Marion LeRoy Burton (1910–17), and the third William Allan Neilson (1917–). (W. A. N.)

SMITH-DORRIEN, SIR HORACE LOCKWOOD (1858–), British general, was born on May 26, 1858. He joined the army in 1876, took part in the Zulu War and in the Egyptian campaign of 1882 and, attached to the Egyptian army, served at Suakim in 1884 and on the Nile in 1885–86. He took part in the Tirah campaign of 1897–98, in the final advance to Khartum in 1885 and later in South Africa. After being adjutant-general in India, he held the Aldershot command until 1912, when he was transferred to the Southern command.

On the death of Sir James Grierson in Aug. 1914, Sir H. Smith-Dorrien was appointed commander of the II. Army Corps. His troops received the brunt of the enemy's onset at Mons, and, although his action in giving battle at Le Cateau was criticised, it was subsequently recognized that it saved the British Army from disaster. Afterwards he commanded his corps at the battle of the Marne, on the Aisne, and during the severe fighting in Flanders in October and November. On the splitting-up of the Expeditionary Forces into two armies he was appointed to the command of the II. Difficulties with the commander-in-chief led, in April 1915, to his return to England where he was placed in charge of one of the Home Defence armies. In the following November he was chosen to take charge of the operations against German East Africa, but he fell ill on the voyage out, and had to return home. From 1918–23 he was governor and commander-in-chief of Gibraltar. After his retirement in 1923 he published (1925) *Memories of 48 Years' Service*.

SMITH'S FALLS, a town and outport of Lanark county, Ontario, Canada, on the Rideau river and canal, and the Canadian Pacific and Canadian National railways, 28 m. N.W. of Brockville. Pop. (1931) 7,108. It contains saw, shingle, woollen and planing mills, and large agricultural implement works, and has weekly steamer connection with Ottawa by the Rideau river and canal.

SMITHSON, HENRIETTA CONSTANCE (1800–1854), Irish actress, the daughter of a theatrical manager, made her first stage appearance in 1815 at the Crow Street theatre, Dublin, as Albina Mandeville in Reynolds's *Will.* Three years later she appeared at Drury Lane, London, as Letitia Hardy. She had no particular success in England; but in Paris, in 1828 and 1832, whither she first went with Macready, she aroused immense enthusiasm as Desdemona, Virginia, Juliet and Jane Shore. She had a host of admirers, among them Berlioz (*q.v.*), whom she married in 1833. They separated in 1840. She died on March 3, 1854.

SMITHSON, JAMES (1765–1829), British chemist and mineralogist and founder of the Smithsonian Institution at Washington, was born in France and first known as James Lewis Macie, taking the name of Smithson about the year 1800. He was educated at Pembroke college, Oxford. He published analyses of calamines and other papers in the *Annals of Philosophy* and *Phil. Trans.* The mineral name "smithsonite" originally given in his honour by Beudant to zinc carbonate, is now rarely used. In 1784 he accompanied Faujas St. Fond to the Western isles. He was elected F.R.S. in 1787. He died at Genoa on June 27, 1829. He bequeathed upwards of £100,000 to the United States of America to set up the Smithsonian Institution founded by act of Congress on Aug. 10, 1846.

See "James Smithson and his Bequest" (with portraits), by W. J. Rhees, and "The Scientific Writings of James Smithson," ed. W. J. Rhees, *Smithsonian Misc. Coll.*, vol. xxi. (1879–80).

SMITHSONIAN INSTITUTION, an American institution of learning in Washington, D.C., founded by the bequest of James Smithson (*q.v.*). His estate was left to a nephew, Henry James Hungerford, with the stipulation that should Hungerford die without issue the whole estate should go "to the United States of America to found at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge among men." Hungerford died without issue in 1835. There was much opposition in America to the acceptance of Smithson's bequest, especially by John C. Calhoun and others, who held that Congress had no power under the Constitution to accept such a gift, but it was accepted, largely through the efforts of John Quincy Adams.

Establishment.—In Sept. 1838 £104,960 in gold sovereigns was delivered from the clipper "Mediator" to the Philadelphia mint, where it was recoined into American money, $508,318.46; in 1867, after the death of Hungerford's mother, a residuary legacy of $26,210 was received and the fund then amounted to $650,000. By savings of interest, and by other gifts, notably that of $250,000 from Thomas George Hodgkins (d. 1892) of Setauket, Long Island, N.Y., the fund was increased. In 1928 it amounted to about $1,500,000. After 10 years of debate Congress accepted the trust and created by enactment an "establishment" called the Smithsonian Institution, consisting of the president, the vice-president, the chief justice and the members of the president's cabinet. It has a secretary, the executive officer of the institution, who is also the keeper of the National Museum. Smithson's money, a great fortune in that day, was lent to the U.S. Treasury, the Government agreeing to pay perpetually 6% interest upon it.

In the fundamental act creating the institution, Congress provided that it should be governed by a board of regents, composed in 1928 of the vice president and chief justice, three members of the Senate, three members of the House of Representatives and six private citizens, two of them residents of the District of Columbia. The fundamental act also provided for a library and for a museum, which was to contain "objects of art and of foreign and curious research, and objects of natural history, etc.," belonging to the United States. The museum was later designated the United States National Museum, but remains under the direction of the Smithsonian Institution.

The first meeting of the regents occurred on Sept. 7, 1846, and in the autumn of the same year they elected as secretary Joseph Henry (*q.v.*), then a professor at Princeton, known for his experiments on the electromagnet and other subjects relating to electricity. Under his guidance the institution took shape. Henry seized the unique opportunity offered by the opening up of the great western areas of the United States, to make collections of fauna and flora, and to study the Indian tribes. A principal feature of his administration, also, was the establishment of international exchanges of scientific literature. About 1900 there took shape, with international co-operation, Henry's idea of a catalogue of the scientific literature of the world, and the Smithsonian was made custodian of the United States branch of the organization.

The diffusion of knowledge was promoted by publishing (1) a series of periodical reports on the progress of different branches of knowledge; (2) occasional separate treatises on subjects of general interest; and (3) monographs on subjects investigated by experts both within and outside the institution. Henry opposed the scheme for the gradual formation of a general library under the charge of the institution, and in 1855 committed the board of regents to a repeal of the previous practice of spending one-half of the annual income on the museum and library, and this action was approved by an investigating congressional committee. In 1846 a plan was presented for the unification and systematization of weather observation under the institution. In Dec. 1847 an appropriation was made by the board for such meteorological research; in 1849 telegraphic transmission of meteorological intelligence collected by the institution was begun; in 1850 a standard "Smithsonian barometer" (Arnold Guyot's improvement of Ernst's improved Fortin "cistern barometer"), was first distributed; weather maps were successfully made in 1856. In 1870 the meteorological work of the institution was incorporated with the Signal corps, independent of the institution. Still later the U.S. Weather Bureau was established by act of Congress. After 1854 Henry's annual reports contained a general appendix with reports of lectures, such as were held under the auspices of the institution until 1865, summaries of correspondence, special papers, etc. Before 1870 meteorology bulked largely in these reports; after that year there was more North American archaeology and ethnology.

Development.—Spencer F. Baird (*q.v.*), Henry's successor, incorporated in the general appendix annual reports on the progress of the sciences, and he perfected Henry's system of international exchanges, under which the institution, through agents in the principal cities of the world, exchanges its own publications, those of other departments of the U.S. Government, and those of learned societies, for foreign publications. Baird had been at the head of the U.S. National Museum, a branch of the institution, before he became secretary of the institution, and the museum particularly was developed during his administration. It was built up around the collections of the U.S. Patent Office, which were turned over to it in 1858, and those of the National Institute, transferred to the Smithsonian in 1861, when the institute was dissolved. A part of the collection (including Smithson's collection) was destroyed by fire in 1865. The small art collection which remained was exhibited in the private Corcoran gallery until 1896. A new building for the museum was erected in 1881, and in 1911 the commodious and handsome Natural History building was added.

The museum gained much valuable archaeological and ethnological material from the exploring parties sent out under J. W. Powell; excellent ichthyological specimens through Baird's position as U.S. fish commissioner; and general collections from the exhibits made at the Centennial exhibition of 1876 by the United States and foreign governments. Its great collection of plants is known as the National Herbarium. The Bureau of American Ethnology was established as a branch of the institution in 1879, when the various organizations doing survey work in the West united as the U.S. Geological Survey, and anthropological and ethnological research was transferred to the Smithsonian Institution.

In 1887 Samuel P. Langley (*q.v.*), was appointed as assistant secretary of the institution, and succeeded as secretary upon Baird's death in the same year. In 1890 a small astrophysical observatory was built in the Smithsonian park; in 1891 an appropriation was made for astrophysical work and $5,000 was contributed by the executors of Dr. J. H. Kidder (1842–1889).

Langley's principal researches in the observatory were on the nature of the infra-red portion of the spectrum, and preliminary experiments indicating a possibility that variation of the sun produces important effects on the weather. His name is perhaps best known for his pioneering work in aeronautics resulting in the publication of *Experiments in Aerodynamics* in 1891, and *The Internal Work of the Wind* in 1893.

Under the terms of the Hodgkins bequest prizes were offered in 1893 for research and investigation of atmospheric air in connection with the welfare of mankind; in 1895 an award of $10,000 was made to Lord Rayleigh and Sir William Ramsay for their discovery of argon; and the Hodgkins medal was awarded to Sir James Dewar in 1899 and one to Sir J. J. Thomson in 1901. By acts of Congress of March 2, 1889, and April 30, 1890, the National Zoological Park was established under the institution; and in a park of 175 ac. in the valley of Rock Creek a small collection was installed which has since grown to be one of the foremost collections of animals in America.

Mrs. Harriet Lane Johnston (1833–1903) left her art collection to a national gallery of art, when such a gallery should be established, and in 1906 the supreme court of the District of Columbia decreed that the collection of the Smithsonian Institution was a national gallery, and turned this collection over to the National Museum, whose art collections have been called since that time the National Gallery of Art. They have been enlarged by the gift of a collection representing contemporary French artists, the Ralph Cross Johnson collection of old masters, the William T. Evans collection, the Eddy bequest, the Ranger bequest and others.

On Jan. 23, 1907, Charles Doolittle Walcott (*q.v.*) (1850–1927), eminent geologist and palaeontologist, was elected secretary. During his administration of almost exactly 20 years the outstanding events for the Smithsonian were the gift by Charles L. Freer, of Detroit, of the Freer Gallery of Art, together with a large testamentary endowment, and the establishment of the National Gallery of Art as a distinct branch of the institution separate from the National Museum. The Freer gift comprised more than 9,000 pieces, including works of American artists, especially Whistler, Tryon, Thayer and T. W. Dewing, and of Japanese and Chinese masters, including precious screens, ceramics and bronzes. Near the close of Walcott's incumbency, great need being felt to increase the unrestricted income of the Smithsonian, a strong movement was inaugurated among prominent Americans to promote an increase of several millions in the endowment.

On Jan. 10, 1928, Charles Greeley Abbot (1872–), astrophysicist and assistant secretary from 1918, was elected secretary, and has continued the researches begun by Langley on the variation of the sun's radiation, improving instruments and methods, and establishing three first class solar observatories in widely separated regions of the earth.

The Smithsonian park occupies a square equivalent to nine city blocks, almost exactly the same size as the Capitol grounds. The oldest building, that of the institution proper, was erected in 1847–1855. It is of seneca brown stone in a mingled Gothic and Romanesque style, designed by James Renwick, and is located in the S.W. part of the grounds. S.E. of it is the arts and industries building of the U.S. National Museum (330 ft.sq.), erected in 1881; and on the N. side of the park is the Natural History building of the National Museum (1911). S.W. of the original Smithsonian building is the Freer Gallery of Art. The noteworthy aeroplane exhibit, and the Astrophysical Observatory, occupy temporary structures S. of the original building. On the grounds is a bronze statue of Joseph Henry by W. W. Story.

The institution publishes: *Annual Reports* (1846), in which the *Reports* of the National Museum were included until 1884—since then the Museum *Reports* have appeared as separate volumes; *Smithsonian Contributions to Knowledge* (1848); *Smithsonian Miscellaneous Collections* (1862); *Proceedings of the United States National Museum* (1878); *Bulletins of the United States National Museum* (1875), containing larger monographs than those printed in the *Proceedings;* and occasional *Special Bulletins; Annual Reports of the Bureau of American Ethnology* (1880); *Bulletins of the Bureau of American Ethnology* (1887), including *The Handbook of American Indians North of Mexico* (1907), pt. 1 being Bulletin 30; and *Contributions to North American Ethnology* (1877–1893); *Annals of the Astrophysical Observatory* (1900); and *Catalogues of the National Gallery of Art* (1922).

SMITHSONITE, a mineral species consisting of zinc carbonate, $ZnCO_3$, and forming an important ore of zinc. It is rhombohedral in crystallization and isomorphous with calcite and chalybite. Distinct crystals are rare; they have the form of the primitive cleavage rhombohedron. Botryoidal and stalactitic masses are more common, or again the mineral may be compact and granular or loose and earthy. The hardness is 4·5; specific gravity, 4·4. The colour of the pure mineral is white; more often it is brownish, sometimes green or blue: a bright-yellow variety containing cadmium has been found in Arkansas, and is known locally as "turkey-fat ore." The pure material contains 52% of zinc, but this is often partly replaced isomorphously by small amounts of iron and manganese, traces of calcium and magnesium, and sometimes by copper or cadmium.

Smithsonite is found in beds and veins in limestone rocks, and is often associated with galena and blende. It is a product of alteration of blende, having been formed from this by the action of carbonated waters; or in many cases the zinc sulphide may have been first oxidized to sulphate, which in solution acted on the surrounding limestone, producing zinc carbonate. The latter mode of origin is suggested by the frequent occurrence of smithsonite pseudomorphous after calcite, that is, having the form of calcite crystals. It occurs in large amount in the province of Santander in Spain, in Missouri, and at several other places where zinc ores are mined. The best crystals are from Chessy near Lyons and Broken Hill in Northern Rhodesia. A translucent botryoidal smithsonite banded with blue and green is found at Laurion in Greece, and has sometimes been cut and polished for small ornaments. In Britain, smithsonite is usually called calamine.

SMOHALLA or **SHMOQULA** (*i.e.*, "preacher"), a religious prophet of the North American Indians and founder of the sect called Dreamers, was born in the Columbia river valley about 1820 and became chief of the Wanapum tribe in Washington State. On one occasion after a tribal fray he was left for dead, but recovered and journeyed through California, Mexico, Arizona and Nevada back to his home on the upper Columbia, where he announced that he had been in the spirit world and had returned with a new revelation. This consisted in a return to primitive Indian customs, and a ritual combining genuine Indian features with what he remembered of Roman Catholic ceremonies. Smohalla had frequent trances and his influence extended over most of the tribes of eastern Washington and Oregon and western Idaho. The sect gave much trouble from 1870 to 1885 by refusing to come under reservation restrictions. A church was established at Priest Rapids on the upper Columbia, and one at Union Gap on the Yakima reservation. Smohalla died about 1908 but his religion continued to be influential.

See J. Mooney, "The Ghost-dance Religion," in *14th Ann. Rep.* Bureau of Ethnology (1896).

SMOKE: IN WARFARE. The first historical reference to the use of smoke in war, was the miracle whereby the Israelites were protected during their march from Egypt to the Promised Land (Exod. xiv. 19). In this old Biblical story of the Israelites lies the whole essence of the use of smoke in war—the blinding of one's enemy. In the civil wars of the Roman empire both Caesar and Pompey used smoke as a weapon of attack, chiefly in landing operations.

Examples from History.—There appears to be little or no mention of the use of smoke for many centuries after this, but we find an instance in the 17th, when in 1632 Gustavus covered his

crossing of the Lech in face of Tilly by a smoke screen created by setting fire to wet straw, and another when on July 2, 1667, the Dutch fleet appeared off Landguard (near Harwich) and its ships took up their position to bombard it from all sides at once. Some of them were placed exactly to windward so that the smoke of their guns swept along the beach, and so covered the landing of their troops from the sight of the mariners in the fort.

In the battle of Seneff in 1674 smoke was used by the French when, as a strategem to cover their retirement, they hung up their lighted "matches" in the hedges. In 1770 Charles XII. of Sweden used smoke in the crossing of the Dvina in his campaign against the Saxons. On this occasion specially constructed barges carrying tar barrels were used.

The Waterloo campaign had a great effect on the use of smoke in war, as it was realized at this time to what an enormous disadvantage the defence were put by the use of the black powder, which wrapt them in clouds of smoke, but it was not till 1885 that the introduction of smokeless powder was brought about by the French. Domokos, in the Turko-Greek war of 1897 was the last battle fought in Europe with smoke powder, and it is a remarkable fact that it was not till 1915—nearly 20 years later—that a means was devised of projecting smoke on an enemy on the battlefield.

An experiment in covering the attacking troops by throwing forward smoke candles, such as were used for testing drains, was tried at Aldershot before the South African war and was rightly condemned, as the whole essence of the success in the use of smoke is the element of surprise and the blinding of the defenders by the attackers which can be done by smoke projection. No mention of the use of smoke is made in the histories of the South African and Russo-Japanese wars, though the Boers on occasions lit veldt fires to cover their withdrawal.

The World War.—The first instance of the use of smoke in the World War was probably the lighting of a haystack north of the La Bassée canal in October 1914, which enabled a company of the Devonshire Regiment to be withdrawn. Shortly after this a battery of artillery, in somewhat like manner, made good its withdrawal. At Loos in September 1915 smoke was wrongly used as a blind by lighting candles in British trenches, and thus brought down heavy shell fire. From this battle may be dated the realization of the necessity of the *projection* of smoke and its use in attack, and danger to any defence.

By November 1916 smoke shells were in use in some divisions in France, but it was not, however, until the battles of Arras, 1917, when they were used by the 9th (British) Division that the art of accurately projecting smoke shells, and their great value, came to be appreciated. Many instances in 1917 and 1918 are on record when numbers of lives were saved by the invention of smoke shell, and when victories were gained with a minimum of casualties by the use of smoke. The Germans quickly copied the British, and used it in their offensive of March 1918, while the Australians used it to cover their withdrawal over the Piave in May 1918. The navy used smoke with conspicuous success at Zeebrugge on St. George's day, 1917, when fast coastal motor-boats greatly assisted the blocking operations by blinding the enemy's observation and shore guns.

Smoke, which may be used in war by artillery, infantry, aircraft and tanks, has certain inherent disadvantages, in particular the blinding of observation, and the variability of wind—the latter is a serious difficulty—but by practice all difficulties can be overcome, and the experience of the World War proved that the advantages created by the use of smoke far outweigh the disadvantages. It may be said of smoke that, if properly used, it will on almost every occasion in the attack, and also in the withdrawal, save many casualties. By its use the utmost is made of "fire power" and man power is concealed until the decisive stages. Infiltration—an art in war—is facilitated and losses are greatly reduced through the use of cover by ground and cover by smoke. The chief object in the use of smoke-tactics, is, as far as possible, to impose on the defenders the conditions of night, while the attackers have the conditions of day, and thereby effect surprise and reduce casualties. To summarize the use of smoke in war it may be said that it is used to obtain concealment of movement which begets surprise. (P. R. W.)

SMOKE AND SMOKE PREVENTION. Smoke and its Production.—Smoke is a general term applied to the visible exhalations from burning materials. The character of smoke varies according to its source, which may be a waste heap, a bonfire or a cigarette; but the smoke which is produced in by far the largest quantities, and which on account of its injurious effects has become a serious economic problem, is that associated with the general use of raw bituminous coal as a fuel.

Nearly all fuels consist essentially of carbon, hydrogen, oxygen and nitrogen, in various proportions and variously combined. In addition they usually contain a little sulphur, while in solid fuels varying amounts of incombustible mineral ash are also incorporated. If complete combustion were always attainable no fuel would emit smoke, the final products in such an ideal case being limited to carbon dioxide, water vapour and free nitrogen, all quite innocuous gases, and invisible unless the water vapour condenses to a cloud of steam. There would, however, if sulphur were present, also be produced small quantities of sulphur dioxide gas, which, although also invisible, has a pungent smell, and in contact with air and moisture tends rapidly to be converted into a corrosive acid; while the mineral constituents would remain unburned in the form of ash.

To achieve such finality it is necessary only that a fuel should be brought into contact with enough air for full oxidation while maintained at a temperature sufficiently high for combustion to take place. These conditions, although apparently simple, are by no means easy to realise, and in practice some proportion of a fuel always eludes complete combustion. The unburned products vary widely both in amount and in composition according to the nature of a fuel and the manner of its use, being in some circumstances inappreciable, in others very large. They are moreover not necessarily in the form of smoke, since with insufficient air carbonaceous materials may emit gaseous intermediate products such as carbon monoxide and unsaturated hydrocarbons; but whether or not smoke is produced, imperfect combustion is always indicative of thermal loss. The heat which a given weight of carbon liberates in oxidising to carbon monoxide, for instance, is less than one-third that generated by its complete combustion to carbon dioxide.

Thorough admixture with air is relatively easy to secure in the case of gaseous fuels, which in properly constructed and properly adjusted burners produce neither smoke nor other unburned products in appreciable quantity. An inadequate air supply, however, or the chilling or smothering of the flames, may result in the evolution of unburned gaseous products, including carbon monoxide and oxides of nitrogen, both highly poisonous; or in extreme cases may even cause the deposition of soot.

Smoke from Solid Fuels.—Owing to the relatively high density of solid fuels, the problem of bringing them into contact with sufficient air for complete oxidation is greatly intensified, and, even with an air supply far in excess of that theoretically required, perfect combustion cannot in practice be counted upon. Certain forms of solid fuel, however, such as anthracite, which is naturally nearly free from volatile matter, or coke, from which the volatile matter of the original coal has been artificially extracted, can be burned, if not completely, at least without smoke emission. With bituminous coals, on the other hand, smoke production to a greater or lesser degree, according to the circumstances, is practically unavoidable; for such coals are subject to decomposition at temperatures below the ignition point, with the evolution of combustible gases and condensable tarry vapours. These are of so complex a character, and under the action of heat are subject to such complicated chemical changes, that although the more readily ignitible constituents may burst into spasmodic flames, others almost inevitably escape unburned. Coal smoke consists of such unconsumed distillation products, in association with carbon and tarry matter condensed by premature chilling of flame, together with dust and ash entrained by the upward rush of hot air and gases from the grate. Some of this settles on the walls of the flue as soot; the remainder is carried

out through the chimney into the atmosphere with the excess air and gaseous products of combustion, both burned and unburned.

Since 1920 the total home consumption of coal in Great Britain has averaged roughly 175 million tons annually, of which about 40 million tons has gone to meet domestic requirements, most of the remainder being burned in industrial furnaces, mainly for the production of steam. Coals of relatively low volatile content are largely absorbed for steam raising purposes and when due attention is paid to furnace design, stoking procedure and draught control, they can be burned without much smoke and with remarkably high efficiencies of steam generation. On the other hand, in certain metallurgical furnaces, etc., it is claimed that a smoky atmosphere is essential.

Most of the British domestic coal supplies are drawn from highly bituminous seams, and since they are burned in a very haphazard and careless manner, with little possibility of proper air regulation, it is not surprising to learn that the domestic chimney is on the whole responsible for far more than its proportionate share of smoke and soot. In London, domestic smoke forms more than two-thirds of the total, but in centres of iron, steel or pottery manufacture, or in the immediate vicinity of large works, industrial smoke may obviously preponderate. Apart from considerations of its quantity, however, domestic smoke is in character dissimilar to, and far more objectionable than, factory smoke, in so far as it contains relatively high proportions of tar, while boiler smoke consists largely of ash and dust. This point is amply illustrated by the following analyses, due to Professor Cohen, of soot from similar coal burned respectively in a sitting-room grate and a boiler furnace.

Analyses of Soot from Domestic and Boiler Fires

	Original coal	Domestic soot	Boiler soot			
			Base	13 ft. up	20 ft. up	110 ft. up (top)
Carbon	69·30	40·50	19·24	16·66	21·80	27·00
Hydrogen	4·89	4·37	2·71	0·86	1·44	1·68
Nitrogen	1·39	4·09	0·23	0·00	1·18	1·09
Ash	8·48	18·16	73·37	75·04	66·04	61·80
Tar	1·64	25·91	0·09	0·28	0·80	1·14
Sulphur	1·74	2·99	2·76	2·07	2·58	2·84
Chlorine	0·27	5·19	0·11	0·75	1·46	1·60
Acidity	0·0	0·39	1·62	1·04	0·58	0·47

Bituminous coal normally contains 1% to 2% of sulphur. Most of this is evolved in the gaseous form; but some is found in the soot, mainly in the combined state as ammonium sulphate; and some is left behind in the residue. The sticky nature of tarry soot causes it to adhere tenaciously to objects with which it comes into contact, and since it usually contains free sulphur acids in addition to ammonium sulphate, it has a destructive action upon stone, fabrics, metals and vegetation, apart from the widespread dirt and discolouration which it causes.

A number of investigators have made direct determinations of the actual amounts of soot emitted from burning coal, usually by aspirating a measured volume of the flue gases through suitable filters. Roberts-Austen, in analyses carried out in connection with the 1884 London Smoke Abatement Exhibition, obtained from domestic grates soot equivalent to 6% by weight of the coal burned, a value in agreement with later measurements by Cohen and Hefford. Sinnatt, however, in experiments undertaken for the Manchester Corporation, found a corresponding soot loss of only 2%, but unburned gaseous products represented thermal losses of as much as 15–20%. Scheiner-Kestner's boiler furnace soot determinations gave values averaging under 1%, but probably in small inefficient plant, and certainly in other types of industrial furnaces, this amount is often exceeded. Further, it is not always feasible, even in efficient boiler practice, to avoid altogether an escape of unburned gaseous products. For while it is desirable in the interests of economy to aim at complete combustion, increase of excess air to this end is justifiable only so long as the additional heat generated is sufficient to offset the increased losses in sensible heat.

Investigation of Atmospheric Pollution.—In 1912, as the outcome of a conference held in London under the auspices of the Coal Smoke Abatement Society, a voluntary committee was appointed for the investigation of atmospheric pollution. Initiated as a private body, this later became an advisory committee of the Meteorological Office, but in 1927 responsibility for the direction of subsequent work was transferred to the Department of Scientific and Industrial Research. Annual reports of the investigations undertaken and the results obtained have been published by H. M. Stationery Office. The chief aim throughout has been the compilation and collation of systematic information respecting the nature and amount of atmospheric pollution in various localities, with a view to obtaining both seasonal variations and variations from place to place; but investigations of a more academic nature have also been undertaken. Standard methods of measurement have been adopted for the statistical work, which has been carried out in co-operation with various local authorities and institutions.

Town air always contains large numbers of suspended solid particles, which of course are not derived exclusively from smoke, but include also dust, vegetable matter, etc. These tend gradually to settle down under the force of gravity. The impurities so deposited can be caught in a suitable receptacle and analysed, and if collected under similar conditions in different places afford material for interesting comparisons. The organisation of an investigation on these lines has formed the chief work of the above-mentioned committee, and in 1927 seventy-nine deposit gauges, maintained by thirty-four authorities, were in operation. These return monthly records not only of the total weight of deposited matter, but also of its insoluble and soluble constituents separately. The insoluble fraction is further divided into combustible and ash, and is analysed for sulphates, chlorine and ammonia. The lowest deposits, measured in the smaller towns or in suburban districts, amount annually to some 75–100 tons per square mile; the highest deposits, measured in the heart of large industrial areas, reach ten times these figures.

One of the most interesting features of these observations is the gradual alteration shown in the composition of the deposit from town to country, particularly in regard to carbonaceous matter and sulphates. In the heaviest deposits the proportion of carbonaceous and tarry matter is relatively high, usually amounting to 20–30% of the total, but in the lightest deposits it may fall as low as 5–10%. On the other hand sulphates, which (as SO_3) in city deposits account for only 5–15% of the total, may rise to 20–30% in country districts. The relation between the different constituents is shown in the following table derived from the Reports of the Atmospheric Pollution Committee for two selected stations, one, Malvern, a remarkably clean one, the other, Newcastle-on-Tyne, representing a heavy deposit.

Constituents of Matter Deposited from the Atmosphere

	Malvern (3 years' average)		Newcastle-on-Tyne (5 years' average)	
	Tons per sq.mile	% of total	Tons per sq.mile	% of total
Total solids	74	100	602	100
Tar	..	..	7·2	1·2
Carbonaceous matter	4·9	6·6	128·2	21·3
Insoluble ash	11·0	14·9	269·7	44·8
Loss on ignition	17·5	23·7	63·8	10·6
Soluble ash	40·6	54·8	133·0	22·1
Sulphates (as SO_3)	17·2	23·2	62·1	10·3
Chlorine	4·3	5·8	21·7	3·6
Ammonia	0·5	0·7	3·6	0·6

Selective effects are to be expected in the deposition of atmospheric impurities, for the larger particles naturally fall most quickly and are therefore deposited in the more immediate neighbourhood of their source; but there are also present in smoke numerous particles so small that they become thoroughly mixed up with the air by eddies and may be carried many miles on the wind before ultimately reaching the ground or coming to rest on buildings or vegetation. Owens has devised an automatic

instrument for filtering hourly through special discs of paper a measured volume of air, and so obtaining information in regard to the progressive changes in the quality of black suspended matter. In London the suspended impurity is at its minimum between midnight and 6 A.M., subsequently rising rapidly owing to the lighting of fires, to a maximum at 9 or 10 A.M., after which it gradually falls again; the summer charts are naturally less black than the winter ones. Sundays are on the whole the cleanest days, and certain characteristic differences between different week-days, varying from place to place, are exhibited. Owens has also examined microscopically the number and nature of the suspended atmospheric impurities, and has been able in some cases to recognize salt crystals, mould cells, etc., in addition to soot particles and fused ash.

Evil Effects of Smoke.—Smoke not only damages health, property and vegetation, but in addition entails greatly increased expense in general maintenance, washing, cleaning, and artificial lighting. It is also indicative of a loss of fuel which in soot alone probably amounts to at least 2 million tons annually, while unburned gaseous products of combustion are responsible for still more serious thermal losses.

The duration of sunshine in such towns as Leeds, Sheffield and Manchester is in the winter months less than half that in outlying districts. In summer the deficiency is less marked but the intensity is at all times impaired, particularly in respect of the ultraviolet rays, which are now recognized as being so essential to health. A similar state of affairs holds in London but a steady improvement has been in progress for many years, and while in the period 1881–1885 the City of London and Westminster received only 20% of the sunshine registered at Kew, by 1916–1920 the corresponding proportion had risen to 53%.

Were it not for the action of the wind in spreading smoke, and its tendency to rise to the upper layers of the atmosphere, which normally are cooler than those down below, fog would be an everyday occurrence in thickly populated districts. Still weather, indeed, is in winter usually accompanied by more or less dense smoke fog, or haze, especially since on cold, clear nights radiation to space chills the surface layers of air and is liable to produce in the atmosphere a "temperature inversion," or increase of temperature with height, which checks the upward drift of chimney products. Smoke also contains hygroscopic particles which act as nuclei for the condensation of water vapour and tend to produce wet fogs in chilled air. As might be expected, not only the number of carbon particles but also the amounts of carbonic and sulphurous acid rapidly increase during fog.

The depressing effects of dirt and gloom perhaps scarcely need be insisted upon, but the exact relation between smoke and physical welfare is impossible to assess, owing to the large number of other contributory factors. Smoky fog is certainly the signal for an increase in the number of deaths from pulmonary and cardiac diseases, but since such fogs are associated with special types of weather they are not necessarily its sole cause. Cohen and Ruston, however, quote an interesting investigation by Ascher, who by a comparison with industrial and non-industrial areas was led to the conclusion that coal-dust, smoke and soot increase the death rate from acute lung diseases.

The sulphur acids in soot or rain attack and destroy building materials, particularly limestones, slates and zinc. Sulphuric acid reacts with the carbonates of limestone, turning them into much more soluble sulphates, which are dissolved out by rain, often to be precipitated later in disfiguring incrustations. A simultaneous increase of volume tends to cause the stone to flake away, disintegration being especially rapid if the sulphates are formed in cracks or flaws, for instance in stones possessing marked cleavage planes. Sandstones are not so directly affected as limestones, unless they contain a calcite binding material, the destruction of which may result in large masses being dislodged.

The contrast between town and country gardens makes sufficiently apparent the detrimental effects of smoke upon vegetation. A deposit of soot, apart from the corrosive action of its acid constituents, not only impedes the transpiration of plants but also acts as a screen to sunlight. Acid rain is also directly harmful to plant life and affects adversely the soil, although soot is a valuable manure. The vitality of any type of vegetation usually suffers progressively as an industrial centre or large town is neared; crops diminish and reproductive powers are enfeebled. Evergreens become deciduous or may perish altogether, while many hardy perennials have to be replanted yearly. Some plants refuse altogether to grow in urban districts, others appear to be able to survive after a fashion almost anywhere.

Prevention of Smoke.—Broadly speaking, the prevention of smoke is to be sought both in improved methods of burning raw coal and in a wider development of the pre-treatment of coal for the production of potentially smokeless alternative fuels, such as gas and coke.

There are grounds for regarding hopefully the prospects of industrial smoke abatement. The observation of scientific principles in furnace design and air regulation coupled with the adoption of continuous mechanical stoking have made possible the almost smokeless operation of modern large scale steam boilers, even when working on bituminous coals. Smokeless combustion is less easy to achieve in small hand-fired boiler furnaces, particularly in the periods immediately following the opening of the fire-door and the introduction of fresh charges of fuel; for the chilling effect of the cold fuel and the accompanying inrush of cold air, together with the increased resistance of the deeper fire-bed, tend to the escape of unburned distillation products. Careful and systematic stoking at short intervals, however, by maintaining a fire of even depth with uniform air supply, can give surprisingly good results, and it is quite feasible in such a manner to improve greatly smoky plant. Courses of instruction in furnace manipulation have been inaugurated in a number of large industrial towns, and the education of stokers is under consideration by a London Joint Committee on Smoke Abatement appointed in 1927.

Further, there is ample evidence to prove that coke is a convenient and efficient boiler fuel, capable of giving results not inferior to those obtainable with coal. Its bulkiness, however, necessitates the use of relatively large furnaces, and the substitution of coke for coal in plant which is already hard-pressed to meet adequately the demands, would probably result in failure. There is taking place, especially in small-scale furnaces, a gradual development of the use of gas and oil, which not only can be burned without thick smoke, but contain less sulphur than coal. The possibilities of pulverised fuel are also attracting attention; in this form solid fuel can be burned completely, but the sulphur products are of course not reduced, and unless special precautions are taken a large proportion of the ash may be carried into the atmosphere as a gritty dust. The question of the necessity for smoke production in exempted trades and special processes is a controversial one, but there are known methods of removing soot and dust particles from flue gases, for instance by washing out with water, by centrifugal action or by electrical precipitation, though these naturally entail a certain amount of expense. Gas firing is being successfully adopted in certain branches of the pottery industry and both gas and electrical furnaces are making some headway in formerly smoky metallurgical processes; while for power production the use of electricity is steadily developing.

There is little hope of burning bituminous coal smokelessly in domestic appliances and the only satisfactory solution in this field, apart from the wider adoption of central heating for large buildings, lies in its replacement by smokeless fuels. The possibilities of such a course are governed mainly by economic considerations. For certain purposes, such as cooking and intermittent heating gas, or in more limited circumstances, electricity, compares favourably with coal even in running cost; but unfortunately at present prices the complete elimination of solid fuel is not feasible. Gas coke and anthracite suggest themselves as alternatives to coal, but both are somewhat difficult to ignite and, although suitable for use in stoves or independent boilers, they are not always altogether convenient in ordinary grates. Further, anthracite is expensive, even after taking into account its high calorific value. Hence the widespread interest which has been aroused in the possibility of establishing on a commercial scale, low temperature carbonisation processes for the production from

coal, at a competitive price, of ignitible solid smokeless fuels.

Legislation Against Smoke.—As early as 1306 a Royal proclamation was issued, forbidding the use of coal in London, followed by a Commission to punish miscreants "for the first offence with great fines and ransoms, and upon the second offence to destroy their furnaces." A further proclamation issued during Elizabeth's reign made illegal the burning of coal during the periods Parliament was sitting. Nevertheless its use continued, for the great forests were dwindling before the agricultural needs of an increasing population, and wood was becoming both scarce and dear. In 1648 Londoners unsuccessfully petitioned Parliament to prohibit the importation of coal from Newcastle on account of the injury suffered from smoke.

The extraordinary industrial activity of the 19th century gave the coal industry further impetus and by 1819 the smoke nuisance had become so conspicuous that Parliament appointed a Committee to enquire how far persons using steam engines and furnaces could erect them in a manner less prejudicial to public health and comfort; but although it was reported that evidence bore out the practicability of smoke prevention, no active steps were taken. Further Select Committees in 1843 and 1845 achieved some practical result; for sections were inserted in the Railway Clauses Act of 1845 requiring locomotives, and in the Town Improvement Clause Act of 1847 requiring factory furnaces, to consume their own smoke.

Between 1875 and 1926 English law relating to the excessive emission of smoke from industrial chimneys, with the exception of London, was administered under clauses in the Public Health Act 1875, which enacted that "any fireplace or furnace which does not, as far as practicable, consume the smoke from the combustible consumed therein . . . shall be deemed to be a nuisance," provided "that where a person is summoned before any Court in respect of a nuisance from a fireplace or furnace, the Court shall hold that no nuisance is created within the meaning of the Act if it is satisfied that such fireplace or furnace is constructed in such a manner as to consume as far as practicable (having regard to the nature of the manufacture or trade) all smoke arising therefrom; and that such fireplace or furnace has been carefully attended to by the person having the charge thereof." It has not been customary to attempt to convict under this clause, owing to the difficulty of defining the term "practicable," advantage usually being taken of a further and more workable clause that "any chimney (not being the chimney of a private dwelling-house) sending forth black smoke in such quantity as to be a nuisance, shall be deemed to be a nuisance liable to be dealt with summarily in the manner provided by the Act." Neither of these clauses was applicable to mines or to certain specially exempted metallurgical processes such as smelting and the conversion of pig iron into wrought iron. London was covered by very similar but somewhat more severe provisions in its own Public Health (London) Act 1891, while certain modifications of the general clauses of the 1875 Act were introduced in various local Acts. Scotland also had separate legislation.

The Public Health (Smoke Abatement) Act 1926 was largely the outcome of the work of a Departmental Committee on Smoke Abatement charged to examine the existing state of the law and its administration, and to make proposals to Parliament prior to its amendment. This Act modifies previous clauses by the important phrase "notwithstanding that the smoke is not black smoke," although a conviction cannot be secured if the offender is able to prove that he "has used the most practical means for preventing the nuisance." Local authorities are empowered to "make by-laws regulating the emission of smoke of such colour, density or content as may be prescribed by the by-laws," and, further, to combine in carrying out their duties. Advantage of this latter provision was immediately taken in several districts. There should result a greater degree of uniformity in the definition of smoke nuisances. Concessions to metallurgical industries are retained and the Minister of Health is empowered to extend these by Provisional Order to other trades or processes. Domestic grates are also exempted, but power is given to make by-laws requiring the provision in new buildings other than private dwelling-houses of such arrangements for heating and cooking as are calculated to prevent or reduce smoke emission.

Owing to the wider use of central heating, the more recent development of industry, and the greater regard for technical training, the smoke nuisance is less apparent on the Continent of Europe than in Great Britain, and other European countries have not parallel smoke legislation. Certain measures, however, both national and local, are in force. In Germany, for instance, particulars of projected boiler or furnace installations must be subjected to the police authorities for examination by technical experts and advertised in order that complaints of possible damage may be submitted. In Paris the Préfet de Police has instituted a committee to enquire into remedial measures against smoke.

UNITED STATES

Many efforts have been made by American cities to mitigate the smoke nuisance. In addition to causing great economic losses by injuring merchandise, defacing buildings, ruining contents of homes and by the waste of the fuel value, smoke is probably a predisposing cause of pulmonary diseases and by obscuring the sun's ultra-violet rays is undoubtedly prejudicial to health. Previous to 1917 many American cities had smoke regulations which, however, were not widely observed, and during the World War, regulations were held in abeyance. With the return of normal conditions health organizations met with considerable interested opposition, public apathy and often official indifference. In 1924 more than 50 American cities had smoke regulations. The administration of these was variously under the jurisdiction of health, boiler inspection, building departments or departments of public safety. New York city, Chicago, Baltimore, Philadelphia, Louisville, Denver and Columbus, O., were cities in this class. Milwaukee, Cincinnati, Salt Lake City, St. Louis and Harrisburg, Pa., had independent bureaux or departments for the purpose.

A smoke advisory committee, composed of engineers co-operating with the New York city department of health, reported in Dec. 1927, the results of a survey. The report declared that inasmuch as the supply of Pennsylvania anthracite was rapidly becoming exhausted, smoke-producing coal would necessarily become New York's main future supply. The report affirmed, however, that smoke from soft coal could be reduced at least 50% by suitable coal-burning appliances and careful supervision. The increasing substitution of fuel-oil and gas for coal promised beneficial results. By 1921 fuel-oil had replaced coal in the sugar, glass and certain other industries. This movement went on both in the east where anthracite was used and in the west where bituminous coal is the chief domestic fuel. Many of these were installed in heaters formerly using coal. The railways, long responsible for a great part of the smoke in urban districts, used 70,000,000bbl. of fuel-oil in 1925.

SMOKE-BOX is the chamber at the front end of a locomotive boiler (or boiler of similar type for steam rollers and portable engines), by which access is given to the fire-tubes for cleaning or repair purposes. The blast-pipe leading the exhaust steam from the cylinders stands up into the smoke-box and increases the draught. Leakage of air into the box is prevented by fitting a very rigid dished door, tightly seated by a clamping arrangement. Extra fittings to the smoke-box in some locomotives include a feed-water heater, or a superheater, while a spark arrester is essential in certain countries.

SMOKELESS DOMESTIC FUEL. Attention has been increasingly drawn to this subject of late years, and many organizations have carried out useful propaganda in relation thereto. By the more scientific consumption of fuel, not only could enormous waste be obviated but the atmosphere of towns would be rendered vastly clearer and the health of the residents enhanced. (*See* article COAL AND COAL MINING, under Origin and Occurrences, Composition and Varieties, Chemical and Physical Characteristics.)

The more bituminous a coal is, that is to say, the higher the volatile hydro-carbon content and consequently the more fuliginous it is the more smoke it makes in burning. But even in the case of such coals, the volume of smoke in burning can be considerably reduced by mixing excess of air with the burning gases, evolved from the coal, before the temperature has fallen below the point necessary for combustion; for smoke is composed of particles of unconsumed carbon. In order to understand the reason for this we have only to realize what smoke is and how it comes to be formed. If the air feeding a fire is too limited, or the temperature too low to effect the combination of the carbon in the coal with the oxygen in the air, the atoms of carbon will combine with each other to form molecules of carbon which will collect in solid particles which it is very difficult to supply with sufficient air of a temperature high enough for combustion, and so the particles pass up the chimney with the gases (chiefly carbon dioxide) into the atmosphere. The admission of too much unheated air also conduces to the formation of smoke by reducing the temperature of the fire.

Electricity for heating and cooking may eventually take the place of coal, but at present is too costly. The use of gas for these purposes has grown considerably of late years, and it certainly produces a smokeless fuel, but the use of gas has its disadvantages. The use of anthracite where burned in stoves in the house, or to afford the heat in a central heating system, has greatly increased in recent years. It can be burned with difficulty in the open grate, but is seldom so used. It burns with little or no flame and gives out great heat, but requires, for its economic application, special air feeding arrangements. "Gas" coke, *i.e.*, coke made at gas works, because it is softer and more open than metallurgical coke, is largely used for central heating and is sometimes burned in the open grate, either alone or mixed with bituminous coal.

Many processes have been evolved and some carried into practice for providing a low temperature coke suitable for the domestic hearth, and it would appear likely that the time is not far distant when this class of fuel will be in extensive demand for heating, whether in the open grate or in stoves, and for cooking.

SMOKELESS POWDER: *see* EXPLOSIVES.

SMOKE-TREE (*Cotinus Coggyria,* formerly *Rhus Cotinus*), a spreading shrub, sometimes 15 ft. high, of the cashew family, the Anacardiaceae, native to southern Europe and eastward to central China, and widely planted for its feathery flower clusters and attractive foliage. The very similar American smoke-tree (*C. americanus*), a tree sometimes 40 ft. high, is found from Kentucky and Missouri southward to Texas. The indigo-bush (*Dalea spinosa,* fam. Leguminosae), sometimes 25 ft. high, native to the deserts of south-eastern California, adjacent Arizona and Mexico, is also called smoke-tree.

SMOLENSK, a province of European Russia, smaller than the pre-1917 province of that name. Area 57,200 sq.kilometres. Pop. (1926) 2,258,064. It is bounded on the west by White Russia, on the north by Pskov and Tver, on the east by Moscow and Kaluga and on the south by Briansk. The Central Russian plateau occupies much of the province.

The Vazuza and Gzhat, tributaries of the Volga, have cut a deep valley opening northwards towards Rhzev, but most of the river valleys open towards the western plain. The Dnieper and its tributaries the Vop, Vyazma, Sozh and Desna, rise in the province but are not navigable here, though timber is floated on them. The Kasplya and Mezha, flowing into the Dvina, and some of their affluents, are navigable for small boats. The Ugra, flowing eastwards into the Oka, also forms a channel for floating timber.

The plateau region is composed of carboniferous limestone, the western plain mainly of tertiary sands, marls and ferruginous clays, covered with boulder clay. Post-tertiary sands cover some areas, and the marshy depressions, which are a marked feature of this morainic region, and which are a source of malaria, are filled with peat-bogs. These are a potential source of wealth in view of the increasing use of peat as fuel in electricity generating stations. There are patches of forest everywhere, most dense in the north-west and north, and thinning out to the south-west. The soil is of a clayey or sandy forest type, not favourable to agriculture.

The climate is somewhat modified by proximity to the western oceanic régime; average January temperature at Smolensk 13·5° F, average July temperature 67·2° F, rainfall about 20 in. per annum.

In spite of the poor soil, agriculture is the main occupation, the chief crops being rye, oats, potatoes and flax, with smaller quantities of buckwheat, barley, hemp and makhorka tobacco. The type of farming is poor, the three field system prevailing, but of late years energetic campaigns have been carried out with a view to the introduction of a better rotation of crops, with a greater sowing of clover, lucerne and root crops. There is much need for better drainage of the marshy soils, and beginnings have been made in some districts. The soils require heavy manuring.

Sheep, cattle, pigs and horses are bred, and the problem of their pasturage has been much eased since the 1917 revolution. Previous to that time the peasants had little access to the meadow and pasture lands, which were chiefly in private ownership. A dairy industry is springing up; poultry is increasingly kept and Yorkshire breeds of pigs are being introduced with a view to developing a bacon industry in conjunction with dairying. The improvement of agricultural implements began before 1917 and is being actively carried on now.

Apart from the town of Smolensk (*q.v.*) there is not much factory industry, the chief occupations of this type being flour-milling, saw-milling, oil-pressing and leather works. Matches are made at Vyazma and there are textile industries at Sychevka and Yartsevo. Apart from Roslavl, which has a population of 25,494, there is no large town other than Smolensk. Every variety of work dependent on the abundant timber supply is carried out amongst the peasants, including the preparation of tar and pitch, the making of wooden instruments, carriages, etc.

The province was important in early times as a link on the commercial route between Constantinople and the north. Later its position on the west made it the arena of struggles between Lithuania, Russia and Poland. The region suffered severely during the French invasion of 1812, and the peasants afterwards remained in dire poverty, partly due to the unequal distribution of pasture. Proximity to the disorders of the western front in 1914–20 added to the distress and the standard of life is poor. Many peasants seek seasonal additions to their income by migrating to other regions as navvies.

SMOLENSK, a town of Russia, the administrative centre of the province of Smolensk, situated on the Dnieper river, in 54° 50′ N., 32° 5′ E., at a point where the plateau is deeply entrenched and approaches the river both on the north and south. The ancient *kreml* or fortress was built on high crags on the left bank during the reign of Boris Godunov (1598–1605), but is now in ruins. The

town has developed owing to its position as a railway junction for five lines. Its industries include copper and iron smelting, the making of machinery for the textile industries, saw-milling, the manufacture of wooden goods, brick and pottery making and brewing. Pop. (1926) 71,177. Since the revolution a university has been created in the town, which had previously several scientific societies and museums and three public libraries. Its cathedral was built in 1676–1772 on the site of a building dating from 1101 and destroyed in 1611 during a siege by the Poles. The town has a monument commemorating the Russian musical composer M. I. Glinka (1885).

Smolensk is one of the oldest towns of Russia, and is mentioned in Nestor's *Chronicle* as the chief town of the Slav tribe of the Krivichis, situated on the great commercial route "from the Varyaghs to the Greeks." It maintained a lively traffic with Constantinople down to the 11th century, when the principality of Smolensk included Vitebsk, Moscow, Kaluga and parts of the present government of Pskov. The princes of Kiev were often recognized as military chiefs by the *vyeche* (council) of Smolensk, who mostly preferred Mstislav and his descendants, and Rostislav, son of Mstislav, became the ancestor of a series of nearly independent princes of Smolensk. From the 14th century these fell under the influence of the Lithuanian rulers, and in 1408 Smolensk was annexed to Lithuania. In 1449 the Moscow princes renounced their claims upon Smolensk; nevertheless this important city, with nearly 100,000 inhabitants, was a constant source of contention between Moscow and Lithuania. In 1514 it fell under Russian dominion; but during the disturbance of 1611 it was taken by Sigismund III. of Poland, and it remained under Polish rule until 1654, when the Russians retook it. In 1686 it was definitely annexed to Russia. In the 18th century it played an important part as a basis for the military operations of Peter the Great during his wars with Sweden. In 1812 it was well fortified; but the French, after a two days' battle, defeated the Russians here and took the city, when it suffered much.

SMOLLET: *see* Salmon.

SMOLLETT, TOBIAS GEORGE (1721–1771), British novelist, was born in Dalquhurn, Dumbartonshire. His father Archibald (youngest son of Sir James, the laird of Bonhill, a zealous Whig judge and promoter of the Union of 1707) died in 1723. Tobias was sent to Dumbarton school, and, after qualifying for a learned profession at Glasgow university, was apprenticed in 1736 to a surgeon in that city. At the age of eighteen he crossed the border to conquer England with a tragedy, *The Regicide,* based on Buchanan's description of the death of James I.

The story of the journey is told in the early chapters of *Roderick Random.* The failure of the play—certainly the worst thing he ever wrote—became the stock grievance of Smollett's life. No one would read it, and he would have starved had he not secured a position as surgeon's mate on H.M.S. "Cumberland," and served during the whole of the siege of Cartagena in 1741. The fleet returned to Jamaica, where Smollett fell in love with the daughter of a planter, Nancy Lascelles, whom he married on returning to England. He set up as a surgeon in Downing street, but with little success, and he soon began to devote his attention to writing fiction. His first novel *Roderick Random* (1748) recounts a life of varied adventure in the company of a servant. The author draws on his adventures on the English highway and in the cockpit of a king's ship, revealing the seaman to such purpose that, as Scott says, every one who has written about the navy since seems to have copied more from Smollett than from nature. There was no author's name on the title of the two small volumes of *Random;* it was actually translated into French as being by Fielding. But Smollett went to Paris to ratify his fame, and published his derelict play as "by the author of *Roderick Random.*"

Smollett still designed to combine medicine with authorship, for in June 1750 he obtained the degree of M.D.; and after a visit to Paris published in 1751 his second novel, *The Adventures of Peregrine Pickle,* which was a resounding success, both in England and France. It is no exaggeration to say that the tideway of subsequent fiction is strewn on every hand with the *dissecta membra* of Smollett's happy phrases and farcical inventions; but this novel is marred to an even greater extent by interpolations and personal attacks than its predecessor. His third novel, *Ferdinand Count Fathom,* appeared in 1753, by which time the author, after a final trial at Bath, had abandoned medicine for letters, and had settled down at Monmouth House, Chelsea. The squalor and irony of the piece repel the reader, but it is Smollett's greatest feat of invention, and was the model of all the mystery and terror school of fiction commencing with Radcliffe and Lewis. It was not particularly remunerative, and his expenses seem always to have been profuse. He was a great frequenter of taverns and entertained largely.

To sustain these expenses Smollett organized big and saleable "standard" works for the booksellers, contracting them out to his "myrmidons." He edited *Don Quixote,* a new literary periodical the *Critical* (Feb. 1756) by way of corrective to Griffith's *Monthly Review,* and organized a standard library *History of England,* and a seven-volume compendium of *Voyages,* for which he wrote a special narrative of the siege of Cartagena. In 1758 he projected and partly wrote a vast *Universal History,* and in January 1760 he brought out the first number of a new sixpenny magazine, the *British,* to which he contributed a serial, the mediocre *Adventures of Sir Launcelot Greaves.* By these Herculean labours as a compiler Smollett must have amassed a considerable sum. For the extravaganza, *The Reprisal, or the Tars of Old England* he received £200. In 1762 Smollett edited the *Briton.* He had already been ridiculed, insulted, fined and imprisoned in the Marshalsea. He was now to support the North British favourite of George III. in the press, not we may reasonably suppose without substantial reward. Yet after incurring all this unpopularity, Smollett was thrown over by his chief, Lord Bute, on the ground that his paper did more to invite attack than to repel it.

The *Briton* expired in February 1763, and again Smollett undertook such tasks as a universal gazetteer and a translation of Voltaire in 38 volumes. In April, however, his only daughter died at the age of fifteen, and, over-wrought from sedentary strain, he followed the advice of his wife and made two years' sojourn abroad, mainly upon the Riviera, which Smollett turned to such excellent purpose in his *Travels* (1766), remarkable alike for their acidity and for their insight. On his arrival from Italy, where he had provided material for Sterne's portrait of the distressful "Smelfungus," Smollett seemed to be getting over his pulmonic complaint. But his health was thoroughly undermined, and a neglected ulcer helped to sap his strength. He resolved on a summer journey to Scotland, and when he proceeded to Bath in 1766 his complaint at last took a turn for the better.

In 1768 he was again in London, and with a return of his vital energy came a recrudescence of the old savagery. *The History and Adventures of an Atom* is a clever, but coarse Rabelaisian satire upon the conduct of public affairs in England from the Seven Years' War to the date of publication. He lashes out on all sides without fear or favour. In 1769 he settled at Pisa and then near Antignano, near Leghorn, where during the autumn of 1770, he wrote *Humphrey Clinker,* in the form of itinerant letters. The character drawing, though still caustic, seems riper and more matured. He died at Leghorn on Sept. 17, 1771, and was buried there in the old English cemetery.

The chief collective editions are as follows: 6 vols., Edinburgh, 1790; 6 vols., London, 1796, with R. Anderson's Memoir; *Works,* ed. J. Moore, 1797 (re-edited J. P. Browne, 8 vols., 1872); *Works,* ed. Henley and Seccombe (12 vols., 1899–1902). To which must be added a one-volume *Miscellaneous Works,* ed. Thomas Roscoe (1841); *Selected Works* (with a life by David Herbert) (Edinburgh, 1870); Ballantyne's edition of the Novels with Scott's memoir (2 vols., 1821); and G. Saintsbury's edition of the Novels (12 vols., 1895). There are Lives by Robert Chambers (1867), David Hannay (1887) and O. Smeaton (1897). Additional information of recent date will be found in the article on Smollett in the *Dict. Nat. Biog.,* Masson's *British Novelists,* H. Graham's *Scottish Men of Letters in the Eighteenth Century, Blackwood's Mag.* for May 1900; and the introduction to Smollett's *Travels through France and Italy* (World's Classics, 1907). *See* also H. S. Buck, *A Study in Smollett, Chiefly Peregrine Pickle* (New Haven, 1925); L. Melville, *Life and Letters of Tobias Smollett, 1721–71* (1926); H. S. Buck, *Smollett as Poet* (1927).

SMOOT, REED (1862–), American senator, was born at Salt Lake City, Utah, on Jan. 10, 1862. He was educated at Deseret university and at the Brigham Young academy, Provo, Utah. He amassed considerable wealth as a banker and woollen manufacturer. In 1895 he was appointed one of the presidents of the Utah Stake of the Church of Jesus Christ of Latter Day Saints (Mormon), and in 1900 was made an apostle. He was elected to the U.S. Senate from Utah in 1902. Attempts were made to prevent his entering the Senate because of his connection with the Mormon Church and on the charge that he personally favoured polygamy and was a polygamist. He was allowed to take his seat; but the matter was referred to the Senate committee on privileges and elections for investigation.

In June 1906 the committee by a vote of seven to five recommended that he be unseated; but, as the personal charges against him had not been proved, the Senate in Feb. 1907, by a vote of 42 to 23, refused to remove him. He was re-elected in 1908, 1914, 1920, and 1926. In 1919 Smoot opposed participation by the United States in the League of Nations. Later he served as chairman of the finance committee of the Senate, was a member of the World War Foreign Debt Commission, a regent of the Smithsonian Institution, an elector of the New York Hall of Fame, and chairman of the public buildings commission, directing the Government building programme at Washington (D.C.), begun in 1927.

SMUGGLING, a breach of the revenue laws either by the importation or the exportation of prohibited goods or by the evasion of customs duties on goods liable to duty. Legislation on the subject in England has been very active from the 14th century downwards. In the reign of Edward III. the illicit introduction of base coin from abroad led to the provision of the Statute of Treasons 1351, making it treason to import counterfeit money as the money called "Lushburgh." Such importation is still an offence, though no longer treason. After the Statute of Treasons a vast number of acts dealing with smuggling were passed, most of which will be found recited in the repealing act of 1825. The smuggler of the 18th century finds an apologist in Adam Smith, who writes of him as "a person who, though no doubt highly blamable for violating the laws of his country, is frequently incapable of violating those of natural justice, and would have been in every respect an excellent citizen had not the laws of his country made that a crime which nature never meant to be so." The gradual reduction of duties (begun by Pitt) brought smuggling in the United Kingdom into insignificance until the revival of import duties after the World War led to frequent offence. In 1926–27 out of 8,246 seizures of smuggled goods, 5,967 related to tobacco and spirits. Most of the existing legislation on the subject of smuggling is contained in the Customs Consolidation Act 1876.

The main provisions are as follows. Vessels engaged in smuggling are liable to forfeiture and their owners and masters to a penalty not exceeding £500. Smuggled and prohibited goods are liable to forfeiture. Officers of customs have a right of search of vessels and persons. Fraudulent evasion or attempted evasion of customs duties renders the offender subject to forfeit either treble the value of the goods or £100 at the election of the commissioners of customs. Heavy penalties are incurred by resistance to officers of customs, rescue of persons or goods, assembling to run goods, signalling smuggling vessels, shooting at vessels, boats or officers of the naval or revenue service, cutting adrift customs vessels, offering goods for sale under pretence of being smuggled, etc. Penalties may be recovered either by action or information in the superior courts or by summary proceedings. In criminal proceedings the defendant is competent and compellable to give evidence. The Merchant Shipping Act 1894 makes any seaman or apprentice, after conviction for smuggling whereby loss or damage is caused to the master or owner of a ship, liable to pay to such master or owner such a sum as is sufficient to reimburse the master or owner for such loss or damage, and the whole or a proportional part of his wages may be retained in satisfaction of this liability. Additional provisions as to smuggling are also contained in the Customs and Inland Revenue Act 1879, and the Customs and Inland Revenue Act 1881. A smuggling contract is generally illegal. But it may be valid, and the vendor may recover the price of goods, even though he knew the buyer intended them to be smuggled, unless he actually aids in the smuggling so as to become *particeps criminis*. Contracts to defraud the revenue of a foreign state are, according to English decisions, not illegal. There is a German decision, more consonant with international morality, to the opposite effect.

The penalities for smuggling in the United States will be found mainly in tit. xxxiv. ch. 10 of the Revised Statutes. The seaman guilty of smuggling is liable to the same penalty as in England, and in addition to imprisonment for twelve months, s. 4596.

See Stephen Dowell's *History of Taxation* (2nd ed., 1888), and Luke Owen Pike's *History of Crime in England* (1873–76); and for general accounts of smuggling *see* W. D. Chester, *Chronicles of the Customs Department* (1885); H. N. Shore, *Smuggling Days and Smuggling Ways* (1892); Atton and Holland, *The King's Customs* (1908); C. G. Harper, *The Smuggler: Picturesque Chapters in the Story of an Ancient Craft* (1909).

SMUT AND BUNT, in botany and agriculture, the names given to species of fungi attacking various flowering plants, especially cereals and other grasses. The name smut refers to the black, dust-like masses of spores which appear in the flowers of the corn and are the only part of the parasite visible externally. Smuts and bunts comprise the group Ustilagineae of the Basidiomycetes. Bunts, often called, especially in America, stinking smuts, on account of their unpleasant fishy smell, are exemplified by the bunts of wheat (*Tilletia foetens; T. tritici*). Smuts, differentiated from stinking smuts as "loose" and "covered" smuts, attack only the inflorescence, which they destroy entirely. The most important genus is *Ustilaga,* species of which attack oats, barley, wheat, maize, etc. The bunts enter the tissues of the host when the latter is a seedling and their mycelia ramify throughout the plant. Spores appear only in the flowers of the cereal, however, and the parasite destroys the centres of the corn-grains.

Smuts of barley (*Ustilaga hordei*) and the bunts of wheat can largely be kept under by soaking the seed before sowing in a solution of copper sulphate (1 lb. to 25 gal. of water) for 12 hours. Soaking in formalin solution (1 lb. to 50 gal. of water) is also effective against these diseases and against smut of oats (*U. avenae*). Neither of these, however, is of any avail against maize smut (*U. maydis*) and no effectual preliminary treatment is as yet known for this parasite. *See* FUNGI. For their grave economic effects, *see,* also, WHEAT, BARLEY, etc.

SMUTS, JAN CHRISTIAAN (1870–), South African statesman and general, was born on May 24, 1870 near Riebeek West, Malmesbury district, Cape Colony, the son of J. A. Smuts and Catharina de Vries. In 1886 he commenced his studies at Stellenbosch, and in 1891 went to Cambridge, where his career was brilliant. In 1895 he was admitted to the Cape Town bar. In Oct. 1895 his first political speech was delivered at Kimberley, where, as a result of the understanding between Jan Hofmeyr and Rhodes, he defended the latter's policy. The Jameson Raid (Jan. 1896), changed the whole complexion of South African politics. Smuts ranged himself on the side of the Transvaal, and shortly afterwards joined the Bar at Johannesburg. In 1898, though two years under the legal age, he was made state attorney by President Kruger, and took part in the negotiations with the British agent at Pretoria on the franchise. He accompanied Kruger to the abortive conference with Milner at Bloemfontein in July 1899.

In the early stages of the Boer War, Smuts was employed in legal and organising work, but on the occupation of Pretoria, in 1900, he joined the Boer field forces. From the Eastern Transvaal, where his Government was hard pushed, he made his way to the West, where he fought under De la Rey. Subsequently he acted as commander-in-chief of the Boer and Cape rebel commandoes in the Cape. He was besieging a mining camp in Namaqualand, when Botha sent for him to take part in the peace negotiations at Vereeniging (1902). He threw in his weight on the side of those who urged a compromise, as against the intransigent commandants.

After peace, Smuts became a strong and active protagonist of

Botha's policy—loyalty to the new order, and racial conciliation. Practising as a barrister at Pretoria, he spent a good deal of time in the reconstruction of the remnants of the Boer nation and together with Botha and other leaders he met Joseph Chamberlain at Pretoria. The Boers, supported by part of the British population, strongly opposed several points in Milner's policy, *e.g.*, the importation of Chinese coolies for the gold mines, and Smuts was among those who refused Milner's offer of seats in the nominated Legislative Council.

Het Volk.—In 1904 Botha and Smuts founded the political organisation open to both races known as "Het Volk." Early in 1906 Smuts visited London, where he worked for fully responsible government in the Transvaal and Orange Free State, which was granted in 1906. Early in 1907 elections for the Assembly were held. Smuts took a prominent part and was returned unopposed for Wonderboom (Pretoria). As colonial secretary, under Botha, he became the driving force of the Cabinet. In May 1908 Smuts openly declared for the union of the South African colonies. In October of that year, the National Convention, which eventually produced the South African Act, began its work. Smuts was one of the makers of the Act. In May 1910 Union was consummated. Smuts was elected member of the legislative assembly for Pretoria West, and became minister of the interior, mines and defence. In 1911 the South African party was founded at Bloemfontein, where Smuts foreshadowed the political difficulties ahead. Early in 1912 he introduced his Defence bill, which powerfully affected the future of South Africa. A little later Smuts took over the treasury, retaining the portfolio of defence. During the Hertzog crisis, at the end of 1912, he did his utmost to prevent a split, but once the fateful step had been taken, he resolutely supported Botha. In July 1913 a revolutionary strike shook the Rand to its foundations. Botha and Smuts, at great personal risk (and unescorted) saved the situation at Johannesburg, after Lord Gladstone had sanctioned the use of Imperial troops to quell disturbances. In Jan. 1914 an attempted general strike was nipped in the bud by Smuts, who in record time rushed up the commandoes but recently organised under his Defence Act. The deportation of nine strike leaders on the S.S. "Umgeni," though authorised by the Cabinet, has been chiefly debited to Smuts by his opponents. A double Indemnity bill, covering the two revolts, led to a violent and protracted parliamentary debate.

The World War.—The outbreak of the World War shifted the South African centre of gravity to Smuts' office. In Sept. 1914, when Beyers resigned as Commandant-General in the midst of the preparations for a campaign against the Germans in South-west Africa, Smuts assumed his functions. The rebellion of De Wet, Maritz, Beyers and others followed. This was suppressed by Botha, acting in the closest collaboration with Smuts at headquarters. In 1915, after a visit to Botha's forces in South-west Africa, Smuts took the leading part in the general election, which was marked by extreme bitterness. He was re-elected for Pretoria West by a narrow majority. Early in 1916 he refused the command offered him in East Africa by the Imperial Government, but shortly afterwards yielded to representations. For the success of his operations against Lettow-Vorbeck *see* EAST AFRICA, OPERATIONS IN.

Work in London.—In March 1917 Smuts arrived in London to represent South Africa at the Imperial War conference, and was sworn as a privy councillor. After the conference, at a dinner given in recognition of his war services, by members of both Houses of Parliament, he made his famous declaration on the British Commonwealth of Nations. He accepted a seat in the War Cabinet, taking a deep interest in the flying services, and his proposals for their unification were accepted by the Cabinet. Incidentally, he supervised London's air defences. He suggested, and became chairman of, the War Priorities Committee, which settled priority of claims among departments concerned in the war, and allocated man-power and other resources. Occasionally he visited the Western front, where he conferred with commanders. In Dec. 1917 Smuts met Count Mensdorff at Geneva, and explored the possibility of a separate peace with Austria; but was finally convinced that it was not possible. The following Feb. he spent with Allenby in Palestine, working out plans for a great advance.

After the Armistice, Smuts wrote his Memorandum on the League of Nations, *The League of Nations: A Practical Suggestion* (1918), which received the support of both President Wilson and Mr. Lloyd George, and in substance became the Covenant of the League. With Botha, he represented South Africa at the Peace Conference, where he was mainly concerned with the Covenant and Dominion status. At this time he undertook a mission to Vienna and to Budapest, where the Communist Government had violated the Armistice.

South African Politics.—After the conference, he returned to South Africa. In Aug. 1919, he became prime minister of the Union (in succession to Botha). During this period he twice attended the Imperial Conference. In 1921 his visit was notable for the part he played in securing peace in Ireland. During the Conference of 1923 (held while the Ruhr crisis was at its worst), he advocated a fresh attempt to settle the European situation. The suggestion was generally approved, and it helped to prepare the way for the Dawes Commission.

In 1920, repeated attempts to reunite the South African party and the Nationalists failed. The Unionists, under Smartt, decided to dissolve their organisation and to join the South African party. The consequences of this fusion lost Smuts a certain amount of support among both English and Dutch. A general election, held on that issue, left him, however, with a working majority, and the combined party did fairly well in Parliament. In 1922, however, another workers' revolt on the Rand (which had to be suppressed by the military and burghers, after the exercise of considerable patience) led to a junction of forces between advanced Nationalists and the Labour element. By-elections went against the Government, and a formal pact was made by the two Opposition parties. In 1924, after a crucial by-election, Gen. Smuts took the country by surprise; he dissolved Parliament, realising that the people were probably dissatisfied with him. The result, nationally considered, thoroughly bore out the wisdom of his decision, for the South African party was heavily defeated. Hertzog did not obtain a clear majority, but was able with the assistance of Labour to form a coalition Cabinet. Although Smuts himself lost Pretoria West, he was elected unopposed for Standerton, Botha's old constituency.

As Opposition leader, he continued to pay close attention to affairs of state, while indulging to some extent his fondness for philosophy and botany. In 1925 he delivered the opening address, as president of the S.A. Association for the Advancement of Science. In 1926 General Smuts published *Holism and Evolution*, a philosophical treatise; and in 1930 *Africa and Some World Problems*. He visited the U. S. and Canada in January 1930. (N. LE.; X.)

SMYBERT or **SMIBERT, JOHN** (1684–1751), Scottish American painter, was born at Edinburgh in 1684, and died in Boston (Mass.), in 1751. He studied under Sir James Thornhill, and in 1728 accompanied Bishop Berkeley to America with the intention of becoming professor of fine arts in the college which Berkeley was planning to found in Bermuda. The college, however, was never established, and Smybert settled in Boston, where he married in 1730. In 1731 he painted "Bishop Berkeley and His Family," now in the dining-hall, Yale university, a group of eight figures. He painted portraits of Jonathan Edwards and Judge Edmund Quincy (in the Boston art museum), Mrs. Smybert, Peter Faneuil, and Governor John Endecott (in the Massachusetts historical society), John Lovell (memorial hall, Harvard university), and probably one of Sir William Pepperrell; and examples of his work are owned by Harvard and Yale universities, by Bowdoin college, by the Massachusetts historical society, and by the New England historical and genealogical society.

SMYRNA (*Ismir*), in ancient times one of the most important and now by far the greatest of the cities of Asia Minor, has preserved an unbroken continuity of record and identity of name from the dawn of history to the present time.

1. **The Ancient City.**—It is said to have been a Lelegian city before the Greek colonists settled in Asia Minor. The name, which is said to be derived from an Amazon called Smyrna, is indubitably Anatolian, having been applied also to a quarter of Ephesus, and (under the cognate form Myrina) to a city of Aeolis, and to a tumulus in the Troad. The Aeolic settlers of Lesbos and Cyme, pushing eastwards by Larissa and Neonteichos and over the Hermus, seized the valley of Smyrna. It was the frontier city between Aeolis on the north and Ionia on the south, and was more accessible on the south and east than on the north and west. By virtue of its situation it was necessarily a commercial city, like the Ionian colonies. It is therefore not surprising that the Aeolic element grew weaker; strangers or refugees from the Ionian Colophon settled in the city, and finally Smyrna passed into the hands of the Colophonians and became the thirteenth of the Ionian states. The change had taken place before 688, when the Ionian Onomastus of Smyrna won the boxing prize at Olympia, but it was probably then a recent event. The Colophonian conquest is mentioned by Mimnermus (before 600 B.C.), who counts himself equally a Colophonian and a Smyrnaean. The Aeolic form of the name, Σμύρνα, was retained even in the Attic dialect, and the epithet "Aeolian Smyrna" remained long after the conquest. The situation of Smyrna on the path of commerce between Lydia and the west raised it during the 7th century to the height of power and splendour. It lay at the head of an arm of the sea, which reached far inland and admitted the Greek trading ships into the heart of Lydia. One of the great trade routes which cross Anatolia descends the Hermus valley past Sardis, and then diverging from the valley passes south of Mt. Sipylus and crosses a low pass into the little valley, about 7 m. long and 2 broad, where Smyrna lies between the mountains and the sea.

When the Mermnad kings raised the Lydian power and aggressiveness Smyrna was one of the first points of attack. Gyges (*c.* 687–652) was, however, defeated on the banks of the Hermus; the situation of the battlefield shows that the power of Smyrna extended far to the east and probably included the valley of Nymphi (Nif). A strong fortress, the ruins of whose ancient and massive walls are still imposing, on a hill in the pass between Smyrna and Nymphi, was probably built by the Smyrnaean Ionians to command the valley of Nymphi. According to Theognis (about 500 B.C.), "pride destroyed Smyrna." Mimnermus laments the degeneracy of the citizens of his day, who could no longer stem the Lydian advance. Finally, Alyattes III. (609–560) conquered the city, and Smyrna for 300 years lost its place in the list of Greek cities. It did not cease to exist, but the Greek life and political unity were destroyed, and the Smyrnaean state was organized on the village system (ᾤκεῖτο κωμηδόν.) It is mentioned in a fragment of Pindar, about 500 B.C., and in an inscription of 388 B.C. A small fortification of early style, rudely but massively built, on the lowest slope of a hill N. of Burnabat, is perhaps a fortified village of this period. Alexander the Great conceived the idea of restoring the Greek city; the two Nemeses who were worshipped at Smyrna are said to have suggested the idea to him in a dream. The scheme was, according to Strabo, carried out by Antigonus (316–301), and Lysimachus enlarged and fortified the city (301–281). The acropolis of the ancient city had been on a steep peak about 1,250 ft. high, which overhangs the north-east extremity of the gulf; its ruins still exist, probably in much the same condition as they were left by Alyattes. The later city was founded on the modern site partly on the slopes of a rounded hill called Pagus near the south-east end of the gulf, partly on the low ground between the hill and the sea.

The "crown of Smyrna" seems to have been an epithet applied to the acropolis with its circle of buildings. Smyrna is shut in on the west by a hill now called Deirmen Tepe, with the ruins of a temple on the summit. The walls of Lysimachus crossed the summit of this hill, and the acropolis occupied the top of Pagus. Between the two the road from Ephesus entered the city by the "Ephesian gate," near which was a gymnasium. Closer to the acropolis the outline of the stadium is still visible, and the theatre was situated on the north slopes of Pagus. The line of the walls on the east side is unknown; but they certainly embraced a greater area than is included by the Byzantine wall, which ascends the castle hill (Pagus) from the Basmakhanē railway station. Smyrna possessed two harbours—the outer, which was simply the open roadstead of the gulf, and the inner, which was a small basin, with a narrow entrance closed by a rope in case of need, about the place now occupied by bazaars. The inner harbour was partially filled up by Timur in 1402, but it had not entirely disappeared till the beginning of the 19th century. The modern quay has encroached considerably on the sea, and the coast-line of the Greek time was about 90 yd. farther south. The streets were broad, well paved and laid out at right angles; many were named after temples: the main street, called the Golden, ran across the city from west to east, beginning probably from the temple of Zeus Akraios on the west side of Pagus, and running round the lower slopes of Pagus (like a necklace on the statue, to use the favourite terms of Aristides the orator) towards Tepejik outside the city on the east, where probably the temple of Cybele, the Metroön, stood. Cybele, worshipped under the name of Meter Sipylene, from Mt. Sipylus, which bounds the Smyrna valley on the north, was the tutelar goddess of the city. The plain towards the sea was too low to be properly drained and hence in rainy weather the streets were deep with mud and water.

The river Meles, which flowed by Smyrna, is famous in literature and was worshipped in the valley. The most common and consistent tradition connects Homer with the valley of Smyrna and the banks of the Meles; his figure was one of the stock types on Smyrnaean coins, one class of which was called Homerian; the epithet "Melesigenes" was applied to him; the cave where he was wont to compose his poems was shown near the source of the river; his temple, the Homereum, stood on its banks. The steady equable flow of the Meles, alike in summer and winter, and its short course, beginning and ending near the city, are celebrated by Aristides and Himerius. The description applies admirably to the stream which rises from abundant fountains, now known as Diana's bath, east of the city, and flows into the south-east extremity of the gulf. The belief that the torrent, almost dry except after rains, which flows by Caravan bridge, is the ancient Meles, flatly contradicts the ancient descriptions.

In the Roman period Smyrna was the seat of a *conventus* which included south Aeolis and a great part of the Hermus valley. It vied with Ephesus and Pergamum for the title "First (city) of Asia." A Christian church existed here from a very early time, having its origin in the considerable Jewish colony. Polycarp was bishop of Smyrna and was martyred there A.D. 155. The bishops of Smyrna were originally subject to the metropolitan of Ephesus; afterwards they became independent (αὐτοκέφαλοι), and finally were honoured with metropolitan rank.

When Constantinople became the seat of government the trade between Anatolia and the west lost in importance, and Smyrna declined apace. A Turkish freebooter named Tsacha seized Smyrna in 1084, but it was recovered by the generals of Alexius Comnenus. The city was several times ravaged by the Turks, and had become quite ruinous when the emperor John Ducas Vatatzes about 1222 rebuilt it. But Ibn Batuta found it still in great part a ruin when the famous chieftain Aidin had conquered it about 1330 and made his son Amur governor. It became the port of the Aidin amirate. Soon afterwards the Knights of Saint John established themselves in the town, but failed to conquer the citadel. In 1402 Timur stormed the town and massacred almost all the inhabitants. The Mongol conquest was only temporary, but Smyrna was resumed by the Seljuks of Aidin and has remained till the present day in Mohammedan hands. Until the reign of Abdul Mejid it was included for administrative purposes in the *eyalet* of Jezair (the Isles) and not in that of Anatolia. The representative of the Capitan Pasha, who governed that *eyalet*, was, however, less influential in the city than the head of the Kara Osman Oglu's of Manisa. (*See* MANISA.) From the early 17th century till 1825, Smyrna was the chief provincial factory

of the British Turkey Company, as well as of French, Dutch and other trading corporations. (W. M. RA.; D. G. H.)

2. **The Modern City,** capital of the Aidin vilayet, and the most important town of Asia Minor. Pop. (1927), 190,291. It is one of the principal ports of the Turkish republic, and has a large trade, of which the greater part is with Great Britain. The chief items of export are figs, tobacco, valonia, carpets, raisins and silk. Until 1894 the two railways from Smyrna to the interior belonged to British companies; but in 1897 the Smyrna-Alashehr line passed into the hands of a French syndicate, which completed an extension to Afium Kara-hissar and virtually (though not actually) effected a junction with the Anatolian railway system. This line has branches to Burnabat and Soma. The Smyrna-Aidin line has been extended to Egerdir. It has branches to Buja, Seidikeui, Tireh, Odemish, Sokia, Denizli and Ishekli.

See general authorities for *Asia Minor,* especially the travellers, almost all of whom describe Smyrna. Also B. F. Slaars, *Étude sur Smyrne* (1868); and W. M. Ramsay, *Letters to the Seven Churches* (1904) and article in Hastings's *Dict. of the Bible* (1902).

POST-WAR DEVELOPMENTS

At the Peace Conference which was held in 1919 Greece put forward a claim to the Smyrna area, assigned it was understood to Italy by the Agreement of St. Jean de Maurienne (April 17, 1917)—an agreement which remained unratified owing to Russian objections. M. Venizelos argued on the Greek claim before the Council of Ten on Feb. 3–4, 1919. The final decision of the Council of Three, authorising the Greeks to occupy Smyrna, was taken apparently without the knowledge of the Italians, who had withdrawn temporarily from the conference, or of the American expert advisers to President Wilson. The occupation was in theory an Allied occupation, but was generally taken to mean acceptance of the Greek claims. Greek troops occupied Smyrna on May 15, 1919. The first entry of the Greeks was marked by atrocities against the Turkish population.

Under the Treaty of Sèvres, Aug. 10, 1920, it was stipulated that the town of Smyrna and the Ionian hinterland were to be under Greek administration for five years. The Greek claim was based on ethnographical grounds. Reliable racial statistics for the area were not available, but an American computation of 1914 gave the total population as 1,057,000, including 509,000 Turks, 470,000 Greeks and 78,000 others.

Turkish forces under Mustafa Kemal and the Greeks were soon engaged in hostilities, in which at first the Greeks were successful. Mustafa Kemal, however, continued to consolidate his position in Turkey, while the fall of Venizelos (Nov. 1920) and the return of King Constantine to Greece (*see* GREECE) weakened the sympathies which Greece had enjoyed in Great Britain, her chief supporter among the Allied Powers. Negotiations at the London and Paris conferences (1921 and 1922) having failed, the Kemalists drove back the Greek army, which with many thousands of Greek refugees from all parts of Asia Minor embarked hurriedly and left Smyrna, which the Turks entered on Sept. 9, 1922. Under the Treaty of Lausanne (July 24, 1923) Smyrna and the surrounding zone reverted under full Turkish sovereignty.

Meanwhile, the town and district had suffered frightfully under the atrocities of both belligerents, and these sufferings culminated when, a few days after the Turkish entry into the town, fire broke out in the Armenian quarter. Only the wretched Turkish quarter on Mount Pagus was untouched, and more than three-fifths of the city was destroyed, including all the banks, business houses and consulates in the European quarter on the quay. The loss of life was impossible to compute. In April 1928 Smyrna again suffered serious damage by earthquake.

SMYTH, DAME ETHEL MARY (1858–), D.B.E. (1922), British composer, was born in London April 23, 1858, the daughter of Gen. J. H. Smyth. She studied music at Leipzig under Heinrich von Herzogenberg. She produced her first opera *Fantasio* at Weimar in 1898, others being given at Leipzig, Prague and Vienna. Her first opera to be produced in London was *Der Wald,* given at Covent Garden in 1902 which was followed by *The Wreckers* (1909), a vividly romantic work. Her *Mass in D,* first performed in 1893, was revived 30 years later. *The Boatswain's Mate,* a comic opera, was produced in 1916. Dr. Ethel Smyth took a prominent part in the militant suffragist movement, and composed *The March of the Women* (1911) the battle song of the W.S.P.U. Her compositions include *Fête Galante* (1923) and *Entente Cordiale,* 1924, operas; also chamber music, choruses and songs, all characterised by energy of invention, exuberant vitality and clever workmanship. *See* her brilliant memoirs *Impressions that Remained* (1919, new ed. 1923), *Streaks of Life* (1921, new ed. 1924). *A Three-Legged Tour in Greece* (1927) and *A Final Burning of Boats* (1928).

See also R. A. Streatfeild, *Une Musicienne Anglaise: Ethel Smyth* (1912).

SMYTH, HERBERT WEIR (1857–), American classical scholar, was born at Wilmington, Del., on Aug. 8, 1857. He was educated at Swarthmore (A.B., 1876), Harvard (A.B., 1878), and Göttingen (Ph.D., 1884). During 1884–85 he was instructor in Greek and Sanskrit at Williams college, and then for two years was reader in Greek at Johns Hopkins university. From 1888 to 1901 he was professor of Greek at Bryn Mawr. In the latter year he was appointed professor of Greek literature at Harvard, becoming emeritus in 1925. During 1899–1900 he was professor at the American Classical school at Athens. From 1889 to 1904 he was secretary of the American Philological Association and editor of its *Transactions,* and in 1904 was elected president. His works include a treatise on the Ionic dialect (1894); *Greek Melic Poets* (1900); *Greek Grammar for Colleges* (1916); *Aeschylus,* text and translation (1922–26), in the "Loeb Classical Library"; and *Aeschylean Tragedy* (1924).

SMYTH (or SMITH), **JOHN** (*c.* 1570–1612), English nonconformist divine, commonly called the Se-baptist, was born about 1570, and was educated at Christ's college, Cambridge, where he proceeded M.A. in 1593. He was probably vicar of Hutton Cranswicke in the E. Riding of Yorkshire from 1593 to 1600, when he was elected lecturer or preacher of the city of Lincoln, an office of which he was deprived in Oct. 1602. Becoming connected with the Separatist movement he joined the Gainsborough church, and became its pastor[1]. With Thomas Helwys, John Murton (or Morton) and others, he migrated to Amsterdam at the end of 1607 to escape religious persecution, and in that city practised as a physician, and became the leader of "the second English church." (*See* CONGREGATIONALISM.) Under Mennonite influence he became a Baptist (*see* BAPTISTS). But he and his company were then faced by the dilemma that their own infant baptism did not count, and Smyth solved the problem by first baptizing himself (hence the name Se-Baptist), probably by affusion, and then administering the rite to Helwys and the others. Afterwards they decided to join the Mennonites, who were suspicious of a man who had never held one position for long, and demanded a statement of doctrines, which he gave them in twenty articles written in Latin, and in *The Last Book of John Smyth, called the Retractation of his Errors,* together with a confession of faith in 100 Propositions. Smyth himself died of consumption in August 1612. Helwys and Morton returned to England, and established the first English Baptist churches.

See J. H. Shakespeare, *Baptist and Congregational Pioneers* (London, 1906); H. M. Dexter, *The England and Holland of the Pilgrims* (London and Boston, 1906). (A. J. G.; X.)

SMYTH (or SMITH), **WILLIAM** (c. 1460–1514), bishop of Lincoln, was a Lancashire man by birth, and probably passed some of his early days at Knowsley under the roof of Margaret, countess of Richmond and Derby, the mother of Henry VII. He appears to have been a member of Lincoln College, Oxford, and in 1485, just after the battle of Bosworth, he was made keeper of the hanaper of the chancery. Two of Edward IV.'s daughters were entrusted to his keeping; he was a member of the royal council and he obtained many rich preferments. In 1493 he became bishop of Coventry and Lichfield. The bishop was a member of Prince Arthur's council in the marches of Wales, and in 1501, five years after he had been translated to the bishopric of Lincoln, he became lord president of Wales. About 1507 he

[1]He was never vicar of Gainsborough, and must not be confused with the John Smyth who was imprisoned in the Marshalsea in 1592.

and Sir Richard Sutton (d. 1524) set to work to found a new college in Oxford. They rebuilt Brasenose Hall, added other existing halls to it, and having obtained a charter in 1512, called it *The King's haule and college of Brasennose*. Smyth, who was one of the executors of Henry VII.'s will, retired from public life just after this king's death; he was, however, president of Wales until his death at Buckden in Huntingdonshire on Jan. 2, 1514. In addition to his liberal gifts to Brasenose College he gave money or land to Lincoln and to Oriel Colleges; he founded a school at Farnworth, Lancashire, and he refounded the hospital of St. John at Lichfield. From 1500 to 1503 he was chancellor of Oxford University.

SNAIL, the name usually given to land molluscs of the class Gastropoda which have spiral shells, such as the common snail (*Helix aspersa*) and the wood snail (*Cepea nemoralis*). In Scotland both shell-bearing and shell-less land molluscs are known as "snails." Marine Gastropod molluscs are sometimes called "sea snails" and the freshwater gastropods (*Vivipara, Limnaea,* etc.) are known as "pond snails" and "river snails." The shell-bearing Gastropoda ("snails" in the wide sense) are a very large class of animals, embracing some 40,000 living and extinct species, with a world-wide distribution.

Perhaps the most striking feature in the structure of snails is their shell. In the majority this is spiral and consists of several whorls which have a right-handed (dextral) coil. A left-handed (sinistral) coil is found in certain forms, either as an occasional variation of normally dextral forms (*Limnaea pereger* and *Neptunea antiqua*) or as a fixed generic characteristic (*Physa, Clausilia*). Sometimes the shell is cup-shaped (*Patella*, the common limpet), tubular (*Coecum*) or plate-like (*Scutum*). In many land and marine Gastropods it becomes internal and degenerate or is eventually lost entirely, and a slug-like form is attained. The land snails belong, with some exceptions, to the order Pulmonata and a very large proportion of them are placed in the family *Helicidae,* which is one of the largest groups of land invertebrates. They are mainly animals of retiring habits living on green plants or on decaying vegetable debris, though a few (e.g., *Glandina, Streptaxis*) are carnivorous. As a rule, they are more frequently found upon calcareous soils and are certainly rare on "acid" formations. They usually live during the daytime buried out of sight under leaves and, as a certain amount of moisture is necessary for their well-being, they aestivate in hot and sunny weather in crevices or under ground, from which protection they emerge at night or during rain.

Including the "snail-slugs" (*Testacella*), there may be said to be 125 species of land and fresh, or brackish, water snails in the British Isles. The largest family (indeed, the largest in the phylum Mollusca) is the *Helicidae,* of which there are 22 species in Great Britain. Among the commonest forms are *Helix aspersa,* the common or speckled snail, *Cepea nemoralis* and *hortensis,* the wood and garden snails and *Limnaea peregra,* the common pond snail. Certain species (e.g., *Belgrandia marginata*), which are still living in continental Europe, are found in a fossil state in the British Isles. *Paludestrina jenkinsi,* the only mollusc at present known to reproduce itself parthenogenetically (without fertilization), is found very plentifully in Great Britain.

In North America there are very numerous species of freshwater and land snails. Among representatives of the former group are some 65 species of *Limnaea* and 25 species of *Planorbis*. Of the land snails important families are the *Pupillidae,* with 50 species; the *Zonitidae,* with 65 species; and the exceedingly numerous *Helicidae,* of which the exclusively American genus *Polygyra* alone contains 125 species. (Concerning the use of snails by man, *see* GASTROPODA.)

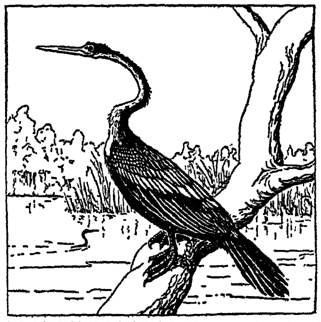
SNAKE-BIRD, or DARTER (*Anhinga anhinga*), a bird belonging to the same order as the cormorants (*q.v.*), to which they bear a resemblance both outwardly and in habits. They are, however, more slender in form and have neck and tail elongated. The pointed bill has its edges beset with backwardly-directed "teeth."

The male of the American species, which is often called the water-turkey, has a black plumage, glossed with green, with a white line on the neck and the bare skin of the head both green and orange, and white patches on the wings and tail. The bird haunts large rivers and lakes, frequently perching on overhanging branches or snags. It feeds on fish, which it chases and spears with its dagger-like bill, its agility under water is amazing. It often swims with only its head above water. The bird has been observed to play at catch with small twigs. The nest is built in a tree close to the water and is a large structure of sticks. The four eggs have white, chalky shells. Other species occur in Africa, Asia and Australia. All are characterised by the structure of the neck; the first seven neck vertebrae form a curve with its concavity forward; but the eighth articulates with the seventh nearly at right angles; the ninth is directed abruptly downwards and the rest form a gentle forward convexity. This mechanism permits great flexibility.



BY COURTESY OF THE ZOOLOGICAL SOCIETY OF LONDON
THE INDIAN SNAKE BIRD (PLOTUS ANHINGA)

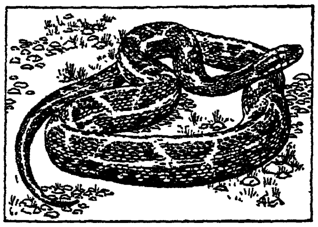
SNAKE-FLY, the name given to neuropterous insects of the genus *Raphidia,* closely allied to the alder-flies, remarkable for the elongation of the head and prothorax to form a neck and for the presence in the female of a long ovipositor. The larva is active, carnivorous, and terrestrial, and lives under loose bark of various trees. These insects are widely distributed, four species occuring in Britain.

SNAKE-ROOT. In most countries where snakes abound some root or herb is used by the natives as an antidote for the bites of venomous species, and many herbs have consequently received the name of snake-root. Botanically speaking, the name properly belongs to *Ophiorrhiza Mungos,* the Mungoose plant, a plant of the family Rubiaceae, used in the E. Indies for the purpose above indicated. In medicine, however, the roots of *Aristolochia Serpentaria, Polygala Senega* and *Cimicifuga racemosa* were understood by this name, being distinguished as the Virginian, seneca and black snake-roots. The root of *Aristolochia reticulata* is known in the United States as Red river or Texan snake-root.

The roots or rhizome of *Liatris spicata, Eryngium aquaticum* and *Eupatorium altissimum* have all been used in N. America for snake-bites, the first two being known as button snake-root and the last as white snake-root. The rhizome of *Asarum canadense* passes under the name of Canadian snake-root. All of these contain acrid or aromatic principles which, when a warm decoction of the drug is taken, exercise a powerfully diaphoretic or, in some cases, diuretic action, to which the benefit, if any, derived from their use must be attributed.

SNAKES, an order (*Ophidia*) in the class of REPTILES (*q.v.*). They are elongate animals without limbs, or with but claw-like rudiments of the hinder pair; without eyelids or external ears, with pointed re-curved teeth fused to the supporting bones, with a forked slender tongue which can be withdrawn into a sheath at its base, and, as a rule, with the two halves of the lower jaw not fused but joined by an elastic ligament. Like the lizards, with which they have many affinities, they are one of the dominant groups of reptiles of the present day and at least 2,000 different species are known. Their distribution is cosmopolitan with the exception of New Zealand, Ireland and some of the more recent, completely isolated, oceanic islands such as the Azores; as in other groups of terrestrial, cold-blooded animals the area of permanently frozen subsoil limits their northern and southern range and the greatest profusion of species and individuals is to be found in the tropics.

In the loss of limbs and the absence of well-differentiated neck, body and tail they may be regarded as degenerate and, by analogy with certain groups of limbless lizards, it seems probable that this type of bodily form arose in correlation with a habitat amongst dense vegetation; under these conditions limbs do not appear to be such efficient organs of locomotion as the lateral undulations which form the basis of serpentiform locomotion. Contrary to the idea expressed in the conventional representations of snakes, the body is not undulated vertically but laterally, and locomotion is effected by the passage of a series of "waves" from before backwards, each wave in its progress pressing against the surrounding medium and forcing the animal forwards. Such a system is efficacious only when the surrounding medium is sufficiently dense to offer an appreciable resistance to the passage of the waves and the majority of terrestrial snakes possess an additional mechanism. The scales of the lower surface are enlarged to form transverse, overlapping plates, whose free edge is directed backwards, and to each of these plates is attached a pair of movable ribs. When the ribs are moved forwards they carry the scute with them, and as this is smooth and has its leading edge protected by the one in front of it, it slips easily over any irregularities of the surface. But, when the scute is moved backwards its free, hinder edge catches on the slightest projection and so enables the snake to push itself forward. As there may be as many as 300 of these ventral shields, each of which can utilise any slight irregularity, progress is possible over almost any surface which is not absolutely smooth.



THE FER-DE-LANCE OF THE WEST INDIES AND SOUTH AMERICA

Probably also correlated with the ancestral habitat is the development of a hard transparent covering over the eye to protect the delicate cornea; in many lizards a transparent covering is developed from the lower eyelid, but in snakes the analogous covering is probably the modified nictitating membrane. In most snakes the outer horny covering of the scales is shed in one piece; sloughing commences at the lips and by vigorous rubbing movements the slough is turned back on itself and the animal works its way out, the old skin being turned inside out in the process. Though the sense of sight is well-developed, hearing must be of a different nature from that of most vertebrates, as there is no external ear or ear-drum; the *columella auris*, which normally transmits vibrations from the ear-drum to the inner ear, in snakes rests with its outer end on the quadrate, the bone which supports the lower jaw; possibly the ear is sensitive, not to air-borne vibrations, but to vibrations transmitted through the substratum on which the animal rests. The sense of smell is well-developed but a snake's most important sensory organ is its tongue; exactly what sense is centred here is not known, but the constant play of this organ makes it evident that the sensations which it registers are of paramount importance in determining the animal's reactions to external conditions.

Practically all snakes are carnivorous and the prey, which under natural conditions must be captured alive, is swallowed whole, the conical re-curved teeth and the divided lower jaw being adaptations to this method of feeding. The prey may be killed by poison or constriction or swallowed alive; it is worked round until the head is in the snake's mouth and then commences the laborious swallowing process. The bones supporting the lower jaw are movable on the skull so that the gape of the mouth is tremendous and this, assisted by the stretching of the elastic ligament between the halves of the lower jaw, permits the swallowing of masses of considerably greater diameter than the snake itself; the teeth of one side of the mouth are hooked into the victim and then, with this as a fulcrum, the other side is pushed forwards a short distance, the teeth engaged and the same action repeated with the opposite side. The hooked shape of the teeth permits of their being pushed forward but not easily drawn back, and in this way the snake literally draws itself over its food. Teeth are frequently broken off by the victim's struggles, but by the side of each functional tooth is a series of new teeth, in different stages of development, lying within a special fold of the lining of the mouth, the *vagina dentis;* as soon as a tooth is lost one of the successional series moves into its place and becomes fused to the jaw-bone. Teeth are also the means by which the venom of poisonous species is injected; these "poison fangs" are always situated in the upper jaw either at the front or the hind end and the channel for the venom is either a simple groove or a groove whose edges have met and so produced a tube with openings at the base and the tip of the fang. The venom itself is the product of a modified salivary gland and is a clear straw-coloured liquid containing certain poisonous proteins, the proportions in which each is present varying according to the type of snake. The two principal constituents are a "haemolytic" agent which breaks up the blood corpuscles and attacks the lining of the blood vessels and a "neurotoxic" agent which attacks the nerve centres, causing paralysis, and having a special affinity for the nerves supplying the respiratory apparatus; the predominance of one or other of these two bodies determines the nature of the symptoms of snake-bite. If neurotoxic agents predominate, paralysis, general prostration and difficulty in breathing are the most dangerous symptoms, but if the patient survives this stage, recovery is rapid and there are few severe local symptoms at the site of the bite; when, on the other hand, "haemolysins" are the principal constituents of the venom there is no paralysis, though there are severe constitutional symptoms and prostration, but even if this is not fatal, local symptoms follow with local extravasation of blood and much swelling of the bitten parts, which may suppurate and become gangrenous. The venom is destroyed by oxidising agents, such as potassium permanganate, silver nitrate and hypochlorites, and this characteristic is the basis on which first-aid treatment should be given. A ligature should be applied above the fang punctures and then a free incision made into the wounds which should, if possible, be washed out with a solution of bleaching powder or potassium permanganate. The ligature must not be kept on for more than half an hour at a time, being released for a few seconds occasionally to allow the circulation to return before it is re-applied. Administration of large quantities of stimulants is useless, but small repeated doses may be given if the patient is on the verge of collapse. Despite a large number of so-called "cures" there is only one reliable treatment for snake-bite, and that is by the use of "anti-venines" which are now manufactured in most countries where snake-bite is at all common. They are prepared by immunising horses against a particular venom by increasing, regulated doses; the blood serum of the horses is then sterilised and made up into doses ready for inoculation. It has not yet been found possible to prepare a serum which is really efficacious against the venoms of more than one or two snakes, so that, to ensure treatment with the correct anti-venine, an attempt should be made to identify the one responsible for the accident. Above all, the earlier an anti-venine is administered the better.

No snakes have a larynx or vocal chords and, in consequence, none have a true voice; they are all, however, capable of hissing and some of the larger, heavy-bodied species, with a large lung capacity, can do so loudly enough to be heard at some little distance; a few forms have a special piece of cartilage in front of the epiglottis and, when a blast of air is emitted, the vibration of this cartilage produces a sound which has been compared with that of a gently struck tuning fork. Rattlesnakes (*q.v.*) have a special sound-producing apparatus and some vipers can make a swishing noise by the movement of the scales one over the other.

The majority of snakes lay eggs; these are elongate with a parchment-like shell, and are usually deposited in a situation exposed to moist heat. In some groups, however, they are retained inside the body of the mother until the young are fully developed.

The various families, based largely on characters of the skull, may best be considered separately.

1. *Typhlopidae.*—Small, harmless, burrowing, worm-like snakes, with the eyes hidden beneath the scales of the head, with a very short, blunt tail, with small, shiny over-lapping scales, no enlarged scutes across the belly and with teeth only in the upper

jaw; inhabitants of almost all tropical countries. These snakes form burrows in loose soil, and to assist in this operation many have a short spine at the tip of the tail which is dug into the ground to obtain a purchase whilst the rounded head is thrust forward, or retracted, by a looping movement of the body; insect pupae and larvae, ants and earth-worms, seem to form the staple diet. The commonest colouring is brownish or flesh colour, but a few, for instance the common *T. punctatus* of tropical Africa, are irregularly marked with black and yellow.

2. *Leptotyphlopidae* (*Glauconiidae*).—Another family of blind, burrowing snakes very similar to the *Typhlopidae* from which they differ in having teeth in the lower, but not in the upper jaw; they are found in Africa, south-western Asia and America. The usual colours are browns or blacks but in *Leptotyphlops albifrons,* the common species of tropical America and the lesser Antilles, the forehead and tip of the tail are white. As the head and tail are also similar in shape, the colouring may be of the "directive mark" type designed, apparently, to enhance the resemblance of the two for the confusion of any would-be attacker.

3. *Ilysidae.*—Harmless burrowing snakes, without any distinct neck but with the cylindrical body tapering slightly at either end, with a pair of claw-like vestiges of hind limbs visible on either side of the vent and with slightly enlarged scales on the belly; teeth are present in both jaws. The few members of this family are larger than most burrowing snakes, attaining a size of 2½ to 3 ft.; they seldom appear above ground but take readily to water, and their food seems to consist principally of other snakes and eels, all, so far as is known, are ovoviviparous. *Ilysia scytale,* of tropical South America, coloured a beautiful coral-red with more or less complete black rings, superficially resembles some true coral snakes (*Micrurus*); as the latter are all venomous this is often regarded as an instance of mimicry. *Cylindrophis rufus* of Burma, the Malayan Region and the East Indies also exhibits what appears to be mimicry, but of a different kind; the upper surfaces are brown or black, with, as a rule, light cross-bars, the belly is white with transverse black bands, and the tail bright red beneath. When the snake is brought above ground the tail is bent sharply upwards exhibiting the brilliant lower surface and if the animal is touched the tail snaps round in the manner of a striking head. Precisely the same tail colour and actions occur also in another burrowing snake of the same regions, *Doliophis intestinalis,* but this animal is not only venomous but possesses the largest poison glands of any Elapine snake.

4. *Uropeltidae.*—Harmless burrowing snakes similar to those of the preceding family, but without any vestiges of hind limbs and with the tail ending in an enlarged scale which is either rugose or produced into two short points. The "earth-snakes" of Ceylon and the hills of southern India are all burrowers in loose earth in damp, forested regions and feed almost exclusively upon earth-worms; those whose breeding habits are known are all ovoviviparous.

5. *Xenopeltidae.*—This family contains but a single species, *Xenopeltis unicolor* of south-eastern Asia, a handsome snake with highly iridescent black or dark brown scales, each of which has a lighter edge; the head is small, not sharply marked off from the rest of the body and covered with enlarged shields; there are no traces of hind limbs, teeth are present in both jaws, the tail is short and the belly is covered with transversely enlarged scutes; total length about 3 feet.

6. *Boidae.*—Non-poisonous, often large, snakes with claw-like rudiments of hind-limbs visible on either side of the vent, enlarged scutes on the belly and teeth in both jaws. This family, which is represented throughout the tropical and sub-tropical regions of the world, is sub-divided into two groups, the Pythons, which are most numerous in the Old World, and the true Boas, whose headquarters are in tropical America with only a few scattered forms in other parts of the globe. These two subdivisions are not recognisable by any external characters, the *Pythoninae* only differing from the *Boinae* by the presence of an extra bone (the supraorbital) in the skull.

(a) *Pythoninae: see* PYTHON.

(b) *Boinae.*—The majority of Boas are arboreal or semi-arboreal, and correlated with this habit the tail is usually more or less prehensile; all kill their prey (chiefly small mammals and birds) by constriction, and all those whose breeding habits are known are ovoviviparous, in contrast with the Pythons which usually lay eggs. Though the name "Boa Constrictor" is frequently used to designate any large snake it is only strictly applicable to a single South American species, *Constrictor constrictor,* which is not particularly large, attaining a total length of only about 11 feet. The genus *Boa* contains a number of species in tropical America, including the West Indies, and two in Madagascar; *Corallus,* another very similar genus, has a similar distribution. The largest species is the Anaconda (*Eunectes murinus*), which inhabits the forests of the Amazon basin and is said to reach a length of 30 ft., though actually, specimens of even 25 ft. seem to be very rare. The animal is largely aquatic and is usually found along the banks of rivers or in swampy regions; it is dark green in colour with numerous, sharply defined, round, black spots and is highly iridescent. In the Old World, *Enygrus* occurs in the islands around New Guinea and on those of Polynesia as far east as Fiji; all the species have prehensile tails. *Eryx,* with about seven species, is an assemblage of small, sand-loving forms in north Africa, south-east Europe and south-west Asia; none of them greatly exceed 3 ft. in length and all have small heads, merging imperceptibly into their bodies, and short, scarcely prehensile tails.

7. *Colubridae.*—This family comprises the great majority of snakes and its members show great diversity of habits and adaptations. In the restricted sense in which the name is here used the family may be defined as follows:—typical snakes, without any rudiments of limbs, with the head usually covered by enlarged scales, with enlarged ventral scutes, with teeth in both jaws and poison fangs, if present, situated on the hinder end of the upper jaw and preceded by smaller, solid teeth; distributed over all the temperate and tropical regions. Every kind of terrain is tenanted, from dense tropical forests to deserts and high mountains, and so uniform are the modifications connected with their different habits that, from its appearance, alone it is possible to draw a fairly safe conclusion as to a snake's mode of life. Burrowing forms are invariably small with relatively short tails, with small heads merging imperceptibly into the body and with greatly reduced eyes; desert dwellers are usually rough-scaled, with pallid or sombre colouring; terrestrial species have cylindrical bodies, a distinct neck and moderately long tails; arboreal snakes are greatly elongate with whip-like tails, long, pointed snouts, very large eyes and a more or less compressed body; thoroughly aquatic forms have the nostrils on the top of the snout and fitted with valves which can be closed while the animal is under water and, as a rule, the enlarged ventral scutes, so necessary for locomotion on land, are reduced. Two groups of Colubrids can be recognised thus:—

Aglypha, without any grooved teeth.

Opisthoglypha, with one or two enlarged, grooved, poison fangs at the rear of the upper jaw.

These two groups, the one harmless, the other venomous, but, on account of the position of the poison fangs, rarely dangerous to man, almost grade into one another, a few species being known in which the posterior teeth are only slightly enlarged and sometimes grooved and sometimes not; they also show a curious parallelism. The *Aglypha* are again sub-divisible into four "sub-families."

(a) *Dipsadinae.*—Arboreal forms with the anterior teeth in both jaws enlarged and without a groove beneath the chin. This groove, present in almost all other colubrids, is part of the mechanism which allows of the two halves of the lower jaw being pushed apart in swallowing bulky objects and its absence in the Dipsads is connected with the feeding habits of the group; they appear to feed exclusively on slugs. *Amblycephalus* and *Haplopeltura* occur in south-east Asia and the Malay Archipelago and *Dipsas* and its allies are confined to Central and tropical South America.

(b) *Acrochordinae.*—Aquatic snakes with valvular nostrils on the upper surface of the snout; they are heavy-bodied animals

frequenting fresh-waters and estuaries in south-east Asia and Central America, and feeding on fish. In a few the enlarged ventral scales are scarcely distinguishable and the common Indo-Malayan *Chersydrus* has the body laterally compressed and equipped with a fold along the lower surface; this fold, simulating a median fin, the compressed body and the absence of ventral shields bespeak an existence spent wholly in water. The less specialised forms with cylindrical bodies and retaining the ventral scutes are still capable of rapid movement on land.

(c) *Dasypeltinae* (*Rhaciodontinae*).—Terrestrial snakes with only a few small teeth but with downwardly directed projections, which penetrate the oesophagus, on some of the vertebrae of the neck; a few species only, in tropical and South Africa. These snakes are highly modified egg-eaters; the mouth is enormously distensible and the egg is swallowed whole; when, however, it comes in contact with the vertebral processes in the throat its progress is arrested, and by compression of the muscles of the neck, and backward and forward sawing motions, the shell is cut through and collapses; the contents of the egg run down into the stomach and the shell is rejected.

(d) *Colubrinae*.—Typical snakes, with well-developed teeth in both jaws, with a dental groove and with, as a rule, lateral nostrils. This sub-family is cosmopolitan and its members may be more or less aquatic, arboreal, terrestrial or cryptozoic; as a rule they are oviparous, but some produce fully developed young. Perhaps the most thoroughly aquatic species is *Glypholycus bicolor* which inhabits Lake Tanganyika and in the general shape and the position of the nostrils superficially resembles the *Acrochordinae*. The common English Grass snake (*Natrix natrix*) is a member of a widely distributed genus whose members, though not strictly aquatic, are water loving and whose food consists principally of frogs and fish; *N. natrix*, widely distributed through northern Europe, is very variable in colour, but is usually a greyish-green with some black markings on the back, traces of an incomplete yellow or orange collar on the neck and chequered black and white beneath; it frequents damp and marshy localities and feeds principally on frogs. Its European relative *N. viperinus*, very common in Spain and Portugal, is more aquatic still and feeds almost exclusively on fish, and the Indian Keel Backs (*N. piscator*) and the North American Moccasins (*N. fasciatus*) have similar habits. Allied to *Natrix* are the N. American Garter snakes (*Thamnophis*), a group of likewise semi-aquatic species. The strictly terrestrial genera, very numerous throughout most of the world except the Australian region, feed chiefly on small mammals, birds, toads and lizards. The Rat snakes or Racers of Europe and N. America (*Coluber*) the Chicken snakes (*Elaphe*) and the Indian Rat snakes (*Ptyas*) are all externally of very similar build and either kill their prey by constriction or eat it alive. *Coronella*, another similar genus, is represented in Britain by the Smooth snake (*C. austriaca*), a species frequently confused with the viper but readily distinguished by its smooth scales and the enlarged plates on the top of the head; the species of this genus feed largely upon lizards, and the distribution of the Smooth snake in England corresponds exactly with that of the Sand lizard. Other terrestrial genera with specialised feeding habits are the King snakes (*Lampropeltis*) of N. America, and the African *Lycophidion*. The species of the first-mentioned genus live almost exclusively on other snakes, poisonous or harmless, the victim being killed by constriction; some "mimic" Coral snakes in their colour pattern which consists of broad reddish bands edged with black and separated by narrower yellowish or buff interspaces. *Lycophidion* is characterised by enlarged teeth on the front of both jaws, the "canine" teeth being also directed outwards, and this is probably an adaptation to enable them to hold the smooth, hard-scaled skinks which form their principal diet. The American Hog-nosed snakes (*Heterodon*) are remarkable for their superficial similarity to vipers, due to the broad, flat head and stout body; if annoyed they puff themselves up and hiss in true viperine manner, but if this fails to intimidate the enemy they roll over on their backs and "sham dead." Tree-snakes are greatly elongate, slender creatures and are represented by such genera as *Dendrophis* of south-east Asia and Australia and *Leptophis* of South America; they feed principally on lizards and young birds.

Opisthoglypha.—The back-fanged snakes are divisible into three sub-families which exactly parallel the last three divisions of the preceding group.

(a) *Homalopsinae Aquatic* snakes with valvular nostrils situated on the top of the snout, and often with the ventral scales much reduced. They are confined to the fresh waters and estuaries of south-east Asia, Papua and North Australia and are all ovoviviparous.

(b) *Elachistodontinae*.—The single snake of this sub-family, known only from a few specimens from Bengal, is the exact Opisthoglyphous analogue of the Aglyphous *Dasypeltis;* it is an egg-eater, with reduced dentition and with vertebral processes penetrating the oesophagus.

(c) *Boiginae* (*Dipsadomorphinae*).—This sub-family parallels the Colubrinae; its members are cosmopolitan and adapted to the same types of habitats, though in this group arboreal forms predominate. Among these may be mentioned a few which are remarkable for their habits or appearance; the slender, bodily form and elongate head is exaggerated in some, such as *Dryophis mycterizans* of the Indian Region or *Langaha* of Madagascar, by the production of the tip of the snout into a pointed or leaf-like dermal appendage. Many of these tree-snakes are brilliantly green to match the foliage, others brown to harmonise with the branches, but some show brilliant colour patterns which, though conspicuous when removed from their natural surroundings, are almost invisible in the dappled light and shade of the bushes which the animals frequent. *Chrysopelea ornata* of India and Malaya is often black with yellow dots on the centre of each scale and a series of red-centred yellow, tetra-petalous flowers along the back. This species is also famous as the Flying snake, a name it has earned by its ability to "glide" to a limited extent; to accomplish this feat the body is held straight and rigid, the ribs pushed outwards to their full extent and the belly drawn in so that a considerable concave surface is produced which checks the fall of the animal and enables it, in an emergency, to descend with safety from a considerable height. Some members of the group, for instance the Boomslang (*Dispholidus typus*) of South Africa, have the peculiar habit of expanding the neck to form a vertical "hood" when annoyed. Unlike the horizontal hood of the cobras, which is produced by an outward pressure of the ribs, this vertical "hood" is brought about by inflation of the wind-pipe. In snakes the cartilaginous rings of the trachea are incomplete along the side nearest the backbone, and a strip of tissue between their free ends is very distensible, so that, when air from the lungs is forced into the wind-pipe, this elastic tissue stretches and the neck is inflated.

Terrestrial genera are represented in Europe by *Coelopeltis*, one of the largest snakes of the continent, in the Mediterranean countries. *Erythrolamprus aesculapii* of Tropical America is a very variable species whose many colour varieties mimic Coral snakes; sometimes the groove, on the fangs may be absent. Africa has many terrestrial forms, of which the commonest are the Sand snakes (*Psammophis*), and also several burrowing genera, e.g., *Miodon* of West Africa and *Aparallactus* from the east and south. Some burrowing forms, notably *Apostolepis* in South America, exhibit "directive mark" coloration; the body is yellow, sometimes with longitudinal black stripes, and the head and stumpy tail are black with a few lighter dots, so that the similarity of the two ends is remarkable.

Only a few Opisthoglyphs can be considered as dangerous to man; the situation of the fangs renders it difficult for any but the very large species to bring them into play except on the smallest objects. Should, however, a wound be inflicted by one of the larger species, such as the Boomslang, the consequences are apt to be dangerous; the venom is largely haemolytic in its action and resembles that of the vipers rather than that of the cobras and their allies.

8. *Micruridae* (*Elapidae*).—Sometimes regarded as Colubrids, these snakes are "proteroglyphous," *i.e.*, have fixed poison fangs in the front of the upper jaw and they always have well-developed ventral shields. Apart from the Cobras (*q.v.*), this family con-

SNAKES

There are more than 2,000 kinds of snakes. Some 600 are more or less venomous, but only a comparatively small number are fatally poisonous to man. The illustration shows the European viper, the only poisonous serpent found in Great Britain, together with five highly venomous snakes, marked *Ven.* and three large but harmless snakes found in North America

Top, left: Coral Snake (*Micrurus fulvius*), *Ven.* Top, right: Water Moccasin (*Agkistrodon piscivorus*), *Ven.* Top, centre: Head of Diamond-back Rattlesnake (*Crotalus adamanteus*), *Ven.* Second row: left, Texas Rattlesnake (*Crotalus atrox*), *Ven.*; right, King Snake (*Lampropeltis getulus*). Third row: left, Copperhead (*Agkistrodon mokasen*), *Ven.*; right, Water Snake (*Natrix sipedon*). Bottom; left, European Viper (*Vipera berus*); right, Bull Snake (*Pituophis sayi*)

tains other genera in the same regions, the true Coral snakes of Central and South America and a number of forms in Australia. Some of the best known of the latter are the Black snake (*Pseudechis*), which reaches a length of 6 ft. and can erect a small cobra-like hood, the Tiger snake (*Notechis*) and the Death Adder (*Acanthophis*); the latter has acquired its appellation of "Adder," which usually means viper, on account of its broad, flat head, which lacks the large shields of the other Micruridae, and its thick-set body. In the Indian region, the larger species are the Kraits (*Bungarus*) whose bite, though not so deadly as that of the Cobras, is responsible for a heavy mortality annually. The dreaded Mamba (*Dendraspis angusticeps*) of tropical and South Africa also belongs to this family, and is one of the few arboreal species in it. Two varieties are commonly recognised, a black, which is really a dark olive, and a green, and as no very small black ones have ever been recorded and the green variety is usually the smaller of the two, it seems probable that the "varieties" are growth stages of the one species; the green phase is almost entirely arboreal but the black is frequently terrestrial. The Coral snakes (*Micrurus* or *Elaps*) are the only representatives of this family in America; they are distributed all over the hotter parts of that continent and are largely burrowing and cryptozoic forms. *Doliophis*, another genus of burrowing animals from the Malayan region, is remarkable for the enormous development of the poison glands, which extend over the anterior third of the body, and for its habit, when annoyed, of raising the tail to show the red colour of its lower surface.

The larger snakes of this family are all highly dangerous to man; the venom is chiefly neurotoxic in its action, as compared with the more haemolytic venom of the back-fanged Colubrids and Vipers.

9. *Hydrophiidae.*—Sea-snakes. Elapids adapted to aquatic life, with valvular nostrils on the top of the snout, vertically flattened tails and the ventral shields greatly reduced or entirely absent; all produce their young fully developed. The snakes of this family, some 55 all told, are divided into two sub-families, the one (*Laticaudinae*) Australian in origin, the other (*Hydrophiidae*) Indo-Malayan; they are found throughout the tropical waters of the Indian and Pacific Oceans, but not in the Atlantic, and, though many are admirably adapted for aquatic life, and indeed are quite helpless on land, they chiefly frequent inshore waters and are most numerous around the coasts of the Indian region and along the chain of islands to north Australia; all are venomous, though the majority are very docile. The majority do not exceed four feet in length but a few reach a length of eight feet or more and many are of great girth, the greatest diameter being in the posterior half of the body, which gradually tapers towards the head; colours, as a rule, are indistinct transverse bands of darker and lighter but the most widely distributed species *Pelamis platurus*, which ranges from the east coast of Africa to the west coast of America, is uniformly black above and yellowish or brown beneath, the two colours being sharply defined in a straight line along the sides but forming vertical bars or spots on the tail.

10. *Viperidae.*—Vipers and rattlesnakes are characterized by the possession of poison fangs situated on the front of an upper jaw which is movable so that the teeth, when not in use, can be folded down parallel with the roof of the mouth; cosmopolitan except the Australian region and Madagascar. As a rule the members of this family are stoutly built, with flattened heads which lack the large plates so characteristic of the majority of the other poisonous snakes. For further details *see* VIPER. (H. W. P.)

SNAPDRAGON or **ANTIRRHINUM,** a plant of the family Scrophulariaceae (*q.v.*), native to central and south Europe, occurring as an alien on old walls in Great Britain and sparingly naturalized in eastern North America. It is an old-fashioned garden perennial of easy cultivation. *Antirrhinum majus*, sown in heat, and forwarded until the general time for planting out, becomes a summer annual, and may be so treated; but under a slower and more hardy régime it may be sown in boxes in August, and pricked off into other boxes and wintered in a frame. So treated, and planted out in well-prepared beds of good garden soil, it is very showy and effective. The genus contains some 40 species, all herbs native to the northern hemisphere, but especially numerous in western North America, 13 species occurring in California, all herbaceous, except *A. speciosum*, an evergreen shrub, 3 to 8 ft. high, with scarlet flowers, found on Santa Catalina and San Clemente islands.

SNEEK, a town in the province of Friesland, Holland, to the west of Sneek lake, 14 m. by rail S.S.W. of Leeuwarden, with which it is also connected by canal. Pop. (1927), 14,527. One of the former city gates (1615) remains, and in one of the churches is the tomb of the naval hero of the 16th century, Lange, or Groote Pier (Long or Great Peter). Sneek is one of the great butter and cheese markets of the province. Its horse-fair is widely attended.

SNEEZING, a violent expiration of air from the nose and mouth; it is an involuntary reflex respiratory act, caused by irritation of the nerve-endings of the mucous membrane of the nose or by stimulation of the optic nerve by a bright light. The irritation may be due to the swelling of the nasal mucous membrane, sneezing often accompanying nasal catarrh, or to foreign bodies in the nose, as by inhalation of snuff. A venerable and widespread belief survives in the custom of saying "God bless you" when a person sneezes. The Hindus say "live," to which the answer "with you" is given (E. B. Tylor, *Primitive Culture*, i. 101). A sneeze was considered a sign or omen from the gods by the Greeks and Romans.

SNELL, HANNAH (1723–1792), the "female soldier," was born at Worcester on April 23, 1723, being the daughter of a hosier. In order to seek her husband, who had ill-treated and abandoned her, in 1745, she donned man's attire and enlisted as a soldier in Guise's regiment of foot, but soon deserted; she then shipped on board the sloop "Swallow" and took part in the siege of Pondicherry and was wounded. She served before the mast on the "Tartar" and the "Eltham," but when paid off she resumed woman's costume. Her adventures were published as *The Female Soldier, or the Surprising Adventures of Hannah Snell* (1750). She died insane in Bethlehem Hospital on Feb. 8, 1792.

SNELL, WILLEBRORD (1591–1626), commonly known as SNELLIUS, Dutch astronomer and mathematician, was born at Leyden in 1591. In 1613 he succeeded his father Rudolph Snell (1546–1613) as professor of mathematics in the university of Leyden. In his *Eratosthenes Batavus* (1617), he describes his method of measuring the earth, and gives as the result of his operations between Alkmaar and Bergen-op-Zoom a degree of the meridian equal to 55,100 toises (=117,449 yd.). Snell is known as the discoverer of the law of refraction (1621). (*See* LIGHT.) He died at Leyden on Oct. 30, 1626.

SNIPE, one of the commonest wading birds, in high repute both with the sportsman and epicure. The common snipe (*Capella gallinago*) breeds in marshes all over Europe and northern Asia, moving south in hard weather. It feeds upon worms, etc. which it obtains by probing the ground with its long bill. In this connection the tip of the latter is flexible and very sensitive. When disturbed, the snipe rises suddenly with a curious twisting flight and a sharp cry, soon settling down, however, to swift straight flying. During the breeding season, the male circles at a considerable height, uttering a sustained cry and plunging down a few feet from time to time, thus producing a bleating sound by the vibration of the outer tail feathers. Snipe have also been known to swoop down from a great height and then skim along horizontally for some distance back downwards. The nest is on the ground, and is a deep hollow lined with dry grass. The striped plumage blends beautifully with the surrounding rushes and grasses. The four eggs are dark olive in colour, while the young are clad in protectively coloured down. Both male and female may sit on the nest together. In North America, Wilson's Snipe, *C. delicata*, differs only from the Old World form in possessing 16 instead of 14 rectrices in the tail.

The Double Snipe (*C. media*) is larger, and much less common. It inhabits northern Europe. The Jack or Half-Snipe (*Lymnocryptes minimus*) is the smallest and most beautiful of the group. It breeds in northern Scandinavia and Russia.

The painted snipes (*Rhynchaea*) of the southern hemisphere

are interesting in that the female is larger and more brightly coloured than the male, who undertakes the incubation.

SNOILSKY, CARL JOHAN GUSTAF, COUNT (1841–1903), Swedish poet, was born at Stockholm on Sept. 8, 1841. He was trained for diplomacy, which he quitted for work at the Swedish Foreign Office. In 1862 he published *Orchideer*. During 1864–65 he was in Madrid and Paris on diplomatic missions. In 1869 he first collected his *Dikter* under his own name. His *Sonneter* in 1871 increased his reputation. Then, for some years, Snoilsky abandoned poetry, and devoted himself to the work of the Foreign Office and to the study of numismatics. In 1876, however, he published a translation of the ballads of Goethe. Snoilsky had in 1876 been appointed keeper of the records, and a member of the Swedish Academy. But in 1879 he resigned, and left for Florence with the Baroness Ruuth-Piper, whom he married in 1880. His later volumes are four other volumes of *Poems* (1881–83–87–97); *Savonarola*, a poem, in 1883, and *Hvita frun* ("The White Lady") in 1885. In 1886 he collected his poems dealing with national subjects as *Svenska bilder* (2nd ed., 1895), In 1891 he returned to Stockholm, and was appointed librarian of the Royal Library. He died at Stockholm on May 19, 1903.

His *Samlade dikter* were collected (Stockholm, 5 vols.) in 1903–1904. *See* C. Warburg, *Carl Snoilsky, Hans lefnad och skaldscap* (1905).

SNORRI, STURLASON (1179–1241), the celebrated Icelandic historian, the youngest son of a chief in the Vestfirðir (western fiords), was brought up by a powerful chief, Jon Loptsson, in Odda, who seems first to have awakened in him an interest for history and poetry. His career begins with his marriage, which made him a wealthy man; in 1206 he settled at Reykjaholt, where he constructed magnificent buildings and a bath of hewn stones, preserved to the present day, to which water was conducted from a neighbouring hot spring. He early made himself known as a poet, especially by glorifying the exploits of the contemporary Norse kings and earls; at the same time he was a learned lawyer, and from 1215 became the *lögsögumaðr*, or president of the legislative assembly and supreme court of Iceland. The prominent features of his character seem to have been cunning, ambition and avarice, combined with want of courage and aversion from effort. By royal invitation he went in 1218 to Norway, where he remained a long time with the young king Haakon and his tutor Earl Skuli. When, owing to disputes between Icelandic and Norwegian merchants, Skuli thought of a military expedition to Iceland, Snorri promised to make the inhabitants submit to Haakon of their own free will. Snorri himself became the *lendrmaðr*, vassal or baron, of the king of Norway, and held his lands as a fief under him. On his return home Snorri sent his son to the king as a hostage, and made peace between Norway and Iceland, but his power and influence were used more for his own enrichment and aggrandizement (he was *lögsögumaðr* again from 1222 to 1232) than for the advantage of the king. Haakon, therefore, stirred up strife between Snorri's kinsman Sturla and Snorri, who had to fly from Reykjaholt in 1236; and in 1237 he left the country and went back to Norway. Here he joined the party of Skuli, who was meditating a revolt. Learning that his cousin Sturla in Iceland had fallen in battle against Gissur, Snorri's son-in-law, Snorri, although expressly forbidden by his liege lord, returned to Iceland in 1239 and once more took possession of his property. Meanwhile, Haakon, who had vanquished Skuli in 1240, sent orders to Gissur to punish Snorri for his disobedience either by capturing him and sending him back to Norway or by putting him to death. Gissur took the latter course, attacked Snorri at his residence, Reykjaholt, and slew him on Sept. 22, 1241.

Snorri is the author of the great prose *Edda* (*see* EDDA), and of the *Heimskringla or Sagas of the Norwegian Kings*, a connected series of biographies of the kings of Norway down to Sverri in 1177. Snorri's sources were partly succinct histories of the realm, such as the chronological sketch of Ari; partly more voluminous early collections of traditions, as the *Noregs Konungatal* (*Fagrskinna*) and the Jarlasaga, partly legendary biographies of the two Olafs; and, in addition to these, studies and collections which he himself made during his journeys in Norway. His critical principles are explained in the preface, where he dwells on the necessity of starting as much as possible from trustworthy contemporary sources, or at least from those nearest to antiquity—the touch-stone by which verbal traditions can be tested being contemporary poems. He inclines to rationalism, rejecting the marvellous and recasting legends containing it in a more historical spirit; but he makes an exception in the accounts of the introduction of Christianity into Norway and of the national saint, St. Olaf. Besides his principal work, he elaborated in a separate form its better and larger part, the *History of St. Olaf* (the great *Olaf's Saga*). In the preface to this he gives a brief extract of the earlier history, and, as an appendix, a short account of St. Olaf's miracles after his death. (*See* further ICELAND: *Literature,* and EDDA.)

SNOUCK HURGRONJE CHRISTIAAN: *See* HURGRONJE, CHRISTIAAN SNOUCK.

SNOW, FRANCIS HUNTINGTON (1840–1908), an American scientist and educator, was born at Fitchburg, Mass., on June 29, 1840. He graduated at Williams college in 1862 (A.M., 1865; Ph.D., 1881) and at Andover Theological seminary in 1866. He was professor of mathematics in 1866–70, professor of natural science in 1870–89, chancellor in 1890–1901, and professor of entomology and meteorology in 1901–08, at the University of Kansas. On his numerous scientific expeditions to the South-west, he made the university's collections of insects, housed in the Snow hall of natural history, one of the largest in the United States. He died at Delafield, Wis., Sept. 21, 1908.

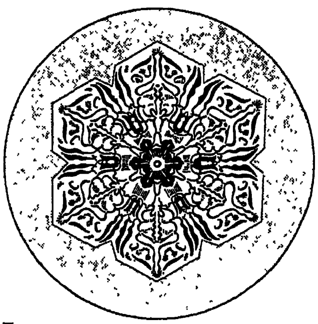

FIG. 1.—SOLID HEXAGONAL FORM OF SNOWFLAKE, HIGH CLOUD TYPE

SNOW, the water vapour in the air crystallized into geometrical forms. Snow forms usually within, below or between cloud strata, and at various heights within the atmosphere, according to the latitude and the temperature prevailing within the clouds. Snow forms in great quantities within lofty clouds in all latitudes. In the tropics, however, it melts into raindrops as it falls, except when it alights upon high mountains. Although most common to the polar region, it doubtless forms in even greater quantity within the north temperate regions, because the air contains much more moisture at lower latitudes than at the poles.

Over the polar regions and upon the tops of lofty mountains perpetual snow covers most of the land to a depth in most cases of many feet. On mountain or plateau regions therein, and on high mountains elsewhere, it accumulates to so great an extent and depth that the pressure of the upper masses converts it into ice, thus forming glaciers, which in the polar regions cover thousands of square miles. In the higher latitudes of the temperate regions it often accumulates to the depth of from one to four or more feet during the winter. It rarely falls in quantity or remains long on the ground on low lands below 30° of latitude. Owing to many causes, both topographical and meteorological, the amount of snowfall varies markedly upon mountain tops and other locations even when situated upon the same parallel degree of latitude. The limit of perpetual snow upon mountains approximates 1,000ft. at 70°; 5,000ft. at 60°; 7,000ft. at 50°; 10,000ft. at 40°; 13,000ft. at 30°; 15,000ft. at 20° and 17,000ft. at the equator.

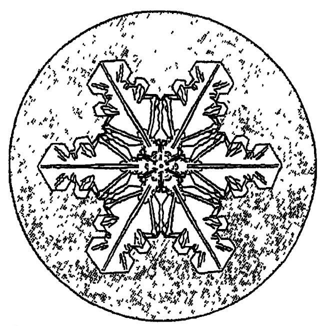

FIG. 2.—TABULAR FORM OF SNOWFLAKE, HIGH CLOUD TYPE

The crystalline varieties of snow are for the most part transparent, and have brilliant facets that reflect light and give them a white appearance in the mass. They vary in size from $\frac{1}{100}$ to

½ of an inch in diameter, and fall to earth either singly or bunched together into flakes. Flake formation occurs most commonly during the mild, moist snowfalls when the temperature at the ground is 32° or above. Their size depends both upon the temperature wherein they form and the depth of the cloud strata through which they fall or float. Intensely cold clouds are always relatively dry, hence tend to produce the smaller, slow growing and solid type of crystal. Conversely, warmer clouds (usually the lower clouds) contain much more moisture and tend to produce the larger, fast growing, branchy type of crystals. Water being a product of the joining of the two gases, hydrogen two parts, oxygen one part, its nuclear atoms have such an arrangement as to favour the formation of triangular or hexagonal forms and to divide into three or six.

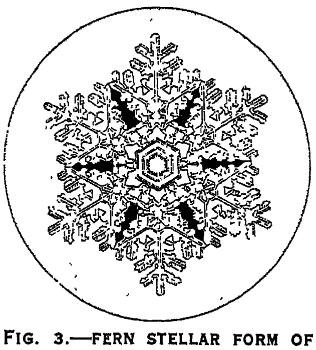

FIG. 3.—FERN STELLAR FORM OF SNOWFLAKE, LOW CLOUD TYPE

The great mass of the crystals of snow have forms whereby they can be roughly grouped into two main classes, columnar and tabular forms. Comprised in the columnar forms are hexagonal columns, both hemihedral and holohedral, and the long, slender, needle-like columns. Grouped in the tabular class are all those, whether solid or branching, that form on a thin, tabular plane. Among the rarer forms are the three or four vaned crystals, twin crystals, four-sided plates and compound forms. The latter consist of a hexagonal column having solid or branching tabular forms attached at one or both ends, and rarely also at the middle of the column. There are in addition many irregular snow forms, among them icy spicules growing outward at many angles from a granular nucleus, frost-like forms and forms due to twinning, etc. During extreme cold or snowfall from very lofty, cold clouds, tiny columns and solid hexagonal or triangular plates usually predominate.

The order of the types in furnishing the bulk of the snowfall is as follows: branching tabular forms, granular forms, plates with branching exteriors, plate forms, columns, needle forms, compound forms. The columnar and needle-like forms are, each in their respective classes, much alike, though they vary in size, length, thickness, etc. Compound crystals show much greater variation one from another, owing to the differences in the size, aspect, interior details, etc., of the end plates. Often the bar connecting the end plates is exceedingly short, resembling a tiny thick hexagonal plate. As a result, the end plates grow outward very close together. When one of the end plates is smaller than the opposite one, it converts the crystals into the semblance of tiny parachutes, and they fall with the smaller plate downward.

By far the most important, varied and beautiful snow crystals are those that comprise the tabular class. Crystals of this class assume delicate, starry, branching forms, solid plate forms and those exhibiting all gradations between the solid and wholly open forms. Rarely is it that any two of them are just alike. The beauty of outline and richness of interior of such crystals are so great as to have attracted the attention and admiration of all students of the snow from the earliest times to the present. They far transcend in beauty, diversity and perfect symmetry the crystals of any mineral species.

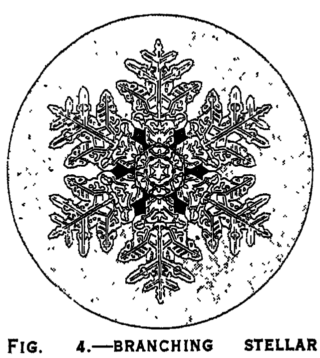

FIG. 4.—BRANCHING STELLAR FORM OF SNOWFLAKE, FROM MEDIUM HEIGHT CLOUDS

The conditions under which the snow crystals form is unique. They crystallize while floating about unsupported in a fluid, the air, of small and varying density. This permits the atoms and molecules of which snow, like all other crystals, is built a much greater freedom of movement while arranging themselves in crystal form than is possible when most crystals are formed. Often the air and clouds wherein they form are in a state of agitation, and vary within their different parts in density, temperature and water content. Sometimes snow crystallizes among a multitude of uncongealed fluid droplets, called cloud. Contrary to popular belief, however, the true crystals are not made of such, though they may collect and freeze upon them in a white opaque manner, or upon themselves to make granular snow, the "graupeln" of the Germans. True snow crystals are formed directly from the invisible and vastly smaller atoms and molecules of water floating between the cloud droplets. Among the many proofs of this, aside from general considerations, is the fact that scanty snowfalls frequently occur from clear skies.

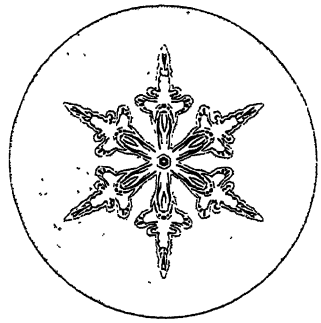

FIG. 5.—STAR FORM OF SNOWFLAKE, LOW CLOUD TYPE

As a result of various unfavourable conditions in cloudland, such as winds, overcrowding, the presence of fluid cloud droplets, etc., the majority of tabular snow crystals fail to attain their natural beauty and symmetry. The most wonderful forms seem to occur within the anterior quadrants of widespread general storms, or during snowfalls that occur between two closely lying storms. The formation of crystals may be determined by some law. It is likely that almost every cyclonic storm produces perfect forms somewhere within its anterior quadrants. There is doubtless a somewhat invariable rule of distribution of the various types of snow within cyclonic storms, columns, or columns and solid plates to one quadrant, granular forms to another, branching crystals to others, etc.

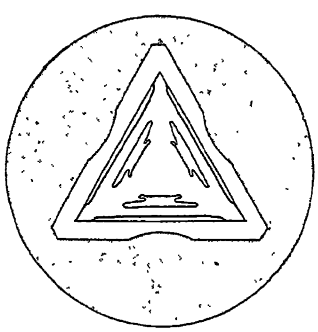

FIG. 6.—TRIANGULAR FORM OF SNOWFLAKE, HIGH CLOUD TYPE, FORMED IN ZERO WEATHER

The feature of chief beauty and interest about the tabular snow crystals, in addition to beauty of outline, is the richness of their interior designs. This richness of interior is due to the presence of minute air tubes and shadings therein, which appear dark when viewed under certain conditions. These interior air tubes and shadings frequently appear in the semblance of tiny rods, dots, lines, etc., often arranged in a marvellously symmetrical manner and outlining geometrical forms. They are caused as a result of the bridging over and inclusion of air as the branches, segments and various adornments grow and unite one to another. Because of this they outline more or less perfectly the various stages of growth and the transitional forms that the crystals assumed in cloudland. Their arrangement doubtless depends largely upon habits of growth. In case of branchy growth they are arranged for the most part at angles of 60° alongside the main and secondary rays. In cases of more solid growth they are often arranged with their greater dimensions in hexagonal order around the nucleus.

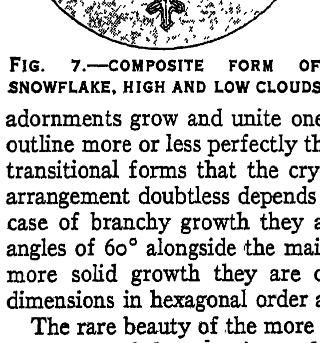

FIG. 7.—COMPOSITE FORM OF SNOWFLAKE, HIGH AND LOW CLOUDS

The rare beauty of the more perfect specimens of snow crystals has attracted the attention and excited the admiration of naturalists from quite early times. We find in the Bible, in the Book of Job, the query, "hast thou entered into the treasures of the snow?"

Many naturalists through the years have made attempts to draw them. During later times many observers, among them Dr. Scoresby and Dr. Glaisher of England, Prof. Squinabol of Italy, Mrs. Chickering of the United States and Dr. Dobrowolski of Poland, made excellent drawings of them. More recently the aid of photography has been employed to portray these evanescent forms. W. A. Bentley of Jericho, Vt., seems to have been the pioneer photomicrographer of snow crystals. Securing the first photomicrographs in 1885, he has continued the work up to the present, making 4,800 photomicrographs, no two alike. In 1903 and soon afterwards Dr. Neuhauss of Berlin, Dr. Nordenskiold of Sweden and Herr Sigson of Russia also made photomicrographs of crystals.

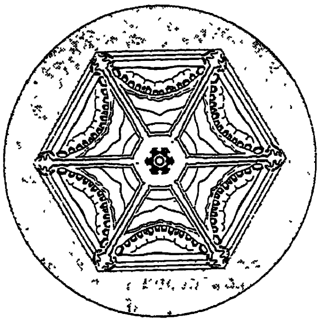

FIG. 8.—SOLID TABULAR FORM OF SNOWFLAKE, HIGH CLOUD TYPE

The formation and deposition of the snow, occurring over so large a portion of the earth's surface and in such enormous quantities as almost to defy computation, constitute a phenomenon of great magnitude and import. The snow forms one of the links in a natural system of continental irrigation, to make possible vegetal and animal life thereon. In winter it conserves the heat of the earth and protects vegetation. It has also served a useful purpose as an aid in transportation, as its icy mantle forms an excellent roadbed over which produce, etc., can be easily drawn in sleds. Snow when compacted and pressed into glacial ice or when melted and converted into streams, rivers, etc., also plays an important part in inland erosion, in the tearing down of mountains and the conversion of rocks into soil.

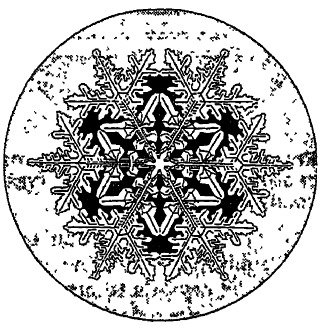

FIG. 9.—BRANCHING FORM OF SNOWFLAKE, MILD WEATHER TYPE

Yet, like the beneficent, life-giving rain, the snow sometimes becomes a destructive agent. The melting of the snows of winter sometimes produces disastrous floods which do great damage. A heavy fall of snow, if accompanied with severe winds, piles the snow into deep drifts along highways and railroads, thus delaying traffic. Not the least of the destructive effects of the snow is the breaking of trees, telephone poles, etc., by the weight of a damp, heavy fall of snow upon them. In mountain regions the snow sometimes accumulates so deeply upon the sides of mountains that great masses break off and descend as destructive avalanches into the valleys, doing great damage and sometimes burying and destroying whole villages. (W. A. BEN.)

SNOWDEN, PHILIP (1864–), British statesman, was born on July 18, 1864, at Cowling, Yorkshire. Educated at an elementary school, he read widely, and became a clerk in the customs and excise department of the Civil Service. Joining the Independent Labour Party in the year after it was founded (1893) he became one of its most effective speakers and, in 1903, and again in 1917 its chairman. He was a member of the I.L.P. for 34 years, but resigned his membership in Dec. 1927, giving as his reason his conviction that the body ought to be merged in the Labour Party and that its continued separate existence was neither desirable nor necessary. His first parliamentary attempts, for Keighley and Blackburn, failed, but, in 1906, he was returned for Blackburn as Labour M.P. In the House he at once made his mark, notably on financial matters. When war broke out in 1914 he was in Australia. On his return he at once ranged himself with J. R. MacDonald and shared much of the latter's unpopularity. Defeated in the 1918 election, he won Colne Valley for Labour in 1922, and held the seat with increased majorities in 1923 and 1924. His appointment as chancellor of the exchequer in MacDonald's cabinet was a matter of course.

In his budget, introduced in April 1924, while limited by the commitments of his predecessor, Snowden endeavoured to relieve the burden of taxation on the poor by his reduction in the food duties, and by making provision, in his contingent Old Age Pensions Act, for the removal of the oppressive features of the thrift disqualification. At the same time, he stood fast by his free trade principles and repealed the McKenna duties on imported motorcars, clocks, musical instruments, etc.; he also terminated the duties imposed under the 1922 Safeguarding of Industries Act. Later in the session he introduced plans of constructive work designed to relieve the prevalent unemployment. At the London conference in July–Aug. 1924, he took charge of the discussions with the bankers which ended in the successful flotation of the German loan in October of that year. Snowden became chancellor of the exchequer for the second time in June 1929.

Snowden's power, both in the Labour movement and outside, was due as much to gifts of character as of brain. As a speaker, he was equally powerful both as a private member in opposition and as a minister. Most of his life was spent in the service of Socialism; he was also a powerful advocate of the emancipation of women and of temperance. In the promotion of these causes, as in his work for peace and in his opposition to Communism, he was notably assisted by his wife, herself a speaker and writer of wide appeal. He was member of the Liquor Control Board during the War, and served on royal commissions on the civil service, canals and venereal disease.

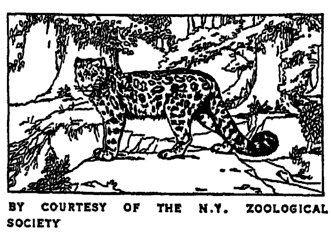
He is the author of various books, among them *A Socialist Budget* (1907); *A Living Wage* (1912); *Socialism and Syndicalism* (1913); *Wages and Prices* (1920); *Labour and National Finance* (1920); *Labour and the New World* (1921).

SNOWDON (*Wyddfa,* view-place; *Eryri,* eagle-place), the highest peak in Wales, formed principally of Ordovician volcanic rocks, slates and grits. (*See* H. Williams, in *Quart. Journ. Geol. Soc.,* 1927, p. 346.) It consists of five "arêtes" converging on the summit, with cirques (*q.v.*), which contain small lakes between them. Surrounding the peak are the Llanberis pass (*q.v.*), Aberglaslyn pass and the Rhyd-ddu pass. Several lakes occur in the valleys rising up to these passes. A rack-and-pinion railway (opened 1897) ascends from Llanberis to the summit ($4\frac{3}{4}$ miles).

See, for full description, *Mountains of Snowdonia* (1925).

SNOWDROP, *Galanthus nivalis,* the best known representative of a small Old World genus of the family Amaryllidaceae, all the species of which have bulbs, linear leaves and erect flower-stalks, destitute of leaves but bearing at the top a solitary pendulous bell-shaped flower. The snowdrop is a doubtful native of Great Britain, but is largely cultivated for market in Lincolnshire. Other distinct species of snowdrop are the Crimean snowdrop, *G. plicatus,* with broad leaves folded like a fan, and *G. Elwesii,* a native of the Levant, with large flowers. All the species thrive in almost any soil or position.

SNOW-LEOPARD or **OUNCE** (*Felis uncia*), a large member of the cat family, from the high mountain regions of Central Asia. It resembles the leopard in general conformation, but has longer fur, grey in colour, marked with large dark rosettes. The head and body are about 4ft. 4in. long, the tail 3ft., and the height 2ft. This animal lives among rocks, and preys upon wild sheep and goats, large rodents, and birds. It even kills ponies.



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

SNOW LEOPARD OR OUNCE (FELIS UNCIA) A NATIVE OF CENTRAL ASIA

SNOW-LINE, the line above which the snows remain unmelted in the form of a permanent snowfield. Snow-fields occur in any latitude at sufficiently high altitudes, or at any altitude in sufficiently high latitudes. About 78° latitude the snow-line reaches sea-level; in lower latitudes it shows a progressive rise, but many factors in addition to temperature influence its height, *e.g.,* total snowfall, humidity of atmosphere and aspect. In Lapland it is about 4,000 ft. above sea-level; in the Alps about 9,000 ft.; on the south side of the Himalayas about 13,000 ft., but on the

north side over 16,500 ft.; on the east side of the equatorial Andes about 16,000 ft., but 18,500 ft. on the western side.

SNOW-PLANT (*Sarcodes sanguinea*), a North American saprophytic herb of the family Pyrolaceae, so named because it often blooms in moist places in the vicinity of melting snow. It is closely allied to the Indian-pipe (*q.v.*) and, by reason of its bright red or crimson colour throughout, presents a striking appearance. It grows in pine woods on mountain slopes from southern Oregon to Lower California and eastward to Nevada. The single, fleshy, scaly stem, 6 to 15 in. high, rises from a ball of brittle roots and bears at its summit a cylindrical cluster of nodding, bell-shaped crimson flowers.

SNOW PLOUGH. A contrivance for clearing rail tracks of snow. The oldest and most common form is the wedge plough, with a sharp prow. The rotary plough is the most powerful machine. It burrows into the drifts after the manner of an auger, and whirls the snow clear of the track. The rotary element consists of a large fan-like wheel driven by an engine on a truck. As a rule the truck is non-propelling, being pushed by a locomotive. The scoop is about 11 ft. in diameter, and the blades or knives are made of cast-steel; a large wheel may weigh 12 tons.

SNOW-SHOES, a form of footgear devised for travelling over snow. Nearly every American Indian tribe has its own particular shape of shoe, the simplest and most primitive being those of the far north. The Eskimos possess two styles, one being triangular in shape and about 18in. in length, and the other almost circular. Southward the shoe becomes gradually narrower and longer, the largest being the hunting snow-shoe of the Crees, which is nearly 6ft. long and turned up at the toe. Of snow-shoes worn by people of European race that used by lumbermen is about 3½ft. long and broad in proportion, while the tracker's shoe is over 5ft. long and very narrow. This form has been copied by the Canadian snow-shoe clubs, who wear a shoe about 3½ft. long and 15 to 18in. broad, slightly turned up at the toe and terminating in a kind of tail behind.

Snow-shoes are made of a single strip of some tough wood, usually hickory, curved round and fastened together at the ends and supported in the middle by a light cross-bar, the space within the frame thus made being filled with a close webbing of dressed caribou or neat's-hide strips, leaving a small opening just behind the cross-bar for the toe of the moccasined foot. They are fastened to the moccasin by leather thongs, sometimes by buckles. The method of walking is to lift the shoes slightly and slide the overlapping inner edges over each other, thus avoiding the unnatural and fatiguing "straddle-gait" that would otherwise be necessary. Immoderate snow-shoeing leads to serious lameness of the feet and ankles which the Canadian *voyageurs* call *mal de raquette*. Snow-shoe racing is very common in the Canadian snow-shoe clubs, and one of the events is a hurdle-race over hurdles 3ft. 6in. high. Owing to the thick forests of America the snow-shoe has been found more suitable for use than the Norwegian *ski* (*q.v.*) which is much used in less-wooded districts. (X.)

The United States.—While enjoying practically the same snow conditions as Canada, the United States snow belt has never taken up the organization of its interest in snow-shoeing in a great number of specialized snow-shoe clubs. Compared with the snow-shoe clubs of Canada, with their well-known snow-shoe competitions, the United States interest in snow-shoeing is more casual.

Still the snow-shoeing interest in the United States is considerable; it usually ties itself to a general out-of-door winter programme. The men's and women's colleges in the snow belt conduct snow-shoe cross-country races, obstacle races and snow-shoe hikes. Dartmouth college has an annual inter-collegiate snow-shoe contest in which Canadian colleges figure. Lake Placid, N.Y., conducts club and inter-collegiate snow-shoe contests. Practically every winter carnival held in the United States includes snow-shoe obstacle races and cross-country races.

The Appalachian club of the United States promotes mountain climbing on snow-shoes. The Dartmouth Outing club members each year make an ascent of Mt. Washington on snow-shoes. The Intercollegiate Winter Sports Union includes snow-shoe dashes and similar races in its programmes.

See *Lake Placid Club Winter Sports; Appalachia,* organ of the Appalachian Club. (F. K. B.)

SNUFF, the name of a powdered preparation of tobacco used for inhalation (*see* TOBACCO). The practice of inhaling snuff became common in England in the 17th century, and throughout the 18th century it was universal. At first each quantity was fresh grated (Fr. *râper*), whence the coarser kinds were later known as "rappee." This entailed the snuff-taker carrying with him a grater; early 18th-century graters made of ivory and other material are in existence. The art and craft of the miniature painter, the enameller, jeweller and gold- and silver-smith was bestowed upon the box. The humbler snuff-takers were content with boxes of silver, brass or other metal, horn, tortoise-shell or wood. The mull (*q.v.*), a silver-mounted ram's head, is a large table snuff-box.

SNYDERS, FRANS (1579–1657), Flemish painter of animals and still life, was born at Antwerp, where he was baptized on Nov. 11, 1579 and where he died on Aug. 19, 1657. In 1593 he was studying under Pieter Breughel the younger, and afterwards under Hendrick van Balen, the first master of Van Dyck. He visited Italy in 1608. On Oct. 23, 1611 he married Margaretha de Vos, the sister of the painters Cornelis and Paul de Vos. He devoted himself to painting flowers, fruit and subjects of still life, but afterwards turned to animal-painting, and executed with the greatest skill and spirit hunting pieces and combats of wild animals. His composition is rich and varied, his drawing correct and vigorous, his touch bold and thoroughly expressive of the different textures of furs and skins. Rubens frequently employed him to paint animals, fruit and still life in his own pictures, and he assisted Jordaens in a similar manner. In the lion and boar hunts which bear the name of Snyders the hand of Rubens sometimes appears. He was appointed principal painter to the archduke Albert, governor of the Low Countries, for whom he executed some of his finest works. One of these, a "Stag-Hunt," was presented to Philip III., who commissioned the artist to paint several subjects of the chase. The Prado museum, Madrid, is rich in the works of Snyders; others may be seen in the galleries of London, Hampton Court, Paris, Antwerp, Brussels, Dresden, Munich, Leningrad and Vienna.

SOANE, SIR JOHN (1753–1837), English architect and art collector, was born on Sept. 10, 1753 at Whitchurch, near Reading, and died in Lincoln's Inn Fields on Jan. 20, 1837. He came of a family whose name of Swan he altered to Soan or Soane. His talent as a boy attracted the attention of George Dance, junior, the architect, whose pupil he became. He won the Royal Academy's silver (1772) and gold (1776) medals, and a travelling studentship, and went to Italy to study (1777–1780). Returning to England he began to practice as an architect, and in 1784 married a rich wife. He became architect to the Bank of England, which he enlarged and rebuilt in the Roman Corinthian style and did other important public work. He also erected many country houses, the designs for which he published in a book in 1788. He became an A.R.A. (1795), R.A. (1802) and professor of architecture to the Royal Academy (1806). In his house in Lincoln's Inn Fields he brought together a valuable antiquarian museum (now the Soane Museum), which in 1835 he presented to the nation with an endowment.

See A. E. Bullock, *Sir John Soane, His Life, Work and Influence,* Archit. Assoc. Notes xx. (1905); H. J. Birnstingl, *Sir John Soane* (1925); A. T. Bolton, *The Portrait of Sir John Soane* (1927).

SOAP, a chemical compound, or mixture of chemical compounds, resulting from the interaction of fatty oils and fats with alkalis, *i.e.,* the salts of the fatty acids. In a scientific definition, the compounds of fatty acids with basic metallic oxides, lime, magnesia, lead oxide, etc., should also be included under soap; but, as these compounds are insoluble in water, while the very essence of a soap in its industrial relations is solubility, it is customary to use the term "soap" for the compounds of fatty acids with potash, soda and ammonia; the water-insoluble soaps of the other bases may be termed "metallic soaps" or "plasters."

Soap appears to have been first made by boiling goat's tallow

and causticised beech ashes (Pliny); the resulting soft potash soap was converted into hard soda soap by treating the paste repeatedly with salt. Later wood ashes were replaced by soda ashes from sea-plants, kelp, barilla, etc. In the 13th century the industry was introduced from Italy and Germany into France, and the manufacture of olive oil soap established at Marseilles. In England the trade flourished from the 14th century; during the reign of Charles I. a monopoly of soap-making was farmed to a corporation of soap-boilers in London. From 1712 to 1853 an excise duty ranging from 1d. to 3d. per lb. was levied on soap made in the United Kingdom; despite this heavy impost (equal, when 3d., to more than the cost of the soap) the industry expanded with considerable rapidity. In 1793, when the duty was 2¼d. on hard, and 1¾d. on soft soap, the revenue yielded was a little over £400,000; in 1815 it was almost £750,000; in 1835, when the duty was levied at 1½d. and 1d. respectively (and a drawback allowed for soap used in manufactures) the revenue approached £1,000,000. In 1852, the last year in which soap was taxed, it amounted to £1,126,046, with a drawback on exportation of £271,000.

The processes and extent of the manufacture were revolutionized during the first half of the 18th century as a result of Chevreul's classical researches on the constitution of oils and fats, and by the introduction of the Leblanc process (invented 1791) for the manufacture of soda from brine. It was some time, however, before manufacturers could be induced to substitute the new article for natural barilla soda; in fact, Muspratt, the founder of the English alkali industry, had to distribute gratis scores of tons of the manufactured soda in order to popularise the material. The progress of the industry was assisted by further improved processes of caustic alkali manufacture, and by the utilisation of coconut, palm and other oils to supplement the tallow and olive oil exclusively used in older times.

Chemistry of Soap.—Previous to Chevreul's researches on the fats (1811–1823) it was believed that soap consisted of a simple binary compound of fat and alkali. Claude J. Geoffroy in 1741 pointed out that the "fat" (actually fatty acids) recovered from a solution of soap by neutralisation with mineral acid, differed from the original fatty substance by dissolving readily in alcohol, in which ordinary fats were insoluble. The significance of this fact was overlooked, and equally unheeded was a not less important discovery by Scheele in 1783. In preparing lead plaster by boiling olive oil with oxide of lead and a little water—a process palpably analogous to that of the soap-boiler—he obtained a sweet substance which, termed by him "Ölsüss" (*principium dulce oleorum*), is now known as glycerin. These discoveries of Geoffroy and Scheele formed the basis of Chevreul's researches by which he established the constitution of oils and the true nature of soap. In the article OILS it is pointed out that all fatty oils and fats are mixtures of glycerides, *i.e.*, of compounds (esters) of the trihydric alcohol glycerol (glycerin) and some fatty acid such as palmitic acid, etc. Under suitable conditions, the decomposition of a glyceride into acid and glycerin ("hydrolysis" or "saponification") takes place when the glyceride is distilled in superheated steam, or boiled in water with a certain proportion of caustic alkali. In the latter case the alkali combines with the fatty acid to form its potash or soda salt (soap), thus:

$$\underset{\text{Palmitin}}{C_3H_5(O.CO.C_{15}H_{31})_3} + \underset{\text{Caustic Soda}}{3NaOH} = \underset{\substack{\text{Soap}\\ \text{(Sodium Palmitate)}}}{3\,NaO.CO.C_{15}H_{31}} + \underset{\text{Glycerin}}{C_3H_5(OH)_3}$$

(It may be remarked that the term "saponification" is used scientifically to denote the decomposition by water—hydrolysis—of an ester, in this case a glyceride, into its constituent alcohol and acid; it does not necessarily connote the formation of "soap".)

The most important constituent fatty acids of the natural fats are palmitic, stearic and oleic acids, and it is sufficient to regard these as the principal fatty bodies concerned in soap-making. The general characters of a soap are a certain greasiness to the touch, ready solubility in water, with formation of more or less viscid solutions, which on agitation yield a tenacious froth or "lather," and an indisposition to crystallize: hot concentrated solutions are slimy and, on cooling, set to jellies. Soaps give an alkaline reaction in water solution (due to hydrolysis) and have an acrid taste: in the pure condition—a state never reached in commercial practice—they have neither smell nor colour. Almost without exception potash soaps, even if made from the solid fatty acids are "soft" (glutinous jelly) and soda soaps, including those made from the fluid olein are hard; there are, however, considerable variations in consistency according to the prevailing fatty acids. Almost all soda soaps are precipitated from aqueous solution by the addition of sufficient common salt. Potash soap, with the same reagent, undergoes double decomposition—a proportion being converted into the soda soap with the formation of potassium chloride.

Soaps can occur in several physical modifications. In the condition of "neat soap" as found in the pan (containing 30% water) soda soaps display the phenomenon of anisotropy or "liquid crystals." As the neat soap cools the characteristic long thin "curd fibres," which exhibit many of the properties of true crystals, grow from and through the mass of fluid crystals. Transparent solid soaps (*q.v.* below) are supercooled solid solutions in which crystallisation has been retarded; they are optically homogeneous (isotropic) and may be true colloidal gels. In old specimens crystallisation of fibres may occur, and the formation of these can be induced by "seeding" with fibre crystals. The "*figging*" (growth of irregular opaque masses) in potash soft soap is due to the crystallising out of harder constituent soaps of the mixture, the bulk consisting of fluid crystals and isotropic jelly. From alcoholic solutions of pure soaps, such as sodium palmitate, true crystals can be obtained.

In aqueous solution soap was originally regarded as an ordinary colloid; the solution, however, possesses a high electrical conductivity, which is normally associated with electrolytes. These apparently conflicting facts are reconciled by McBain (to whom much of the recent physico-chemical investigation of soap solutions is due) by the theory of "colloidal electrolytes," postulating the occurrence of the "ionic micelle," or multiply-charged and heavily hydrated colloidal aggregate of ionised molecules. In alcoholic solution, soap behaves as a simple unhydrolysed non-electrolyte. When dissolved in water, soap suffers hydrolysis to an extent dependent on the dilution, resulting in the precipitation of acid soaps (*e.g.*, sodium hydrogen palmitate), and the liberation of a small amount of free alkali and infinitesimal quantities of free fatty acid.

Detergent Power.—The detergent power of soaps was originally attributed to the alkali formed by hydrolysis (Berzelius), but recent work has proved (McBain, Hillyer and others) that the amount of such alkali is far too minute to account for the cleansing properties; moreover, hydrolysis is greater in cold dilute solution, whereas the detergent power of hot relatively concentrated solutions is far superior. The detergent action is now considered to be due to the soap itself, and principally a result of its physical characters. Spring considers that soap forms a "colloidal absorption compound" with the dirt, whereby the latter is hindered from re-deposition on the fabric whence its removal was facilitated by the low surface tension between soap solution and grease. In support of the theory, he cites the observation that lamp-black suspended in soap solution is not removed by filtration. It has also been suggested that the soap "lubricates" the dirt particles, rendering them less adherent and more easily removable by rubbing, and that soap may exert a solvent or emulsifying action on oils and grease in the dirty fabric.

The concentration of a soap solution has considerable influence on the cleansing power; as a rule, the best results are obtained with 0·25–0·5% solutions (laundry practice).

Soap Materials.—Almost any fat can be utilised in the manufacture of soap, the choice being determined by the price of the oil or fat and the quality and type of soap required. The most important of the animal oils used are tallow and grease (toilet soap), and of the vegetable oils, cottonseed, coconut (cold-

process, marine soaps) palm, castor (transparent soaps) and olive (textile, toilet soaps) oils. Sulphur extracted olive oil is very suitable for the manufacture of potash soft soaps for the textile industries. Linseed oil is the principal ingredient of soft soaps for other purposes. This is infrequently used in America, soya bean or comoile being more commonly substituted. Rosin (the residue from the distillation of crude oil of turpentine) is an important ingredient of yellow ("primrose") household and washer soaps. Lower grade soaps (brown) are made from bone fat, kitchen grease and low grade tallows. As a result of the increased demand for first quality oils for edible purposes, there has been considerable employment recently of hardened oils *e.g.,* whale, soya-bean, etc. For *alkalis,* caustic soda is usually employed; sodium carbonate may be substituted if the soap is to be made from fatty acids. Caustic potash is used for the production of soft soaps.

Manufacturing Processes.—The processes for the manufacture of soap fall into three classes: formation of soaps by (1) *Neutralization of fatty acids with alkali (caustic or carbonate).* This is not strictly "saponification" but a simple combination similar to the formation of rosin soap. The method enables the manufacturer to employ fats from which the glycerin has been removed by other methods of hydrolysis, and such materials as the "oleine" (liquid fatty acids) which is a by-product of the candle-stearine industry, and "soap-stock fatty acids" recovered from the refining of fatty oils. The soap is made by pouring the melted fatty acids slowly into the preheated alkali solution in the soap-pan, the mass being kept boiling by steam to avoid the formation of lumps ("bunching"). The boiling is continued and the soap "finished" as in the boiling process (*see* below). The production of soft soap by this method has increased latterly, especially on the Continent, as thereby loss of glycerin by inclusion in the soap is avoided. A slight advantage gained by using the cheaper sodium carbonate instead of caustic alkali is counterbalanced by the additional care needed to avoid losses by boiling-over due to the evolution of carbon dioxide. The various methods of saponification or fat-splitting, by which fatty acids may be prepared from oils may be briefly mentioned.

In the Krebitz process lime soaps are formed, washed free from glycerin, and the fatty acids liberated by treatment with mineral acid. The processes of hydrolysis by steam in the presence of catalysts (lime and magnesia in the *autoclave process,* sulphonated fatty acid compounds in the *Twitchell method*) are outlined in the article CANDLE. The only other fat-splitting process of importance (principally used in India) is the *fermentation process,* in which hydrolysis is obtained by the action of the ferment lipase, contained in considerable amounts in castor seeds. The process is a reproduction of the natural hydrolysis of oils by living organisms. The ferment is added, in the form of an emulsion of freshly crushed castor seeds, to the oil to be saponified, and the whole is maintained at a temperature of about 25° C until the reaction ceases. The fatty acids from the various processes are separated by settling, and washed. In most cases the acids are purified by wet distillation with superheated steam. (2) *Saponification of oils and fats by caustic alkalis.*—(A) by processes whereby the glycerin is *not* recovered from the soap: including the production of (i.) *cold process soaps,* (ii.) *hydrated (semi-boiled) soaps* and *soft soaps.* (B) by processes whereby the glycerin is recovered in lyes separated from the soap: exemplified by the *boiling process* for the production of *curd* and *"fitted"* or *"settled"* soaps, which is the method employed at present on the largest scale. (*See* below.) (3) *Formation of soap by double decomposition.*—This method is illustrated by the oldest process of hard soap manufacture, namely, the production of soda soap by double decomposition of potash soap by salt. In another process, the soaps of the alkaline earths are made by saponification of fats with lime, magnesia, etc.; these are decomposed by sodium carbonate forming the soda soap and precipitating the carbonate of the metal. These processes are very little employed in modern practice, and are not used in America.

(2) A (i.) **Soap-making by the Cold Process.**—This depends on the fact that fats of the coconut oil group are very readily saponified by relatively concentrated solutions (about 30%) of caustic alkali (*lyes*) at low temperatures. Further, tallow when admixed with these oils may be saponified under the same conditions. The process is simple and consists in melting the fats at about 60° C (or, in some cases, at a lower temperature) and running exactly sufficient lye with constant stirring; the mixture is thoroughly stirred ("crutched") until it thickens (perfume, colouring matter, etc., may be crutched in as required) and then discharged into the cooling "frames" which may be lagged to prevent over-rapid cooling. The process of saponification completes itself in the frame with the evolution of considerable heat; the soap is ready for distribution in two or three days. The method has the advantage of rapidity, and the extreme simplicity of the plant renders it valuable for districts where it is difficult to obtain or transport machinery. The disadvantages are that the glycerin (unnecessary except in toilet soaps) is retained in the soap and its value lost, and that it is difficult to ensure complete saponification: excess fat renders the soap liable to rancidity, but, with modern methods of scientific control, the presence of excess alkali, which was formerly regarded as the great drawback of cold process soaps, can be avoided. The process finds considerable application in the manufacture of the cheaper toilet soaps and transparent soaps (*q.v.*).

(2) A. (ii.) **Hydrated (Semi-boiled) Hard and Soft Soaps.**—These are made by boiling the fatty material and the caustic lye with open steam until saponification is complete. (In the case of soft soap a little potassium carbonate—"pearl ash"—is added to improve the appearance.) The mixture is boiled down by closed steam to the required concentration and the soap framed or packed into tins (soft soap). The use of soda yields hard soaps while potash produces jelly-like translucent *soft soaps.* No lye is separated and no glycerin recovered. If soft soap is made entirely from linseed oil the transparency is retained at low temperatures; if the stock contains notable proportions of cottonseed or maize oils the soap is liable to become dull ("blind") in winter. The use of a proportion of tallow or of caustic soda gives rise to stellate clusters of crystals of harder soaps (*figging*). Marine soaps and the bulk of soft soaps are manufactured by this process, which is more suitable for fats of high free fatty acid content than the cold process.

Attempts have been made to reduce the time necessary for saponification by hydrolysing the fats under pressure, and a continuous process has been suggested; these methods, however, have not yet attained commercial practice.

To obtain a high-grade product by these methods of manufacture it is essential that all the materials employed shall be of good quality; for, necessarily, all that enters the soap-pan appears in the final product.

(2) B. **Boiled, Settled or Fitted Soaps.**—In this process the stock (fats) is saponified with an indefinite amount of caustic soda; the excess alkali, together with the glycerin of the fats is recovered in the lyes which are separated from the soap by "graining." Soap-pan charges vary from 10–30 tons as a rule, and the process is conducted in the following stages ("changes").

(1) *Pasting or Saponification.*—The melted fats are introduced into the soap-pan, a weak caustic soda lye (about 10%) is added and the whole boiled with open steam from perforated coils. The injected steam suffices to keep the soap masses in a state of vigorous agitation. As saponification proceeds, stronger lye is added with continued boiling until saponification is almost complete, as judged by the taste and texture of the emulsion formed. In order to break this emulsion and to separate the lye, the paste is subjected to (2) *Graining* or salting out. Boiling is continued and salt is sprinkled on the paste, or brine added, until the soap, which is insoluble in salt solution, separates. On allowing the mixture to settle, the soap rises to the surface, floating as a curdy heterogeneous mass of "open grains" enclosing small amounts of lye. The almost neutral brine solution, termed *"spent lye,"* which contains the glycerin derived from the stock, separates below. The spent lye is run off from the bottom of the pan and subsequently treated for glycerin (*q.v.*) recovery. In the case of coconut and palm-kernel oils, whose soaps are soluble in salt

solutions (whence their use at sea as *"marine soaps"*), the graining or "cutting" of the soap is accomplished by the use of strong caustic soda as in the clear boiling change described below. After graining the soap is just "closed" (grainy structure dissolved) by the addition of water, and the next operation (3) of *"making the soap"* or *"boiling on strength"* (*"clear-boiling,"* or *"strength change"*), is performed by boiling up with excess of strong lye which again opens the soap. The mixture is boiled with continued additions of lye until the last traces of fat are saponified, *i.e.,* until permanent "strength" or alkalinity is observed and the soap remains "open." After settling for several hours, the *"half-spent lye"* settles out underneath the soap. This contains considerable quantities of alkali and a small amount of glycerin; it is withdrawn and used for the early stages of the pasting of a fresh batch of material.

Curd Soap.—The soap may be removed and framed at this stage; the product is known as genuine "curd" soap, and usually contains traces of soda and salt.

After clear boiling it is usual practice to give the soap one or two brine washes to remove entangled lye. The soap then undergoes (4) *finishing* or *fitting* (in the U.S.A. called *"settling change"*), which consists in once more closing the soap by the addition of just sufficient steam and water, and boiling until the soap is brought to the right condition of hydration and openness. The workman in charge adjusts the coarseness of the "fit" according to the type of soap handled; the art consists in bringing the soap to such a condition that impurities shall separate in the subsequent "settling" (3–7 days).

The material in the pan settles into four distinct layers: (1) a "fob" or crust of solidified soap foam at the surface, which is skimmed off and added to the next batch fitted: (2) a layer of clean *"neat soap"* ("settled" soap) comprising 75–80% of the contents of the pan, testing 63–64% fatty acids and containing about 30% of water. Such a soap is termed *"genuine* soap," since in practice it is not possible to produce a commercial soap in the pan (without drying) containing less water: (3) a layer (about 15–20% of the total) of darker discoloured soap termed *"nigre,"* containing the separated impurities, chiefly metallic soaps, (of iron, etc.), excess alkali and salt. Nigres from several batches may be united and worked up separately as a lower quality soap, but are usually added to the charge for the next lower grade of soap. Bleaching of the nigres is occasionally practised: (4) a small amount of alkaline liquor containing sodium carbonate, chloride and traces of hydroxide.

In America the practice of skimming off the crust is not common. The "genuine" soap, or settled soap, is pumped off, bringing the crust and the nigre together. Nigres are also generally added to the next charge of the same grade of soap rather than to a lower quality soap. If the kettle to which the nigre is added appears too dark, it is "pitched" or settled so that the nigre from this contains the most of the impurities. This nigre, only obtained once or twice a year, is added to a soap of lower quality.

The pan is "cleansed" by running off the liquid hot neat soap into frames, or into crutching pans for the addition of rosin soap (washer soaps), or medicaments, perfume, colouring matter, etc. (toilet soaps, *q.v.*), or for *"running," "liquoring"* or *"filling"* (household soaps). *Running* or *liquoring* genuine soap consists in the addition of alkaline solutions; soda and sodium silicate are commonly used, and pearl ash is often added to improve the appearance. These materials exert a certain cleansing action and cannot be considered as sheer adulterants such as the "fillers," of which sodium sulphate, talc, chalk, starch, barytes, etc., are typical. In the presence of silicate and salt it is possible to produce a firm soap containing more than the 30% of water characteristic of genuine soap. Rosin may be added to the charge, preferably during the strength boil, but it is more usual to saponify it separately, and to add the resultant rosin soap in the crutching pan; its presence imparts good lathering power to the soap and it possesses a fair detergent action.

After crutching, the soap is run into the frames to cool. Machinery to effect more rapid cooling has been introduced recently and has an increasing vogue, especially on the Continent; the product of rapid chilling is not quite identical with, nor so satisfactory for some uses as, the soap obtained by slow spontaneous cooling.

The cold soap is cut into bars and slabs (by wires stretched on frames). The bars are air-dried for a day, to form a sort of crust, which is sufficiently firm to enable the brand, etc., to be stamped on the tablet. This process completes the manufacture of soap for household and technical use.

Toilet Soaps.—These may be made as already described by the cold-process, or be prepared from a neat settled soap by the simple crutching in of perfume, colouring matter, etc., before framing. Similar soaps are made by *remelting* a genuine or curd soap in special pans for the admixture of perfumes, etc. In this method only cheap perfumes are employed, as considerable quantities are necessary to compensate for the loss by evaporation from the hot mixture.

The bulk of high-grade toilet soap is made from settled soap by the *milling process,* originally introduced from France. The soap from the frames is cut into bars and reduced to fine shavings or chips, which are exposed to warm air in drying chambers until the moisture content (originally 30%) is reduced to about 15%. The chips are mixed with perfume, colouring matters, glycerin, or superfatting material, such as lanolin, etc., as required, and "milled" by passing through a series of smooth granite rollers. On leaving the rolls the soap sheet is again shredded and re-milled, and the process repeated several times until the material is homogeneous. The soap ribbons are then forced through a "plodder," a machine which compresses and extrudes the soap through a heated nozzle in the form of a bar with a glossy surface. The bar is cut into short blocks, which are finished for distribution by moulding in stamping machines to the shape required for the final tablet.

Elaborate blends of essential oils (*q.v.*), both natural and synthetic, are used for the perfuming of soaps. It is necessary to select such perfumes as will not discolour or decompose in the presence of the materials of the soap. Many brands of toilet soap are associated with particular perfumes, *e.g.,* "Brown Windsor" is characterised by the odour of oil of cassia. Vegetable colouring matters, such as chlorophyll, are popular, but the coal-tar dyes have also large application. *Shaving soaps* should be made from a good tallow base; usually a mixture of potash and soda is used for the saponification in order to obtain a suitable consistency. Occasionally gum tragacanth is added to increase the stability of the lather. *Floating soaps* are made by stirring kapok fibre or, more generally, air into the soap, so that on cooling the tablet possesses a density less than that of water. A *solid transparent soap* may be prepared by the cold process by the use of a mixture of coconut and castor oils, with the addition of small amounts of rosin, glycerin, alcohol or sugar (all bodies containing one or more hydroxyl groups in the molecule). Excess of glycerin renders the soap liable to sweating, and it is usual to add rosin and sugar syrup to obtain transparency. Better quality transparent soaps are produced by the older method of dissolving a settled soap, usually a "primrose" or tallow-rosin base in alcohol. The solution is concentrated until the mixture sets to a solid cloudy mass on cooling. This is cut and moulded into tablets, and these are stored in drying chambers for 3–6 months. The bulk of the alcohol evaporates and the soap gradually becomes clear and transparent.

Household and "Washer" Soaps.—The best grade household soaps consist of tallow-rosin, curd and settled soaps (*e.g.,* 20% rosin, 40% tallow, 40% coconut, cottonseed oils, etc.). Lower grades are made from bone-fat, kitchen grease and other low-grade oils and fats. All qualities are made, from a genuine soap (63% fatty acids) through all gradations of carbonated, silicated, "filled" and "run" soaps down to "scouring" soaps, which may contain as little as 10% fatty acids.

Soap powders consist of powdered dried soap admixed with sodium carbonate and silicate, and frequently oxidising agents such as persulphates or perborates.

Mottled Soaps.—If somewhat low-grade fatty material, *e.g.,* kitchen-grease, low quality olive oils, is used in the preparation of curd soaps, it is necessary to finish on a stronger lye, produc-

ing a coarse-grained curd. By careful control of the clear-boiling stage, followed by slow cooling in the frames the soap crystallises fractionally: harder soaps separate first, the more liquid portions solidifying later are segregated into translucent veins in which are trapped any impurities (usually coloured) such as iron soaps, etc. The crude barilla soda used in the earlier days of the soap industry frequently contained impurities of a blue colour, causing a blue "mottle." If excessive water were added to the soap this marbling was not produced; consequently the presence of "mottle" was regarded as a guarantee of a genuine soap. Such a soap is termed *"curd mottled"* or *"genuine mottled."* Now, however, the colour is usually supplied by the deliberate addition to a curd soap of *e.g.*, ultramarine (blue) or manganese dioxide (black mottle). Further, it has been found possible to produce "artificial mottled" soaps from heavily liquored low grade soaps; the presence of mottle, therefore, can no longer be accepted as an indication of genuineness.

Textile Soaps.—Soap is used to a large extent in the manufacture of silk, woollen and cotton goods. In the preparation of woollen goods it is required at three stages: scouring of raw wool to remove the wool-grease, scouring the yarns and cloth after oiling, in fulling and milling. Soap is used for "de-gumming" raw silk, for cleansing silk and cotton before and after dyeing, and in the dye-bath, as well as for calico printing. For all these purposes a potash-olive oil soap is to be preferred; on account of the expense, however, it is frequently replaced for cheaper goods by soda soaps, and by soaps made from kitchen grease, bone-fat, palm and ground-nut oils, etc. The absence of free caustic alkali is imperative for all purposes; for de-gumming silk and for cleaning cotton slight alkalinity (due to free carbonate) is permissible. The soaps should be readily soluble and should not contain rosin, or maize or cottonseed oils, which contain substances that are liable to act as resists to the dyes. Ammonia soaps and soaps made from sulphonated oils have recently been introduced for wool scouring.

Medicated Soaps.—Disinfectant soaps are manufactured by the addition of disinfectants such as coal-tar phenols (*e.g.*, carbolic acid), birch tar, borax, thymol, icthyol, mercury salts, etc., before framing or during the milling process. Lysol preparations consist of soap solutions containing cresol. Soap itself possesses a slight germicidal action and apparently enhances the disinfectant power of certain other substances such as thymol, etc. Heavily medicated soaps are used in the treatment of certain skin diseases, as also the metallic soaps of zinc, copper, mercury and lead. Two preparations of hard soap (sodium oleate) are used in medicine: (1) *Emplastrum saponis,* made with lead plaster; (2) *Pilula saponis composita,* which contains one in five parts of opium. A preparation of the green soft olive oil soap, known as *opodeldoc* (*Linamentum saponis*) is a domestic remedy for stiffness and sprains. The chief use of hard soap is in enemata; it also forms the basis of many pills. Given in warm water it forms a ready emetic in cases of poisoning.

Metallic Soaps.—Besides their use in pharmacy the soaps of the alkaline earths and heavy metals have extensive application in the arts. Lime soaps are the principal constituents of many lubricating greases; aluminium oleate is used as an "oil thickener" for paint and varnish oils and for waterproofing textiles and paper; dissolved in benzene it forms a paper varnish. The oleates and linoleates and rosinates of lead, cobalt and manganese are used extensively as "driers" for paints and oil varnishes.

SOAP-BARK, the inner bark of *Quillaja Saponaria,* a large tree of the rose family (*Rosaceae*), which grows in Chile. Reduced to powder, it is employed as a substitute for soap, since it forms a lather with water, owing to the presence of a glucoside saponin, which has a marked surface tension action. The same, or a closely similar substance, is found in soapwort (*Saponaria officinalis*), in senega root (*Polygala Senega*) and in sarsaparilla. The saponins are poisonous, having a marked haemolytic (blood-destroying) action. They (with few exceptions) have the general formula $C_nH_{2n-8}O_{10}$, and by the action of dilute acids they are hydrolysed into sugars and sapogenins, which are usually inert pharmacologically.

SOAP PLANTS, the name given to numerous herbs, shrubs and trees which contain the poisonous glucoside saponin. Various parts of such plants form a lather in water and may be used for cleansing purposes, as the soap bark (*q.v.*). Other examples are the soapwort (*q.v.*) or bouncing Bet and the cowherb (*Vaccaria vulgaris*). In the south-western United States various plants called *amole* by the Indians are similarly utilized, especially the small agave (*Agave heteracantha*) and the soap-root (*Chlorogalum pomeridianum*). Other soap plants of the western United States are the zygadene and the sand lily (*qq.v.*).

SOAPWORT (*Saponaria officinalis*), a perennial herb of the pink family, Caryophyllaceae (*q.v.*), called also bouncing Bet, native to Europe and western Asia, common in Great Britain and widely naturalized in North America, often planted in borders and rockeries. It is a stout, smooth, sparingly branched perennial, 2 to 3 ft. high, with lance-shaped leaves and pink or whitish flowers, borne in dense clusters. The leaves and roots contain saponin, which makes a froth with water, and can be used for washing delicate fabrics. (*See* SOAP PLANTS.)

SOBAT, a river of north-east Africa, the most southerly of the great eastern affluents of the Nile. It is formed by the junction of various streams which rise in the south-west of the Abyssinian highlands and north-west of Lake Rudolf. The length of the Sobat, reckoning from the source of the Baro, the chief upper stream, to the confluence with the Nile is about 460 miles. The Baro rises in about 36° 10′ E., 7° 50′ N. at an altitude of some 7,000 ft. The Baro descends the escarpment of the plateau between great walls of rock, dropping 3,000 ft. in 45 miles. It then flows through a narrow gorge at an altitude of about 2,000 ft., the mountains on either side towering 3,000 to 4,000 ft. above the river bed. Just east of 35′ E. the Birbir joins the Baro. Some 40 m. lower down the hills are left behind and the river flows west across a vast plain. From Gambela, a town on its north bank 20 m. below the Birbir junction, the river is navigable by steamers during flood time (June–December) to the point of confluence with the White Nile. In about 33° 20′ E., 8° 30′ N., it is joined by the Pibor. This river issues from the swamp region east of Bor on the Bahr-el-Jebel stretch of the Nile. It is joined from the east and south by various streams from the Kaffa plateau. Of these the chief are the Gelo—which breaks through a gap in the mountains in a series of magnificent cascades—and the Akobo. The Akobo rises in about 6° 30′ N., 35° 30′ E. The whole region of the lower Pibor and Baro is one of swamps, caused by the rivers overflowing their banks in the rainy season. At its junction with the Baro the Pibor is over 100 yd. wide, with a depth of 8 ft. and a speed of 2·3 ft. per second.

Below the confluence of the Pibor and Baro the united stream, now known as the Sobat, takes a decided north-west trend, passing for some distance through a region of swamps. Just beyond the swamps and some 40 m. below the confluence, is the fortified post of Nasser. From Nasser to the junction of the Sobat with the Nile the river has a course of about 180 miles. As it approaches the Nile the Sobat flows in a well-defined channel cut in the alluvial plains through which it passes. The banks become steep, the slope rapid and the current strong. The Sobat enters the Nile almost at right angles in 9° 22′ N., 31° 31′ E. It is 400 ft. wide at its mouth and has a depth of 18 to 20 ft. at low water and of 30 ft. when in flood. The colour of the water when in moderate flood is that of milk, and it is from this circumstance that the Nile gets its name of Bahr-el-Abiad, *i.e.*, White river. In full flood the colour of the Sobat is a pale brick red. The amount of alluvium brought down is considerable. The average volume of water discharged varies from 100 cu.m. per second at low stage in

April to 770 in October and November when it is in full flood. For the part played by the Sobat in the annual rise of the Nile *see* NILE.

The Sobat was ascended for some distance in 1841 by the Egyptian expedition despatched in the previous year to explore the upper Nile. The post of Nasser was founded in 1874 by General C. G. Gordon when governor of the equatorial provinces of Egypt, and it was visited in 1876 by Dr. W. Junker, the German explorer. The exploration of the river system above Nasser was carried out in the last decade of the 19th century by the Italian explorer V. Bottego; by Colonel (then Captain) Marchand, of the French army, who, on his way from Fashoda to France, navigated the Baro up to the foot of the mountains; and by Captain M. S. Wellby, Majors H. H. Austin and R. G. T. Bright, of the British army, and others. By the agreement of May 15, 1902, between Great Britain and Abyssinia the lower courses of the Pibor and Baro rivers to their point of confluence form the frontier between the Anglo-Egyptian Sudan and Abyssinia. (*See* NILE, SUDAN and ABYSSINIA.)

SOBRAON, a decisive battle in the first Sikh War (*see* SIKH WARS). It was fought on Feb. 16, 1846, between the British (15,000) under Sir Hugh Gough and the Sikhs (20,000) under Tej Singh and Lal Singh. The Sikhs had fortified themselves in a bend on the left bank of the Sutlej, with the river in their rear. The battle began with a two hours' artillery duel, in which the Sikh guns were the more powerful, and the British heavy guns expended their ammunition. Then the infantry advanced with the bayonet, and after a fierce struggle took the Sikh entrenchments. The Sikh losses were estimated at from 5,000 to 8,000. This battle ended the first Sikh War.

SOCAGE. A free tenement held in fee simple by services of an economic kind, such as the payment of rent or the performance of some agricultural work, was termed in mediaeval English law a socage tenement. In a borough a similar holding was called a burgage tenement. The term is derived from O. Eng. *soc,* which means primarily suit, but can also signify jurisdiction and a franchise district (*see* SOKE). Historically two principal periods may be distinguished in the evolution of the tenure. At the close of the Anglo-Saxon epoch we find a group of freemen differentiated from the ordinary ceorls because of their greater independence and better personal standing. They are classified as *sokemen* in opposition to the *villani* in Domesday Book, and are chiefly to be found in the Danelaw and in East Anglia. There can hardly be a doubt that previously most of the Saxon ceorls in other parts of England enjoyed a similar condition. In consequence of the Norman Conquest and of the formation of the common law the tenure was developed into the lowest form of freehold. Legal protection in the public courts for the tenure and services deemed certain, appear as its characteristic feature in contrast to villeinage. Certainty and legal protection were so essential that even villein holdings were treated as *villein socage* when legal protection was obtainable for it, as was actually the case with the peasants on ancient demesne who could sue their lords by the little writ of right and the *Monstraverunt.* The Old English origins of the tenure are still apparent even at this time in the shape of some of its incidents, especially in the absence of feudal wardship and marriage. Minors inheriting socage come under the guardianship not of the lord but of the nearest male relative not entitled to succession. An heiress in socage was free to contract marriage without the interference of the lord. Customs of succession were also peculiar in many cases of socage tenure, and the feudal rule of primogeniture was not generally enforced. Commutation, the enfranchisement of copyholds, and the abolition of military tenures in the reign of Charles II. led to a gradual absorption of socage in the general class of freehold tenures.

SOCIAL ANTHROPOLOGY. Anthropology is the science of man and of his culture at various levels of development. It includes the study of the human frame, of racial distinctions, of civilisation, of social structure and of man's mental reactions to his environment. The problems connected with the human body, such as race, heredity, miscegenation, are the subject matter of *Physical Anthropology. Social,* called also *Cultural Anthropology,* studies questions of the culture and social organisation of primitive tribes and nations. As a rule a somewhat vague line of demarcation is drawn between peoples of simpler culture and those more highly developed, such as the modern inhabitants of Europe and N. America. The study of higher civilisations is then assigned to Sociology. The distinction, however, is unsatisfactory and it would be more correct to say that Social Anthropology is a branch of Sociology, as applied to primitive tribes. Since the study of living peoples uses methods and controls sources of information entirely different from those at the disposal of archaeology and pre-history, Social Anthropology has to restrict its scope to the study of the modern living representatives of primitive mankind.

Social Anthropology begins really with a pre-scientific interest in the strange customs and beliefs of distant and barbarous peoples, and in this form it is as old, at least, as the Father of History. Indeed traces of such pre-scientific interest can be found in the early inscriptions, paintings, reliefs and sacred writings of the Orient and even in the quaint and highly coloured stories which one primitive tribe tells of another. We have not yet succeeded in eliminating this cruder curiosity in "Ye Beastly Devices of Ye Heathen" from modern anthropology, where the thirst for the romantic, the sensational and the thrilling still plays some havoc with the sober scientific attitude.

In the establishment of this latter and of sound methods of research the lead in Great Britain was taken by General Pitt-Rivers E. B. Tylor, J. F. MacLennan and J. Lubbock (Lord Avebury); in Germany by A. Bastian and even earlier by Herder, Grimm and the *Völker-psychologists;* in France by Boucher de Perthes and Perrault.

SOCIAL ANTHROPOLOGY AS A SCIENCE

During the last quarter of the preceding century and at the beginning of this, Social Anthropology gradually crystallised into a scientific study. The specific nature of cultural process was recognised, as well as the complexity of social organisation and of primitive custom and belief. The vastness of the problem, the human interest and the dramatic beauty of anthropological facts were brought home to scholars and laymen alike by the works of W. Robertson Smith, Sir J. Frazer, E. A. Westermarck, E. Crawley and E. Sidney Hartland, to mention a few outstanding names. At the same time, scientific movements of great consequence were developing on the Continent (Durkheim and Wundt). Most important of all, the man of science began to go out into the field himself and to study native races personally by direct observation. The lead to this was given in Great Britain by the Cambridge Expedition organised by A. C. Haddon and in which such eminent anthropologists as W. H. R. Rivers and C. G. Seligman received their training in field-work. Equally fruitful were the pioneering researches of Spencer and Gillen in Australia and the activities of the Polynesian Society in New Zealand and the Pacific.

In America, where the interest in anthropology had a historical basis in both friendly and hostile contacts between settlers and redskins, modern scientific research received perhaps the first official recognition in the foundation of the Bureau of American Ethnology. Early pioneers of anthropology, J. W. Powell, J. Mooney, but above all L. H. Morgan, laid the foundations of scientific field-work and theoretical interest in the North American Indians. Later the work of Franz Boas and his school continued the scientific tradition of American social anthropology. The value of the scientific study of native races was recognised in the official patronage given to colonial research by the Dutch Government and by the German Colonial Office.

The last 20 years have been characterised by a great extension of scientific field work among primitive peoples, by further development of the theoretical work of the opening years of the century

and by important discussions of the methods and aims of anthropology.

MODERN SCHOOLS

In spite of much fuller knowledge of primitive cultures, modern theory presents great diversity.

Two dominant tendencies are recognised in modern anthropology. The one, usually described as the "evolutionary" or "comparative" or "independent origins" school, is based on the assumption that a preponderant part in the formation of human culture has been played by independent evolution taking place on the same lines in various parts of the world. Similarities in custom, institution and belief are in this school explained on the principle that human nature produces at the same level of development identical or similar forms.

The "diffusionist" school on the other hand place all the emphasis on cultural borrowing by one people from another. Similarities in implements and weapons, in beliefs and legends, in social organisation and decorative art are explained by spread from one or several original centres (*see* below).

Only a few extremists, however, belong to either school exclusively or maintain that one factor only accounts for all similarities of culture, either independent evolution or diffusion. The majority of anthropologists recognise—and are unquestionably correct in doing so—that cultural change is always a mixture of both independent development and partial borrowing from other people. In reality the main tendencies of modern Social Anthropology can be stated thus.

Psychological Interpretation of Culture.—Continuing the direct tradition of the German folk-psychologists, as well as of the British classical school, Wundt, Vierkandt, Krueger and their collaborators attempt to explain systematically the phenomena of language, custom, belief and social organisation by references to psychological processes. Quite as exclusively psychological are the contributions of the psycho-analysts, who account for totemism, taboo, initiation ceremonies, in fact for the whole field of primitive cultures, by unconscious mental mechanisms. Psychological interest is also predominant in the works of Frazer, Van Gennep, Sumner, Crawley and Westermarck. All these writers belong on the whole to the evolutionist school.

The extreme representative of the diffusionist school, Graebner, maintains that all the regularities of cultural process are "laws of mental life" and that "their scientific and methodical study is possible only from the psychological point of view" (Graebner, p. 582, 1923), while Pater Schmidt, Wissler, Lowie, Kroeber and Rivers constantly use psychological interpretations. Thus, no anthropologist nowadays wishes completely to eliminate the study of mental processes, but both those who apply psychological explanations from the outset and those who want to use them after culture has been "historically analysed" forget that interpretation of culture in terms of individual psychology is as fruitless as mere historical analysis; and that to dissociate the studies of mind, of society and of culture, is to foredoom the results.

The Distribution, Contact and Diffusion of Culture.—As influential and one-sided as the psychological trend is the interpretation of similarities and analogies of culture by the principle of mechanical transmission. First vigorously propounded by Ratzel as the main problem of ethnology, the study of distribution and diffusion has been followed up by Frobenius, Ankermann, Graebner, Pater W. Schmidt, Pater Koppers and subsequently by the late Dr. Rivers. In England Prof. Elliot Smith and W. J. Perry have carried the diffusionist argument even farther, deriving all culture the world over from Egypt.

The merit of moderate anthropological diffusionism lies in its geographical rather than in its historical contributions. As a survey of facts correlated to their geographical substratum, it is a valuable method of bringing out the influence of physical habitat as well as the possibilities of cultural transmission. The distributions mapped out for America by Boas, Spinden, Lowie, Wissler, Kroeber, Rivet and Nordenskiöld; the survey of Melanesian cultures given by Graebner; of Australian provinces given by W. Schmidt; of Africa prepared by Ankermann and Herskovits, will possess lasting value.

The historical hypotheses of Frobenius, Rivers, Schmidt and Graebner, the sweeping identifications of "culture complexes" all over the globe, will not so easily pass muster. They suffer from a lifeless and inorganic view of culture and treat it as a thing which can be preserved in cold storage for centuries, transported across oceans and continents, mechanically taken to pieces and recompounded. Historical reconstructions within limited areas, such as have been done upon American material for instance, in so far as they are based on definite records or on archaeological evidence, give results which can be empirically verified, and therefore are of scientific value. Dr. B. Laufer's study on the potter's wheel and certain contributions to the history of American culture (T. A. Joyce, A. V. Kiddler, N. C. Nelson, H. J. Spinden, L. Spier) are methodologically acceptable, though they belong to archaeology rather than to the science of living races and cultures. Such sound works must be clearly distinguished from the productions in which a conjectural history is invented *ad hoc* in order to account for actual and observable fact, in which therefore the known and empirical is "explained" by the imaginary and unknowable.

Sociological Theories of Culture.—Robertson Smith is undoubtedly the spiritual father of this movement. He was the first to see that religion must be accounted for quite as much by its social nature, by what it does for tribal cohesion, as by its meaning and value for the individual. The great American Anthropologists, Powell and Morgan, also contributed toward our understanding of clan solidarity in savage societies. Durkheim, inspired by their work as well as by that of Bachofen, Wilken and Sir James Frazer, developed a sociological theory of early culture. Kohler and the school of comparative jurisprudence in Germany, Steinmetz in Holland and later, Rivers in England, also studied primitive society from the sociological point of view, overemphasising perhaps the solidarity of and the lack of differentiation within the early horde and clan. The doctrine of primitive legal cohesion and of social structure by direct solidarity given by Durkheim, Steinmetz and Kohler; the subtle and stimulating interpretation of primitive magic, sacrifice and religion by Durkheim, Hubert and Mauss; the recent analysis of contract and gift by Mauss and Davy, show an enormous advance upon any previous work in the greater precision of concepts, in the consistent application of the sociological interpretation, in the conscious attempt to preserve native classification, nomenclature and perspective. It is impossible to adopt these views unreservedly because they tend to lapse into metaphysical vagueness. In order to avoid the explanation of culture in terms of individual mental processes, yet fully aware that psychology cannot be excluded, these anthropologists compromise by introducing the conception of collective consciousness, which sociologists and anthropologists alike (Ginsberg, MacIver, Radin) have shown to be untenable. The sociological school exaggerates the social nature of primitive man, the importance of the clan and the solidarity of kinship. They neglect the role of individual initiative and variation, the part played by self-interest and the institution of the individual family.

Theories of Specific Difference of Primitive Mentality.—Grown on the soil of the sociological school, but laying more stress on the purely psychological side, other theories seek to account for savage belief and custom by the alleged specific character of mental structure in primitive man. Basing their conclusions on a number of interesting but probably exaggerated and distorted statements by such observers as Cushing and Dennett, and on a mass of obviously immature and superficial accounts by missionaries and other amateurs, the writers of this school aver that the savage is prelogical and mystical, impervious to experience, living in a world of "dim participations" (Crawley, Lévy-Bruhl, Vierkandt, Danzel, H. Werner, Graebner). These views have but limited currency among theoretical anthropologists, whose position has been well expounded by Carveth Read. Modern field-workers, equally competent to speak about the savage from first-hand knowledge and to deal with problems of comparative psychology and epistemology through training, have one and all criticised adversely these points of view (Boas, Rivers, Radin, Kroeber).

None the less, by posing the problem of primitive knowledge and mentality, by stirring up opinion and forcing anthropologists to make up their minds, the writers of this school, above all M. Lévy-Bruhl, have made valuable contribution to Science.

The Functional Analysis of Culture.—This type of theory aims at the explanation of anthropological facts at all levels of development by their function, by the part which they play within the integral system of culture, by the manner in which they are related to each other within the system, and by the way in which this system is related to the physical surroundings. It aims at the understanding of the nature of culture, rather than at conjectural reconstructions of its evolution or of past historical events.

Two factors contribute toward the development of the functional point of view. The modern specialist field-worker soon recognises that in order to *see* the facts of savage life, it is necessary to understand the nature of the cultural process. Description cannot be separated from explanation, since in the words of a great physicist, "explanation is nothing but condensed description." Every observer should ruthlessly banish from his work conjecture, preconceived assumptions and hypothetical schemes, but not theory.

The field-worker who lives among savages soon discards the antiquarian outlook. He sees every implement constantly used; every custom backed up by strong feeling and cogent ideas; every detail of social organisation active and effective. He perceives, above all, that culture, provides primitive man with the means of satisfying his wants, and of mastering his surroundings. The functional view of culture lays down the principle that in every type of civilisation, every custom, material object, idea and belief fulfils some vital function, has some task to accomplish, represents an indispensable part within a working whole.

The better a custom is understood, the clearer it becomes that it does not sit loosely, within its context, that it is not a simply detachable unit like a petrifact in a rock, but that it is organically connected with the rest of the culture. A "superstition" is always a powerful mental force, whether as a restraint, or as an incentive to action. Magic, again, in many of its forms, is an indispensable economic force. Sorcery plays a conspicuous part in the political organisation and the legal arrangements of most tribes. Religion, through the moral integration of the group, invariably provides the basis of a tribal constitution. This mutual relation of customs, aspects and institutions; the work which they do for each other; the function which they fulfil within the whole scheme of culture—this it is that interests the exponent of the functional method.

This method insists, therefore, not only on the dynamic nature of culture, but also upon its organic unity. Culture must not be treated as a loose agglomeration of customs, as a heap of anthropological curiosities, but as a connected living whole. The functional method protests against the tearing away of a custom, institution or aspect from its cultural context. "Magic," "cannibalism," "sociology," "religion," "pottery," "mother-in-law taboos," "marriage," and many other such labels, have given rise to the water-tight compartment method of collecting evidence in the field, of writing it up, and of dealing with anthropological theory.

The functional view of anthropology refuses to regard cultural process as a mere natural growth—through the biological simile of evolution. It refuses also to see in it a simple shifting of disconnected items from place to place—through the mechanical simile of diffusion. The functional method insists on the recognition of the process of culture as a process *sui generis,* which must be studied by special methods, without borrowing from physics, biology or the limbo of untrammelled conjecture; culture is alive, it is dynamic, all its elements are interconnected, and each fulfils a specific function in the integral scheme. The discovery of cultural functions makes it possible for this method to lay down the laws of the functional correlations of anthropology.

Modern field-work thus regards a theory as purely empirical, never to be taken beyond the limits of induction set by the evidence, and as serving only to give a greater insight into the mechanism of culture in its various phases; social organisation, belief and material outfit.

The functional view of culture is implicit in the work of many of the leading writers of the comparative school and in the best achievements of modern field-work. The Comparative school however has allowed the evolutionary view to overshadow the functional method, while most American anthropologists have failed to disentangle the empirical interpretation of culture in terms of function from reconstruction in terms of conjectural history. They have thus lapsed into a type of explanation which at best belongs to archaeology, and so have greatly sterilised their otherwise splendid field-work and stimulating theory.

Recently, however, and among a small number of anthropologists only, the functional method has been applied systematically and exclusively in field-work and theory (R. W. Firth; B. Malinowski; G. Pitt-Rivers; A. Radcliffe-Brown; Richard Thurnwald).

The functional method by showing what culture does for a primitive community, establishes its value and thus utters a warning against too hasty interference with native belief and institutions and too wasteful an exploitation of native labour and resources. By demonstrating how primitive custom and law work, it furnishes the administrator with practical hints of how to frame and administer native regulations. By inquiring into savage economic organisation, the functional method can teach how to manage indigenous labour and how to trade with the natives. By a sympathetic study of early belief and ritual, it can instruct the missionary how to graft a new creed upon the old one without destroying what is good and sound in it.

The functional method, concerned as it is with the actual working and mechanism of primitive culture, supplies the right theoretical foundation for the practical application of anthropology (*see* ANTHROPOLOGY, APPLIED), for which mere antiquarian reconstructions, whether historical or evolutionary, are irrelevant. And indeed recently the future of relations between Europeans and native peoples has come to be recognised as one of the momentous problems of our times. A number of important movements and works indicate the recognition of the necessity for a closer co-operation between the Anthropologist and the man who controls tropical colonies. From the official side there may be quoted Lord Lugard's policy of *indirect* or *dependent* rule, so brilliantly vindicated in his own administration and so well expounded in his book on *The Dual Mandate in British Tropical Africa;* the recent appointment of several Government Anthropologists in British Colonies; and the charter of the Mandated Territories. From the missionary point of view may be mentioned J. H. Oldham's excellent book *Christianity and the Race Problem,* while as a scientific approach to practical Anthropology, *The Clash of Culture and the Contact of Races* by G. Pitt-Rivers is a pioneering piece of work.

The following analysis of some of the main aspects of primitive organisation will best illustrate the subject matter, the aims and the methods of Social Anthropology.

THE CULTURAL FUNCTION OF MARRIAGE AND FAMILY

This is perhaps the most debated and the most instructive of all anthropological problems.

The Institutions of Marriage and Family.—Careful inductive comparison reveals one important fact: marriage and family are almost universal, and can be traced through all types and levels of culture. Their universality can be accounted for by the functional analysis of these institutions. Two functions of paramount importance are fulfilled by any institution which regulates mating and propagation: the maintenance of racial quality and the maintenance of the continuity of culture. Sociological considerations prove that the individual family based on monogamous marriage provides the best opportunities for effective sexual selection. It also supplies the best training for the future cultural work and sociological orientation of the young individual. The importance of the family as the early social and cultural pattern for later life has been independently established

by anthropology and psycho-analysis. The family is the link between instinctive endowment and the acquisition of cultural inheritance, in that it permits the biological bonds between parent and infant gradually to ripen into social ties. It also eliminates a number of dangers due to the disruptive factors of the sexual instinct. (A. L. Kroeber; J. C. Flügel; R. H. Lowie; A. R. Radcliffe-Brown; B. Malinowski.)

Regulated Licence.—The various customs of regulated licence do not allow of a simple and satisfactory solution. As culture advances and larger numbers of men and women come into contact, the experimental component of the sexual instinct drives people towards indiscriminate mating. Freedom in pre-nuptial intercourse, festive licence, religious prostitution, lewd marriage ceremonies are the rule in savage and barbarous communities, with the exception of those of the lowest level (Schmidt and Koppers). Again, in some tribes the institution of marriage suffers temporary obliteration in the form of wife-lending or exchange, *jus primae noctis* sexual over-rights of chiefs and magicians and similar relaxations of the matrimonial bond. These customs have been explained as "survivals of primitive promiscuity." That such an explanation is untenable has been convincingly shown by Westermarck. There are two ways of regulating intercourse between the sexes: either by suppressing all irregular mating, or by allowing a well-defined and limited licence. Biology and psycho-analytic theory teach that stern repression and rigid sex morals are not a complete solution of the problems here involved. Anthropology, moreover, shows that this problem is especially present at low levels of culture. According to some authorities, a regulated and limited licence should be considered as an imperfect but effective way of dealing with the disruptive forces of sex. Such regulation, moreover, is in no savage tribe found to be subversive to the fundamental institutions of marriage and the family which exist in spite of it everywhere.

At the same time, there is not one single tribe where sexual licence is found untrammelled, where anything approaching promiscuity obtains. Two forms of regulation are found everywhere: the strict prohibition of the wife's adultery safeguards the bonds of marriage and is only now and then over-ruled by exceptional customs; the prohibition of incest within the household safeguards the integrity of the family. This is very often extended to exogamy which embraces the whole clan.

The Clan (*q.v.*).—The clan and the classificatory principle of kinship appear on a closer sociological analysis not to be substitutes for the family and household, but the outcome of more extended co-operation in matters other than sexual mating and the rearing of children. (*See* KINSHIP.) The clan functions chiefly in economic, legal and above all in ceremonial matters. It is also closely connected with age-grades, secret societies and men's clubs wherever these exist; with the ceremonial distribution of wealth (the *kula*, the *potlach* or the *hakari*), with magical specialisation and co-operation. Thus, in its functional definition, the clan represents the non-sexual and non-genetic extension of the kinship principle beyond the household and above the natural function of the family. Exogamy again appears as an additional bond of solidarity—a natural extension of the principle of incest running side by side with the extension of the kinship principle. As the link between the individual and the wider groupings of local and political type, the clan is of special importance.

The clan is always due to the over-emphasis of one side of kinship—an over-emphasis necessary to eliminate any ambiguity in the transmission of hereditary rights and obligations. This has been aptly summed up by Dr. Lowie in his terminology of bilateral and unilateral kinship. The clan appears therefore as the natural result of the two influences which come into the foreground as culture advances; the continuity of tradition on the one hand and the extension of co-operation on the other. The clan allows of the establishment of greater cohesion within each generation and across succeeding generations. The explanation here given accounts for the institution, neither by an accident, nor by specific ideas, nor by a hypothetical primitive communism in sexual matters, but by reference to certain deep-seated influences of cultural progress working before our very eyes. With all this, although the clan is of great benefit for society and culture, it never becomes an absolute necessity like the family. It is rather a symptom of advancing social differentiation than its inevitable effect. Thus, although the family and marriage are found to be universal, there exist tribes without any sub-divisions into clans, moieties or matrimonial classes. Further, since the clan is associated with the general scheme of development, it cannot be regarded as a fortuitous index of this or that culture.

Mother-right and Father-right (*q.v.*).—The correlated phenomenon of unilateral kinship also plays a very important part in diffusionist schemes. Mother-right and father-right respectively have been taken by Ankermann, Graebner, Rivers, W. Schmidt and Koppers as principal indices in their classification of cultures. But the question arises, is either mother-right or father-right an independent element, or are they both always linked together? It seems in fact that mother-right and father-right are never found in isolation, but always co-exist—one of them emphasised by the tribal law and the economic arrangements, the other, though subordinate, never completely absent. Until the problem thus raised has been solved, until the proof is given that mother-right and father-right can exist as exclusive, sharply defined stages or sociological principles, their use as indices of culture, and evidence of its spread must remain meaningless. Here again, functional analysis of the methods of reckoning descent leads to a clear definition of such concepts, indispensable for their use in any speculative construction. (*Cf.* B. Malinowski, *Sex and Repression*, Pt. iv.)

Problem of Sex.—Thus the family, the clan, sexual restrictions, as well as sexual liberties, are not the stages of a transformation nor fortuitous indices of cultural type or cultural stratum, but correlated, component parts of one big institution; the institution which controls the mating of sexes, the procreation of offspring and the education of the young, and fulfils the integral function of racial and cultural continuity. The nature of its component elements is explained by the part which they play within this integral scheme. The functional method might also be extended to all the other aspects of organisation—territorial, political, legal and economic. Each is related to an essential need of human society, its distribution over the locality, defence, maintenance of order, and the production of necessaries and values.

ECONOMIC ORGANISATION

Until the recent researches of anthropologists in Melanesia, in New Zealand, in North-West America, in Africa, and in Micronesia revealed a wealth of material, and theoretical students (M. Weber, K. Buecher, R. Thurnwald, R. W. Firth, B. Malinowski) laid stress on the cultural importance of primitive economics, there reigned in anthropology the simple occupational view of primitive husbandry. Schemes of occupational stages or types, the collecting of food, hunting, fishing, the tending of herds, the raising of crops and industrial production were set forward as the only subject matter of descriptive or analytical economics, as it is called.

In all such views, primitive man is regarded as having but simple elementary needs, and proceeding reasonably and naturally to satisfy them. The little spare time he has left over he devotes to the casual production of superfluities, and to the satisfaction of his hobbies, which latter activities, however, are usually placed outside the domain of economics. Thus we read in an authoritative work, *Notes and Queries in Anthropology* (Edn. 1912, p. 260) "The first essential of maintenance is a supply of food; and in many simple communities the actual food quest and operations arising from it . . . occupy by far the greater part of the people's time and energy, leaving little opportunity for the satisfaction of any lesser needs." And again, we are told by another writer (Buxton) that generally the savage "has no means to acquire more wealth than he can carry about on his person or on the persons of his family." The main questions cut short by such *a priori* assumptions are those of the incentives to production, of the organisation of labour and of the primitive forms of the apportionment of wealth.

The Economic Motive.—Is it true then that primitives work only to satisfy their primary needs? In the lowest stages of culture people are ready to endure thirst and hunger, but are bent upon stimulants or narcotics. We know of tribes without clothing, but of none without ornaments. There are natives without fixed habitations yet keen on the display of such wealth as they possess. At higher levels, under more favourable conditions, certain commodities are actually produced far in excess of actual needs. And this, moreover, is not done "in exchange for food or for the means of obtaining it," as current opinion usually runs (*Notes and Queries*).

Nor is it carried out through economic foresight. Large quantities of accumulated food and wealth are employed instead for festive display, for ceremonial yet useless donations, sometimes even for mere destruction, often on a gigantic scale. All such customs serve merely for the manifestation of the wealth of the owner, of his generosity, of his economic power. In the South Seas, the accumulated food is employed for the production of objects of value by the feeding of artisans, who devote themselves to the polishing of axe-blades, to carving, to the making of shell ornaments or of mats (Thurnwald, R. W. Firth). Some of these early forms of valuable tokens of wealth have a distinctly religious character, serve in ritual ceremonies, are associated with belief and possess elaborate mythical pedigrees (Mauss). Finally there is one very important fact which contradicts the merely utilitarian view of primitive economic incentives; the products of savage industries in general, far from being made with the minimum of effort required for their utility, show a lavishness of artistic detail, of decoration and pedantic finish, which would put to shame any civilised artisan. The joy in the work, the satisfaction of perfect craftsmanship, the artistic passion for the general appearance of the finished product dominate savage industry and enterprise (B. Malinowski).

It is clear from this evidence that the "first essentials of maintenance," the primary needs and the requirements of practical utility, do not exclusively control the economic effort of primitive man. Nor is their aim always to achieve the utilitarian maximum of effect by the minimum of effort. To understand the driving forces of early production, it is, therefore, not sufficient to make reference to man's animal needs. It is just as necessary to realise the natives' ideas of value; their pleasure in the integral effect of their work in which artistic, sporting, social and even religious motives are mixed with those of pure utility.

The Character of Early Production.—The well-known scheme of K. Buecher, who would place the whole range of primitive husbandry within the limits of the "Individual search for food" and of "closed household economy" is the clearest expression of the view that primitive man works for himself and his family alone, and that he knows no production on a wider, a communal or tribal scale.

A fuller insight into the nature of primitive labour reveals the existence of organisation. Even in the lowest cultures there are tasks which transcend the forces of one individual or of one family—the felling of trees, drive-hunting, the very collecting of food. At higher stages, such pursuits as communal hunting and fishing, the making of gardens, the construction of houses and canoes require some type of organised labour. This points to a definite specialisation, distribution and synchronisation in time, a division of functions, an integration of the individual contributions to the common end. If we enquire what are the elements of the economic organisation, it soon becomes clear that we must distinguish between moral or persuasive, and social or coercive factors. K. Buecher in a later work (*Arbeit und Rhythmus*) has drawn attention to the great importance of rhythm for successful work. Many other stimulants and incentives could be mentioned, the most efficient of which is unquestionably work in company. Conversation, jokes, mutual assistance and interest relieve the tedium of solitary labour, while emulation, example and the satisfaction of pride are under primitive conditions possible only in communal work. The best worker is always recognised as such among savages, and his leadership is followed. Much more important, however, is the moral prestige enjoyed by supernatural expert knowledge which, in the form of magic, always controls vital and difficult economic pursuits. Marking the dates, inaugurating the successive stages, imposing periods of rest and setting the time limits, it acts as an organising, co-ordinating influence (B. Malinowski in *Argonauts of the Western Pacific*).

Social coercion is the other important force in economic organisation. As soon as distinctions of rank and power arise they are used as means of extorting labour, while, on the other hand, economic inequalities function as indices of social status.

Primitive Ownership.—This economic problem has been discussed in some detail by anthropologists. But while, on the one hand, the writers, who, like Buecher, assume an atomised economic production, admit only of individual or personal ownership, those following Morgan, and influenced by a strong socialistic bent, Engels, Bebel, Cunow, make the savage into a communist. As a matter of fact, property, which is but one form of legal relationship, is neither purely individualistic nor communal, but always mixed (B. Malinowski, *Crime and Custom*).

The misuse of such conceptions as "communism," associated with an incorrect application of the concept of "money" may be exemplified in a scheme recently put forward by the late Dr. Rivers. Dr. Rivers designates certain forms of valuables found in Melanesia, such as mats, arrows, pigs' jawbones and, above all, shell discs, as "money," following the usage of white traders, missionaries and planters. Dr. Rivers to justify the use of this word, insists that these objects "are used for no other purpose" and "have a very definite scale of value," but he gives in other contexts a definite and concrete account of several ways in which these objects are used "for other purposes," and thus stultifies his first criterion. The second criterion is obviously insufficient for identifying a commodity as "money." All objects have in our economy "a very definite scale of value," yet we do not apply the word money to a pair of slippers, a motor-car or a picture by Raphael, still less do we use these things as money.

Now the taking of terminological liberties with well-defined concepts has its dangers. "Money" has no sooner been introduced into the argument than "communism" crops up and the two are related by a remarkable piece of reasoning.

"The subject of communism in property is closely connected with that of money. A thoroughly communistic people can have no use for money among themselves. If they possess anything which can be regarded as currency it can only be used in transactions with other peoples. The use of money should therefore be associated with the disappearance of communism; if it can be shown that Melanesian money is due to immigrant influence, and especially to that of the Kava people, we shall have gone far to establish the conclusions already suggested" (*History of Melanesian Society*, vol. 2, p. 385).

And again:

"A thoroughly communistic people would have no need for money, and any explanation of the communism of Polynesia will therefore furnish also the explanation of the absence of money" (p. 392).

And as an "historical explanation" of these facts:

"The explanation of the absence of money in Polynesia and of the communism of its people is to be found in the special mode of settlement of the Kava people" (p. 393).

What a "thoroughly communistic people" are is difficult to say. The Bolshevik regime aspires to that title, but they have not done away with money, they use it in fact for internal purposes without qualms or difficulties. On the other hand, the Central Australians, the Fuegians and the Melanesians of Eastern New Guinea have a keen sense of individual property, yet they use no money or currency. The fact is that neither in primitive nor in advanced cultures is there any correlation between communism and absence of money. Under a system of rigid individual property, exchange takes place in the form of direct barter; in a highly developed economic organisation with money and banking systems, the community may control almost completely the resources of the individual and establish thorough-going communism.

It can be very seriously doubted whether Dr. Rivers has ever

proved that in some parts of the Western Pacific there exists communism and in others individualism, nor as we have seen is his statement that certain objects are money functionally correct. The absence of money on the other hand which Dr. Rivers explains by the existence of communism can be very simply accounted for by the absence of any need for it under primitive conditions. The moral of this criticism is that we need in Anthropology far greater precision in the use of terms and the definition of concepts and far richer and minuter observations on economic matters. We can dispense on the other hand with daring speculations about absence of property or presence of monetary systems in pre-historic Oceania.

Summary.—To sum up briefly, it is incorrect to assume that man for a long time has lived in a semi-natural primitive stage of individual acquisition of food and primary utilities. Equally untrue is the correlated assumption that he lifted himself out of this condition by the gradual application of the economic principle of maximum of effect for the minimum of effort. Instead, from the outset, artificial, cultural, non-instinctive aims have been indispensable to him and his culture. Early types of value and symbols of wealth have spurred him from the outset to economic effort. This effort is organised and standardised by tradition. The real problem, therefore, consists in gaining insight into the primitive forms of condensed wealth, into the mixture of motives and impulses which drive man and in studying the manner in which these primitive incentives control organised effective effort. All the conclusions arrived at show that for the discussion of economic problems it is necessary to consider the relations of early wealth to religion and to magic as well as its function in primitive social structure.

The borderland questions—the influence of economics on social structure; the problem of wealth as the foundation of rank, power and status; the rule of give-and-take in social obligations; ceremonial distribution of goods, and its economic importance—are gradually coming into the forefront of anthropological interest, and open up entirely new horizons in theory and field-work. They bring it into close contact with the disciplines of economics, history and sociology (Buecher, Schwiedland, M. Weber, K. Lamprecht).

The relation between the various larger aspects of culture opens a new type of problem. Social organisation is largely dependent upon economic foundations, while economics cannot be studied without a knowledge of the various groups within the tribe. Religion and magic are not independent, but are intimately associated with economic pursuits, with power and prestige, with domestic life and everyday necessities.

THE SUPERNATURAL

Here the functional view is put to its acid test. What can be the function of primitive belief and superstition, of animism considered as valueless, crude and mistaken, of magic, regarded as spurious and fallacious pseudo-science, of totemism, of barbarous burial ceremonies and of cruel initiation rites? Yet the method here set forth stands or falls with the possibility of defining the whole of the supernatural. It is bound to show in what way belief and ritual work for social integration, technical and economic efficiency, for culture as a whole—indirectly therefore for the biological and social welfare of each individual member.

The great majority of modern theories in fact come near to the posing of this problem and to its solution. It is implied in the whole structure of Frazer's *Golden Bough*, in the contributions of Westermarck to the moral side of religion, in Durkheim's analysis of the integrative function of public ceremonial, in the additions of Hubert and Mauss to his theories, in Marett's analysis of magic, in Crawley's vitalistic view of religion, above all, in the analysis of Andaman belief and ceremonial by A. Radcliffe-Brown. But too often the functional view is still smothered by evolutionary or historical discussions—as to whether magic preceded religion, as to what was the primitive form of religion, and so on.

Magic (*q.v.*).—The majority of theories dealing with magic range between two views that are apparently opposed, which label magic as primitive science or primitive stupidity (*Urdummheit*) respectively. We must reject the implication of the first theory, that magic preceded science, and that once it fulfilled that function. It must be placed to the credit of this theory, however, that it does full justice to the practical context of magic. The second theory emphasising the central conception of impersonal ubiquitous force—*mana, orenda, wakan*—rightly appreciates the difference between belief and knowledge; and brings out the mystical character of magic (Marett, Hubert and Mauss, Preuss).

The functional theory reconciles the two points of view. Let us start from the close association of magic with practical activities. First, every practical pursuit amongst savages is always primarily based upon knowledge and is never exclusively controlled by magic. There are in all savage cultures certain activities in which technical ability, guided by knowledge, completely suffices. In others, the help of magic is also invoked. What are the respective contributions of knowledge and of magic to such a mixed activity? In its essentials the division of function between the two is very simple; as far as his knowledge goes, as far as he can safely rely on experience, reason and technical ability, the native—whether in his gardening or fishing, the building of craft, in warfare or sailing—does not use magic. No savage has ever been observed to select the tree for his dug-out by divination, to bring forth seedings by formulae without having planted them. Only where, in spite of knowledge and effort, the results still turn unaccountably against him, only when forces completely beyond his mental grasp and practical control baffle him—in dealing with garden pests, with the supply of fish and animals, in securing favourable wind or weather, in preventing disaster at sea or in war, above all in dealing with bodily decay, disease or personal accidents—does the savage resort to supernatural means of filling the lacunae in his practical power.

The type of belief met in magic is always an affirmation of man's power to deal with the situation by a rite or spell. This belief simply repeats in a standardised manner, what hope all the time has whispered within the individual's own mind. Again, the rite repeats in a fixed, definite form what the natural expression of emotions already contains, only, as a rite, it is carried out with a purpose and with the conviction that it is a means to an end.

When we compare the forms of the fixed magical ritual, they are remarkably akin to the response of disturbed equilibrium occurring under similar conditions. Black magic, which corresponds to the sentiment of hate, and which replaces the outbursts of impotent rage, contains in its most typical ritual of stabbing, pointing the bone, mimic destruction, and in the text of its formulae, a reproduction of the various gestures, words and types of behaviour, which we can watch in the natural vent of the emotions. Exorcism of evil powers repeats in word and deed the reactions of fear.

In all practical activities, the goal is brought vividly before the mental vision at moments of uncertainty and suspense—a state of mind which we call "hope." Now magical ritual, which bridges over the fateful moments, invariably expresses the suggestions of hope and baffled desire. Sir J. Frazer's apposite term of "imitative magic" and his exhaustive illustrations of his point of view are another way of stating the present theory. Here it is only suggested that the association of "ideas," designated by Frazer as the cause of "imitative magic," can only be accounted for by our theory of imperfect biological adjustment induced by culture. Baffled instinct arouses emotional tension as well as a conflict of ideas and an impasse in conduct. Through magic, culture prescribes the adequate ideas, standardises the valuable emotional tone and establishes a line of conduct which carries man over the dangerous moment.

This new type of explanation, based on the functional method, shows how cultural behaviour, in the very act of bestowing immense benefits and advantages on man, also opens up new problems and creates new needs. To satisfy these a new type of behaviour, ritual practices, and a new mental adjustment, faith or mystical outlook, come into being, thus providing an answer to the question which is always essential: What actual benefit does magic confer upon man, what is its positive contribution to culture? It is a remedy for specific maladjustments and mental

conflicts, which culture creates in allowing man to transcend his biological equipment.

Social Consequences.—In its traditional aspect, magic leads to important social consequences. It is the essence of magical lore that every word of a formula must be spoken correctly, without omission or alteration, every detail of the rite performed. Since magical knowledge can live only in man's memory, the correct transmission, the legitimate filiation of magic are essential to man's confidence in its efficiency. The inheritance of magic is always one of the most important problems of descent and of the modes of reckoning kinship. As a rule, magic is handed on within the family circle.

In this connection it is important to stress that *all* forms of magic usually perform an important social role. No magic can be regarded as anti-social in the sense in which Durkheim and his school attempt to define it. Even sorcery or black magic functions as a legitimate though dangerous weapon, of which one of the main uses is the enforcing of an established power and the biddings of law. The actual manner in which magic is connected with practical activities makes it, as we have seen, the very skeleton of economic organisation. It supplies most of the co-ordinating and driving forces of labour, it develops the qualities of forethought, of order, of steadiness and punctuality, which are essential to all successful enterprise. Thus magic fulfils an indispensable function within culture. It satisfies a definite need which cannot be satisfied by any other factor of primitive civilisation.

Totemism.—Totemism (*q.v.*) is a belief which affirms an intimate bond between a group of men and an animal or vegetable species, or sometimes a class of objects. It raises therefore two problems, the first as to the nature of the belief, the second as to the social organisation with which it is linked.

Most theories have seen its origin in some small or accidental detail of social organisation or belief, as in nicknames, guardian spirits, transmigration of souls and, recently, in the Freudian theory of parricide. To the functional theory the real problem, however, is: what is the function of a type of belief which affirms the affinity between man and animal, is correlated with clan organisation, and leads to moral and ritual rules associated with the multiplication, killing and eating of animals?

Man's interest in his surroundings is primarily practical. He has to collect food, construct his dwelling and roam about his district to hunt or fish. In the forefront of importance are the animals in his territory—those which feed him, those whose skins clothe him, whose feathers, teeth and claws supply him with ornaments and those which threaten his safety or comfort. Hence all animal life has an intense interest and significance for him.

Now in dealing with the animal kingdom, in obtaining the useful and defending himself against the dangerous or repulsive species, primitive man, where his natural means fail him has recourse to the supernatural. The magical claims over any aspect of nature lead always to an assertion of a sort of affinity or kinship between the magician and the object controlled. Indeed most magic implies mythological descent from animals or affiliation to them. Thus we see that the native's practical interest in the animal or vegetable kingdom leads through magic directly to the assertion of a mutual bond.

Magic has a tendency to become specialised and departmental, exclusive and hereditary in a kinship group or clan. The subdivision of the tribe into totemic clans seems to be best explained therefore, by the hypothesis that such clans were originally magical bodies engaged in controlling, through spell and rite, certain animal or vegetable species for the welfare of the tribe.

Thus is assigned to totemism a definite cultural function. Selective interest in vitally relevant factors of the environment, man's capacity to control it, are embodied in a system of beliefs which standardise, enhance and sacralise these culturally valuable mental states. By endorsing man's confidence and his hopes of effective control, by making these tendencies substantial in an explicit mythological dogma, totemism contributes to individual happiness, to social cohesion and to the general efficiency of culture.

In recent work (Frazer, Crawley, Van Gennep, Miss Jane Harrison) much stress has been laid upon the association of religion with the crises of life. In fact in most religions, savage or civilised, the main phases of human life history—conception and pregnancy, birth and puberty, marriage and death—are associated with belief, ritual and mythological stories. Religion therefore fulfils at vital crises an indispensable function in the scheme of human culture.

Culture entails a transformation of direct instinctive response into a mode of behaviour governed by purposive ends, that is, by cultural values. But here in the very act of bestowing her blessings, culture heaps up burdens and creates difficulties. The fruit of knowledge is a dangerous thing, and in giving man forethought, culture gives him also the terrors and pangs of despondency; it makes him probe into his own destiny, and ponder over the ultimate things of human existence. Belief in immortality, early ideas of spirits, gods and beneficent powers, give man comfort and dispel his early misgivings. The role of religion consists in the establishment of spiritual ends, dogmatic realities and moral rules of conduct. In totemism, which sacralises important factors of the environment; in the belief in immortality and in the associated ideas about communion with spirits and their influence on human fate; in the consecration of food and of indispensable elements of culture, such as fire, standard implements, tokens of wealth; in surrounding tribal tradition and order with the halo of sanctity, religion is the source of social and cultural values. Again since man is to adventure in pursuits for which he is not equipped instinctively—to move through water, jungle and desert, to invade and conquer cold, arid and tropical places—culture has to provide him with a mental force to carry him across the gaps in instinctive endowment. The necessary confidence in his own powers of controlling his environment by spell and rite are given to man in magic.

PRIMITIVE KNOWLEDGE

Reason, the capacity to know, to invent and to evolve theories, has been regarded as the distinctive mark of man, dividing Homo sapiens from other living beings. Perhaps over-confident exaggeration of this has led to the recent reaction which denies to the primitive mind any power of reasoning and of observation.

But had primitive technique been studied not as a self-contained object, but in its functional dependence upon knowledge on the one hand and magic on the other, the theory of a primitive mystical and prelogical mentality could never have been erected. Primitive man shows a rational behaviour, an unimpeachable logic and a definite power of empirical observation, not only in his technology, but also in his major economic pursuits and in his sociological behaviour.

Language.—This subject has been so far but imperfectly studied by anthropologists, and its cultural theory is as yet hardly outlined. The study of dead languages by grammarians and philologists has caused speech to be regarded as a self-contained phenomenon governed by special laws of its own. It was a considerable step forward when, some time ago, the study of language was taken up by psychologists, who began to treat it in correlation with thought and other phenomena (Lazarus, Steinthal, Wundt). The structural features of language were explained as an adequate expression of reasoning, of emotional states, of aesthetic needs and of the characteristics of the human will. Even this, however, is not sufficient.

Recent developments in linguistics, as well as in the philosophy of language, have set forth the view that language cannot at any stage of development be regarded as an adequate expression of logical, metaphysical, aesthetic or scientific categories (J. Dewey, Jespersen, Ogden and Richards). Language, in all societies and at all stages of development, is an essential part of human action (Dewey). Communication by spoken word is indispensable for any concerted activity and enters into all aspects of culture as a working element. (*See* LANGUAGE.)

From the functional point of view, a word which designates an implement is as much an essential manner of using that implement as is any type of bodily skill required to handle it. The master of a craft, however primitive, must be able to give his

orders in case of emergency in a technically adequate and theoretically correct manner, and the bodily reactions of his vocal apparatus are as essential to the practical issue as the manual dexterity of his crew. Language plays a similar part in warfare, in economic pursuits, in ceremonial activities. In religious and magical ritual, the spoken word is conceived and felt by man to be a creative act which produces a definite practical effect.

But if speech, in its primitive forms, is an indispensable instrument of cultural behaviour, its structure must be correlated to pragmatic needs and to the requirements of action rather than to logical, reflective or oratorical necessities. Hence the categories of primitive speech must be a compromise between rational and logical conditions, sociological and practical needs, and certain limitations imposed by material culture.

The problem of meaning cannot be treated by the study of language, torn out of its cultural context. The classical philologist has already summoned the archaeologist to his assistance. The study of living languages of the primitive type, helped out by the study of living cultures, would, no doubt, reveal to us infinitely more than can be reached by the study of dead speech. A word is as sterile without the knowledge of how it is used in live context, as behaviour remains mysterious without its accompanying flow of speech. Life is neither verbiage nor a pantomime. Speech has been given man for action, and as mere loquacity it is a disease of culture. (*See* PHILOLOGY.)

Mythology as Primitive Science. (*See* MYTHOLOGY.)—In order to vindicate the autonomy of knowledge within primitive culture, it is still necessary to deal with the view that, at low levels of culture, myth is a substitute for science. We read in the authoritative handbook already mentioned:—

Myths are stories which, however marvellous and improbable to us, are nevertheless related in all good faith, because they are intended or believed by the teller, to explain by means of something concrete and intelligible, an abstract idea, or such vague and difficult conceptions as creation, death, distinctions of race or animal species, the different occupations of men and women; the origins of rites and customs, or striking natural objects or prehistoric monuments; the meaning of the names of persons and places. Such stories are sometimes described as *aetiological,* because their purpose is to explain why something exists or happens (*Notes and Queries,* pp. 210 and 211).

We are thus told that primitive man evolves stories and believes in them, in order to explain abstract ideas. As a matter of fact myth is not a form of primitive science, but an aspect of religion, magic and morality; its function is not to explain queries nor to illuminate abstract or obscure points, but to strengthen belief, to substantiate morals and to enhance tradition, in short to bring home to primitive man all that has to be believed, obeyed and accepted (B. Malinowski, *Myth*).

To establish our point, we have to place myth within the scheme of primitive culture and to show its pragmatic function. Myth is a part of folklore in the narrower sense of the word, that is of oral tradition. Man in all ages and all climes possesses a body of concrete stories which can be readily divided into several classes.

Of these, the first serves predominantly for amusement and recreation. Stories of this class describe more or less dramatic or funny adventures of men and animals, ogres and hobgoblins, none of which are regarded as real. Such tales, when studied within their cultural context and regarded from the native point of view are found to play an important part in native life, in that they enhance sociability, fill out seasons of enforced idleness or make up the substance of amicable gatherings.

Another class of stories, taken more seriously, refer to important exploits and heroic deeds of past generations and are considered to be true. The sociological function of such stories is that they develop family pride, knit kinship bonds more firmly and serve to increase communal or tribal solidarity.

There are finally stories which are regarded as sacred and connected in a specific manner with magical and religious cult, with social organisation and with the body of tribal custom and moral rules. These and these only could be regarded as "explanatory" stories, in that among other subjects, they account for the origin of the world, give the reasons for death, furnish revelations of future existence, and promise immortality, narrate the beginnings of magic, and so on. The explanatory character, however, is prominent only as long as the story is considered without its cultural context. In all cases where the associated ideas and feelings have been observed; where we know the conditions under which the myth is recited or enacted; above all where the practical influence of the myth has been studied—we are able to assign a definite cultural function to it. Thus, in connection with magic, we find stories which are not intended to *explain* the ritual or the phenomenon governed by magic, but are meant to substantiate the belief in magical efficiency. All such stories give us an account of an extremely successful, miraculous precedent. Around the various religious rites and ceremonies, there cluster stories which vouch for the efficiency of the religious acts in obtaining the desired effect.

Again, we have a class of myths which confirm the existence of privileges, give the antecedents of rank and power, or enforce duties and which, in general, strengthen traditional law and order. Wherever myth, that is a sacred story, has been studied in connection with the sources of its sanctity as well as with its sacralising results, it can be shown that it has served to strengthen faith by reference to an original Golden Age, to miraculous precedents in the dim past. The study of myth in conjunction with ritual and institution has been carried out only in limited areas; *e.g.,* in the Andaman islands (A. Radcliffe-Brown), in Central Australia (Spencer and Gillen), in Melanesia (B. Malinowski), in Northwestern America (Boas and others), in Polynesia (Elsdon Best). All the facts we know, however, prove that myth is in no way comparable to primitive science, but that instead it functions as a religious warrant, vouching for the truth of belief, the efficacy of ritual, and the fitness and justice of moral or social duty.

THE IDENTIFICATION OF CULTURE

The functional method seems at first sight to be of especially easy application to artifacts, to material objects fashioned by man for his cultural uses. Food stuffs ready for consumption, man's equipment in protective shelter and clothing, his tools and weapons, are all obviously means to an end.

The Place of Artifacts in Culture.—But this very facility has its dangers. The purposive character of most artifacts has made the *implement* into the typical representative of material objects; hence, all these have generally been regarded as representing the *technique* of culture. It is deemed sufficient to state how these objects are *made* and how they are *handled.* In *Notes and Queries* one-third is devoted to "technology," the description of manual production and of the handling of artifacts. In the *Handbook of Folklore,* this study is defined as an anthropology with technological considerations cut out. All this is incorrect, since "material culture" is not an autonomous, self-contained province of culture, such as religion, law or economics, each of which fulfils a specific function. Material culture is an indispensable accessory of every single aspect, every pursuit and institution, and thus fulfils a general function.

On the other hand, the bald technological treatment is not sufficient to do justice to any class of artifacts. The objects of immediate consumption or use, as well as tools and implements, are essentially correlated to economics and must be studied within its context. The proper analysis of a weapon immediately leads to the description of the manner in which it is wielded, thus to the methods of warfare and war magic and, finally, to the political organisation of the tribe.

There is no single type of human activity without its material accessories. There is not one artifact, however practical or simple, which could be properly understood without its context of living culture, including belief as well as technique, social organisation as well as traditional knowledge.

Once we begin to define form by function, the two categories of meaningless form and of fortuitous coincidence break down completely. An object can be defined and identified only by its use, the study of use leads us again to connect the object with the pursuit, the institution, the aspect. The real identities of

culture appear to lie in the organic connection of its parts, in the function which a detail fulfils within its scheme, in the relation between the scheme, the environment and the human needs. Meaningless details disappear, shape becomes alive with meaning and with function, and a testimony of irrelevant form falls away as worthless. The method of formal treatment breaks down completely.

Summary.—The outer framework of material culture is correlated in a clear and direct manner to the satisfaction of man's biological needs. It constitutes the *milieu* which man evolves to interpose between himself and the rigours, dangers and insufficiencies of his physical surroundings. But this material apparatus has to be operated by men collectively, organised and controlled by the body of tradition, scientific as well as religious and magical. Thus indirectly most elements of social cohesion as well as certain beliefs and ideas can be correlated with man's primary needs, and explained by the biological function which they fulfil and the survival value which they possess. But this is not sufficient, and here an extremely important addition has to be made: the facts of social organisation impose certain conditions upon human behaviour, imply restrictions and create new wants, which again call forth specific cultural arrangements. Thus, higher forms of organised labour need some compulsion, supplied by political inequalities, and some moral framework, supplied by certain forms of magic.

Mental development running side by side with higher technical ability brings about fear, thought and reflection which make man anticipate his destiny and probe into the past and future of his world. The beliefs of primitive man about future life, the beginnings of the world and spiritual powers have to be correlated with his increasing mental outlook as well as with the widening social horizon and the development of cultural values. Social cohesion requires some means of enforcing the various rules imposed upon the individual for the common good, and this brings about the sanctions and inducements, which constitute the essence of primitive law. In all this the functional view avoids the effort of attributing priority to any one aspect of culture. Material objects, social grouping, traditional and moral values, as well as knowledge, are all welded into a functional system. To explain any item of culture, material or moral, means to indicate its functional place within an institution, which has to be thus explained with reference to its aspect and this again has to be placed within the system of culture.

Finally, anthropology hopes, with the help of her sister sciences, to state the place of culture in the scheme of organic evolution; to show how it is correlated to the instinctive animal equipment of the human species; to demonstrate how it has allowed man to rise above the brute level, to control his surroundings, to develop his knowledge, his faith and his conscience.

SOCIAL ARCHITECTURE comprises all buildings for human residence, recreation, entertainment or health. In this work, several of these are discussed under their own headings; thus the reader should also consult HOSPITAL PLANNING, HOUSE PLANNING, STADIUM, and THEATRE ARCHITECTURE. This article is concerned with contemporary developments, in the designing of private dwellings, apartment houses (flats), and hotels in Europe and the United States. *See* also ARCHITECTURE and the comprehensive list of related articles under the heading ARCHITECTURAL ARTICLES. (X.)

I. DOMESTIC ARCHITECTURE IN EUROPE

Domestic buildings have always furnished a clue to the manner of life of their inhabitants; first of the individual, then of the community of individuals, and finally of that grouping of com-

munities which forms a nation. They are something almost of the soil, since they are so much something of the race. Domestic architecture has always reacted to outside influences, but fundamentally it has developed in a much more local way. Each section of a country, with its own individual habits and traditions of living, has had its local expression of domestic architecture, and yet all these varied expressions have had something in common, namely a reflection of the mental outlook and the physical customs of each individual race of peoples. Outside influences have tinged development, but no one country has ever completely mislaid the national characteristics of its home building. Very gradually, however, as international relations have increased, the barriers of race have been lowered, and the domestic architecture of one country has reacted increasingly to the influences of another. To-day intellectual movements spread with growing rapidity. Interchange of ideas makes for greater community of outlook; and in architecture there have crept in certain features which are a common expression of requirements shared by people in many countries.

England.—English domestic architecture provides an illustration of this theory, though house building in Great Britain has for so long set a standard to the world that it has itself been a main source of inspiration, and as such has latterly been comparatively immune from foreign influences. Prof. Santayana, in his essay on "English Architecture," mentions that "strictly speaking, there is no English architecture at all, only foreign architecture adapted and domesticated in England. But how thoroughly and admirably domesticated. . . . How gently, for instance, how pleasantly, the wave of Italian architecture broke on these grassy shores!" This appreciation is a very true one. Foreign influences, beginning in Norman times, working through the various phases of Mediaevalism, and the Dutch and Italian importations, to the periods of Classic Revival, have all left their mark on English domestic architecture. But always these influences have been absorbed and transmuted into something so removed from the original prototype that the result has become a national expression.

English domestic architecture stands pre-eminent; and that is largely owing to the presence, from whatever influences derived, of certain precious and peculiar qualities: a natural and unaffected use of beautiful materials; an intimate sense of scale, bringing English homes into a beautiful relationship with the countryside; a simplicity which rejects pretention and pomp. The home is a place designed to live in, and not primarily to receive in. England's Jacobean and Queen Anne houses are at once naïve, friendly and intimate, with touches of quiet fancy in the detail of tall gables, chimneys and carved panelling. In Georgian houses there is a warm friendly brickwork, an air of breeding and gentility in the quiet formality of the charming fronts behind which lie rooms at once so convenient in shape and so affable in decoration. In the 18th century there is just a touch of pedantry, which is less display of learning than intellectual good humour; then comes the period just preceding our own times, which has provided the one real menace to a continuity of fine tradition. This break was due to a variety of causes: to a 19th century "revival" of Greek and Roman architecture, from which resulted the outcrop of pseudo-Italian "villas"; to the teachings of Ruskin as misinterpreted first by an eager band of seekers after architectural truth, and afterwards by speculating builders. Or, which is more likely, to the change in social conditions brought about by the great industrial era of the 19th century, dominated by the advent of machinery and characterized by a degradation of the human ideal. Architecture reflected the human characteristics of the time and these were not of the type which would promote beautiful qualities in architecture.

This period has finally ended through a series of sane reactions, brought about by a change of outlook. Three men took a prominent part in this reaction, and their influence is responsible to a large degree for the present high standard of English work, based once more on the national traditions which respect locality and materials and pleasant manners as attributes of house building. These men were Philip Webb, Eden Nesfield and Norman Shaw, who evolved, severally, a type of architecture which inspired many architects to carry on the work of restoring English domestic building to its former high estate. Webb and Nesfield designed in a personal way, particularly the former. His work had at times a Gothic flavour, yet it reflected the more vital influences of his day, when William Morris was becoming a power in the field of art. Webb collaborated with Morris, and his first important house, the "Red House" at Bexley Heath (1859), was designed for Morris himself. This house reflected a mixture of both Gothic and Renaissance, and in its freedom of treatment marked the beginning of a modern school of design. Nesfield also passed through a Gothic phase, and later worked in a free style which was inspired by the Renaissance and the 18th century. He designed in particular, in 1866, a house in the Queen Anne manner which had a considerable influence in popularizing this dignified and homely style amongst younger architects. Norman Shaw was an architect who designed according to the requirements of character and site, and his work ranges from romantic blendings of brick, stone and half-timber, to the dignified simplicity of such plain London fronts as are found in Lowther Lodge in Kensington and his houses in Queen Anne's Gate. In his small houses in Bedford Park, Shaw set a model for dignified design in estate development.

Greatly influenced by Norman Shaw, the late Ernest Newton maintained a high standard in domestic work which was always simple and generally rather formal. His work was less personal than that of his well-known contemporary, Sir Ernest George, whose houses sometimes reflected foreign influences. Pre-eminent to-day stands Sir Edwin Lutyens, who has designed in nearly every material, and has touched the keynote of nearly every traditional English style. Guy Dawber's interesting houses are designed in the simple picturesque idiom—with stone walls and slate roofs—of the Cotswold district, Gloucestershire. Sir Edwin Lutyens and Guy Dawber typify the best English domestic designers, who prefer to use the materials and idiom of the locality where they build.

There is to-day a movement towards larger windows and a reduction in the actual size of houses, which has led to designs that depend less on wall surface and more on window grouping. Coupled with this external effect is a great improvement in planning, great compactness and arrangements for "labour saving" through the elimination of long passages and badly lit spaces. The design of English homes has become more scientific, and with this is a tendency, somewhat pronounced amongst younger architects, to design in a formal manner, the external treatment tending to a type of Georgian rather than to the picturesque type. This is largely due to the abuse of the latter in the hands of speculating builders. In small and large country houses, and in the homes in the "garden suburbs" and "garden villages," estates which are laid out to provide ideal conditions of domestic life, English architects are without superiors. Town houses are well designed, combining 18th century elegance with modern conveniences. The advanced modern movement, with its cubist tendencies, has made little headway in England. There are, however, a few examples, such as the houses designed on the Silver End Estate, near Braintree, by Thomas Tait. This type of house is not, however, particularly well adapted to the English country-side, and presents few practical advantages over the traditional type of house which has developed so naturally from local materials and requirements.

France.—France is a country which offers widely varying climatic conditions. These directly affect the type of domestic architecture; in the south is a warm climate, and we find a typical southern architecture of flat tile roofs, simple thick walls, shuttered windows and shaded eaves. In the north we find steep roofs and an architectural treatment which by its own richness attempts to impart the warmth and interest which the southern sun supplies. Yet in north and south alike we find common characteristics which are national.

In the France of former days, farms, manors or châteaux formed the bulk of the larger detached country residences, and for the rest domestic life was lived in villages in which the houses often formed a continuous street. Community life flourished in French towns and villages, and it has developed in modern times

into life in the large and small apartment houses which form the bulk of domestic building in larger French cities. To-day the château has given way to something more approaching the large English or American country house; the house of the notary or the doctor still remains to recall the architecture of the châteaux, in whose image it was so often built. The town houses of the aristocracy, which were in reality châteaux in town, separated from the street by a courtyard and stables with their main frontage on the garden beyond, have been replaced by the smaller town house, the *hôtel particulier,* not unlike the London town house in scope of accommodation, but very often an entirely detached and independent unit.

Whatever the category of building, practically every French home reflects a dominant French characteristic, the taste for an architectural arrangement permitting a certain degree of grandeur and display. This may perhaps be traced back to the traditions of French court life, the magnificence of Louis XIV. and Versailles. Certainly the homes of the French nobility reflected it in the formality of their planning. In modern French planning the tradition of splendour still persists. The French house takes definite account of the division of the plan into several units, those of reception, of living, of service. Each unit is treated characteristically and logically. The reception suite is open, with symmetrical rooms, wide doors from room to room, and more openings than wall space. Effect, not comfort, is the first consideration. The living quarters are more modest, and the services still more so. The best rooms are for reception; and inadequacy in this respect is rare.

In recent years, however, the English and American idea of comfort has permeated French ideas, particularly in the planning of apartment houses, in the design of which French architects have reached a high standard of attainment. The plans of the latest apartment buildings are remarkable for the easy and skilful arrangement of their rooms, for the clever utilization of often awkward sites and for the excellence of their services and sanitary conveniences. The entrance vestibule from the street and the main staircase are as a rule handsomely proportioned and excellent in the detail of their stucco and ironwork, and in the apartments themselves halls, corridors and cupboard spaces are usually on a generous scale.

The exterior of the typical modern apartment house shows a development from the 18th century or Louis XIII. type of front, of stone, or brick and stone, simple in general lines, crowned with a cornice and slated mansard roof, and relieved by carving and the excellent ironwork of the balconies. The latest tendency is, however, away from this classic type. Flat bay windows often continue up the whole height of the façade, and the roof line is broken up by receding planes with balconies and elaborate dormer windows. French building stone is soft enough to encourage carving, and the modern French apartment house has generally exhibited an abundance of carved enrichment, though the most recent tendency is toward a return to simplicity of treatment. The best examples occur in Paris, where there are many fine new apartment buildings erected in the quarter of the Etoile, Passy, Champ de Mars and Montparnasse. Some of the most stimulating examples are by the architect Henri Sauvage. German and Austrian influences have had their effect on these designs, which have in turn reflected the Art Nouveau and the sterner modern movement; but a certain lightness of handling in mass and detail has always remained in evidence.

The town house or *hôtel particulier* is tending to-day towards a modern character which rejects traditional forms. Large windows, plain surfaces and a general rigidity of form are in evidence, and a group of young architects, headed by such men as Le Corbusier, Mallet Stevens and André Lurçat, is erecting town houses in Paris and elsewhere which have little affinity with French tradition.

In respect of villas and country houses the same tendency is noticeable. At first inspired by local types, such as the tile roofed and half timbered houses of Normandy, the Provençal farms with their stone walls and flat tiled roofs, or the gabled and turreted buildings of the château country of Touraine, the French villa was a not always agreeable modern replica of a fine prototype. The modern movement has spread to a small extent to the villa and country residence, particularly in the south, where it is exemplified in the cubist houses of such designers as Djo-Bourgeois, which with their white walls, rectangular forms and flat roofs, recall the architecture of Tunis and Algiers.

French domestic architecture has undoubtedly been largely influenced by the academic training of the Ecole des Beaux-Arts: to its tradition in formal planning and design in the grand manner it owes its best feature, spacious and easy planning, and also its worst characteristics, which are an undue emphasis of architectural features, often unwise sacrifices to the principle of formal planning, and the retention in small work of architectural elements and embellishments which are more appropriate to a monumental building than to one of domestic character.

Germany.—The termination of the war of 1870 found German domestic architecture without a general directive tendency. On the one hand were those imbued with the ideals of the classic spirit, influenced by the public buildings of great exponents such as Schinkel, Semper and Von Klenze; on the other a group of romanticists inspired by the mediaeval spirit. The result has been a development along these two lines: buildings either in the style of a classical revival, or in continuance of the 18th century tradition; or in a free picturesque manner which has varied between serious renditions of mediaeval type and architecture of the pseudo-romantic type recalling the castles of the Rhineland. Into this war of ideals in expression has been interjected a third powerful influence, that of English domestic architecture, which was introduced into Germany largely through the efforts of the architect Hermann Muthesius, who was imbued with a strong belief in the creed of William Morris and believed that in the architecture of the traditional English house would be found the most fitting inspiration for modern Germany. At present there tends to be a reaction against the English influence, and two schools of thought predominate. On the one hand are those who look to German 18th century architecture for inspiration, on the other the extreme modernists, who are concerned less with style than with principles.

Amongst the architects who have carried out distinguished work on more or less traditional lines may be cited Ludwig Hoffmann, Alfred Messel, Paul Mebes, Albert Gessner and Bruno Paul. English influences are sometimes apparent in the houses of Hermann Muthesius, as in those of Theodor Merrill, Hans Liepe, Paul Bonatz, Heinz Lassen, Otto Bartning and others of the modern German school. There is no type of domestic architecture which can be classified as typical of Germany; as a rule however German domestic work is characterized by somewhat squat proportions, a certain massive quality of composition, emphatic roofs and heavy eaves. The tendency is towards solidity, and there is a general absence of light or fanciful detail.

Since 1914 there have been some interesting developments. A new school of architectural thought was in being prior to the World War, and manifested itself at the Cologne exhibition of 1914. Its tendencies were towards complete freedom in design, a return to the consideration of form, structure and practical requirements as the most important factors in architectural design. This movement, typifying an intellectual reaction against the often illogical restrictions imposed upon design by adherence to a chosen style, has been fostered by post-War conditions which imposed the strictest economy in building. The new architecture, reverting in its masses to the geometric constituents of architectural form, was well adapted to the demands of economy. As a result, in Germany at the present day there exists a school of architects whose work is completely modern in ideals, and has in consequence many points of similarity with that of modernists in other countries such as France, Holland and Austria.

Amongst architects of this modern school may be cited Arthur Korn, Peter Behrens, Richard Döcker, Walter Gropius, Ludwig Hilbersheimer, Mies van der Rohe, Hans Poelzig, Max Taut, Bruno Taut and Erich Mendelsohn. Their designs differ in character and expression, but in the majority of cases they have in common simple geometric masses, plain wall surfaces, large windows—as a rule in metal—flat roofs and an almost complete

absence of ornament. The work of Mendelsohn is in some directions the most original, but he is better known for his commercial than domestic work (*see* INDUSTRIAL ARCHITECTURE).

The new architecture ranges in expression between complete disregard of tradition and a type of design retaining simplicity while accepting certain traditional forms; in this latter category is the work of E. Fahrenkamp, O. Haesler and Thilo Schoder. That of the extremists in modernism was exemplified in an interesting manner at the Stuttgart exhibition of 1927, where houses by modern designers from Germany and other Continental countries were erected as an illustration of the contribution of modern architects towards the solution of the housing problem. The houses erected were in many cases too strange in conception to make a popular appeal, but as a practical experiment they undoubtedly served a useful purpose in providing data for the future. The standard of comfort and equipment in German domestic work generally is second only to that of the United States and—in respect of housing—England.

Holland and Belgium.—The Dutch architecture of tradition, like that of other European countries, is blended of mediaeval and classic or Renaissance influences. In domestic work its best and most characteristic expression is typified by the tall and elegant 18th century houses which line the canals of Amsterdam, and the crowstepped or curly gabled façades which reflect the earlier traditions. In the 19th century, and up to the commencement of the 20th century, these traditions were maintained, but with a gradual debasement as the spirit of individual craftsmanship and fine design became commercialized under the stress of modern conditions. The result of this degeneration was a reaction against tradition, a desire to create afresh in harmony with modern methods of building and commercialized production. An important stage in this phase of reaction was marked by the building in 1898–1903 of the Bourse in Amsterdam by H. P. Berlage, a building marked by simplicity and sincerity, depending for its interest on a straightforward outward expression of its plan and structure. Its material of construction (brick), maintained the Dutch tradition of fine brickwork, but in style it had greater affinities with a simple Romanesque architecture (*q.v.*) than with that of the Dutch Renaissance (*see* RENAISSANCE ARCHITECTURE). This building had great influence on Dutch work generally, and largely to the work of Berlage and his followers can be traced the most characteristic modern Dutch development.

The best contemporary Dutch domestic work varies between a version of traditional design, simplified and modernized, and a very modern architecture which is seen in its most characteristic form in the new housing schemes carried out in Amsterdam, Rotterdam and The Hague since 1918. In each case there is affinity with old work in the use of brick and tiles as materials, and in the painting of doors and shutters in gay colours. The new work depends for its effect on strong modelling of form, on the grouping of windows in long continuous lines, on simplicity in matters of decoration. Flat roofs are almost universal, windows are often placed on the angles of the façades and small details are sometimes given an eccentric turn in design which is not always pleasing. Strength and vigour, however, and a sense of rhythm and breadth, mark the new work and overshadow defects of detail, as in the buildings of such architects as J. J. Oud, P. L. Kramer, M. de Klerk, D. Greiner, J. F. Staal, P. C. de Bazel and W. Dudok.

Belgian architects have turned, like those of Holland, towards the modern movement. There are some interesting examples of private houses in Brussels and elsewhere, tending towards cubism and a general severity of line. Amongst architects who are producing interesting domestic work are Victor Bourgeois, A. Francken, Huib Hoste and Alfred Nyst. Apartment houses reach a good standard in Belgium, and in Brussels are some new buildings which are very up to date in equipment and luxury, in some cases containing baths, dance halls, cinemas, post office and shops, available to the tenants and the outside public.

Scandinavia and Finland.—In Norway, Sweden and Finland, there exists an interesting tradition of an architecture of wood. This has developed to-day into a domestic architecture which ranges from houses which have something in common with Dutch and Swiss architecture of a similar category to a class of substantial and well designed work which reflects the 18th century tradition more than any other.

In Norway are some excellent private houses constructed of wood, with vertical boarding as a covering and roofs of tile, with, in their details, a rococo feeling recalling the English Jacobean (*see* JACOBEAN STYLE); and there is also some good and simple modern work in brick.

Norwegian architects, such as Harold Hals, T. Astrup and A. Arneberg, have not achieved the international reputation of their Swedish confrères, who have carried out domestic and housing work which owes much to the 18th century, and Denmark in particular, but which is nevertheless modern in spirit. Ragnar Ostberg, Arvid Bjerke, Erik Lallerstedt and Ivar Tengbom are designers who have carried out houses of simple outline, fine proportions and charming detail. Swedish work is less heavy than that of Central Europe, and its modern buildings are unmarred by eccentricity.

Finnish domestic work has felt, to its detriment, the influence of the German version of the Art Nouveau movement, which resulted in an outcrop of extravagant shapes and florid decorations. In recent years, however, there has been a reaction towards a sterner architecture, and in Helsingfors and Abo are some good designs in brick and stone which are inspired in form either by classic or Romanesque tradition, but which in detail still reflect traces of 19th century German influences. Eliel Saarinen, Lars Sonck and Armas Lindgren are designers who are helping to create a modern Finnish national style, characterized by strength, but also by a crudeness which may be partially attributed to the extensive use of granite.

The most recent work of the younger school of Danish architects is tending towards a restraint and simplicity which approaches baldness, decoration being eschewed, with effect depending upon the interest of walls, roofs and openings. This work is always distinguished, but at times devoid of vitality. Paul Holsoe, Sven Risom, Paul Baumann, Aage Rafn and Kay Fisker are designers whose domestic work stands comparison with any in Europe.

Other Countries.—In domestic architecture the finest contribution of Austria is towards the solution of the housing problem, for in Vienna have been erected many large blocks of flats for the working classes which are excellent alike in equipment and architectural style. Provision of light and air, numerous balconies, fine courtyards, gardens and children's playgrounds are features of these new dwellings, which externally are simply designed in large blocks, depending on white walls and well grouped windows for their chief effect. In the realm of private houses are some interesting modern versions of the 18th century manner, by such designers as Josef Frank and Josef Hoffmann, as also buildings, which owe much to Tyrolese tradition, by the architect Clemens Holzmeister.

Czechoslovakia is making interesting contributions to the modern movement through such men as Jan Kotera and Josef Gocar, though some of the most recent domestic work is cubist in character and marked by eccentricity.

Switzerland also is feeling the modern movement. Swiss architects as a rule are happier in the 18th century tradition than in their more Germanic vein, though in Geneva, Zurich and Basel are apartment houses in the modern manner which compare favourably with contemporary work elsewhere.

Italy and Spain have contributed little to contemporary domestic work. Modern Italian apartment houses and villas often reflect a debased version of the classic tradition, with a reminiscence tending towards a modern cubism. Much modern Spanish work is extravagant and overornate, influenced by the more florid phases of the modern Continental development from the Renaissance. Barcelona in particular has contributed some remarkable efforts in extravagant modernism; this vogue is however on the wane, and there are evident signs of a return towards greater refinement and simplicity.

Few particulars are available concerning contemporary domestic architecture in Russia. Much fine work of classic and 18th century influence forms a nucleus for a possible line of development,

though it appears probable that the modern cubist school will strongly assert itself when building recommences on any scale.

II. HOUSING IN THE UNITED STATES

The term "housing" has developed a modern scientific sense that is more limited and specific than its original meaning, which was to provide accommodation for domestic life. In the first place housing implies the idea of furnishing homes to groups of individuals rather than to single individuals or to families alone. In the second place good housing implies that the best use has been made of each dollar of cost. So far as desirability is concerned, the house produced should be the utmost possible within the economic limits set. Housing is that science which devotes itself to the elimination of industrial waste in the production of homes, and attempts to utilize savings in improving the product. Scientific housing necessarily must consider the production of homes of varying size and cost to meet the economic requirements of the various groups within the community.

(A. C. HOL.)

DEVELOPMENT

The first type of habitation of the New England settlers was the crudest sort of dug-out, but it gave way almost immediately to a half-timbered house of traditional mediaeval design, with overhanging second storey, small windows and steep-pitched roofs. By the middle of the 17th century, in adaptation to the severe northern winter this type of house was covered with shingle or clapboard. With improvement in the mechanical facilities for sawing logs, the heavy half-timber construction was supplanted in the 19th century by a lighter form of wooden frame construction, still prevalent wherever wood or stucco is the chief material used. The wood houses of New England, the Dutch stone houses of the Hudson valley, the brick or stone houses near Philadelphia, the colonnaded houses of the South, and the adobe and Spanish houses in New Mexico and California represent the most important regional variations. (*See* MODERN ARCHITECTURE: *18th and 19th Centuries.*)

In the development of the seaboard cities the row house made its appearance early. It was usually two or three storeys high, built of brick and at first only two rooms deep. But as the need for further housing accommodations arose in the 19th century, and as land values increased, the row houses added an extra storey above ground and, to accommodate the furnace and the coal bin, sunk an extra one below. Frequently the plot became narrower, being reduced from 25 to 20 and even 15 ft.; and in the more pretentious quarters the open spaces in the rear were built over to create extra dining-room space, larger bedrooms, and inner rooms used as dressing-rooms, music-rooms and storerooms.

The row house built after the Civil War, with its narrow, dark and ill-ventilated rooms, its lack of sufficient open space in the rear, was without doubt responsible for the disrepute into which row-housing fell. The 19th century witnessed the introduction of three types of housing far lower in quality than was common in colonial times. From the log-cabin and the sod hut built by the prairie settlers no further developments in housing came. The second type was the so-called industrial or company housing, provided by textile manufacturers, mining companies and iron and steel industries in the new communities they created; with certain exceptions this type of housing became another name for monotony, depression and lack of hygienic and sanitary facilities. Finally, a third type was created, the tenant-house, a method of meeting the need for housing in growing cities by turning the single-family houses abandoned by the more prosperous classes into multi-family dwellings, without extra sanitary facilities, without privacy, without safeguard against fire. The tenant-house formed a transitional stage between the old individual house and the new tenement house created by urban land speculation and congestion.

War-housing.—With the sudden expansion of industrial activity in the munitions, ship-building and rubber industries during the World War, the need for adequate housing accommodations became acute. The commercial market could not command the materials or supply the demand. Accordingly, two Government war-housing corporations were formed, one under the Federal Labor Department, the other connected with the Shipping Board, and a fresh attack was made on the problem of supplying an adequate number of houses of good quality for the industrial worker. The war came to an end before many of the promising plans could be completed. But in the Seaside village, a project at Bridgeport, Conn., for which R. Clipston Sturgis and A. H. Hepburn were the architects, and in the Yorkship village near Camden, N.J. (Electus D. Litchfield, architect), definite advances were made in the plan, lay-out and construction of dwellings. Improvements in housing were co-ordinated with improvements in city planning (*see* TOWN PLANNING), in finance, in the establishment of a living wage, and in the provision for community services such as schools (*see* SCHOOL ARCHITECTURE), factors that had hitherto been left out of account or minimized by the conventional housing reformer. These experiments resulted in a more accurate knowledge of the costs that enter into the production of a dwelling house and of the social and technical factors involved in an effort to raise the whole level of housing above the massive depression and jerry-building of the past.

Modern Methods.—On the theory that methods which proved successful in war housing are equally applicable under peacetime conditions to promote better housing for the major part of the population, two separate initiatives in non-speculative group housing must be noted. One is that at Mariemont, a suburb of Cincinnati, O., built through the philanthropy of Mrs. Mary M. Emery, where a large tract of land was subdivided and plotted by John Nolen, and houses and small apartments of various types erected to meet the need of a varied income group. A somewhat different experiment under strictly urban conditions was initiated under Alexander M. Bing at Sunnyside Gardens, Long Island, N.Y., by the City Housing Corporation. In Sunnyside Gardens each block was planned as a unit, with individual houses and individual garden plots, grouped around a central open space to be maintained as common property for 40 years. The necessary garages were grouped at one corner of the tract, and a park of 3 acres was set aside as part of the original cost of housing. By the economies of unified planning, large scale

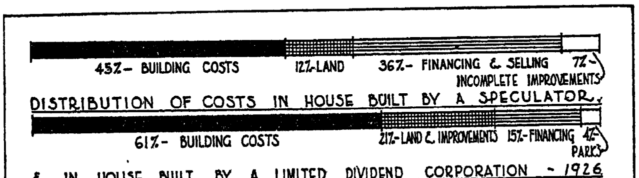
operations, group housing and more stable finance, it was possible to provide a substantial brick house of semi-fireproof construction, with more adequate open spaces for sunlight and recreation than are usually provided in a much more costly type of suburb. By limiting the profits of the corporation to 6% the houses can be sold and the apartments rented to workers with an income as low as $2,500 per year. The concrete difference between this kind of housing and that usually furnished under speculative enterprise can be put graphically in the following way:

Costs.—Note that in the speculative type of house, financing, selling expenses and profits account for 40% of the cost of the house, while the actual building itself absorbs only 44% of the total cost. The great improvement effected in the Sunnyside Gardens experiment consists in creating a much more durable and adequately equipped building which embodies in tangible utilities 60% of the cost; in reducing financing, sales-cost, profit from 40% to 16%, and in adding a new item, environment, *i.e.*, open spaces and playgrounds, as part of the original cost of the house. A good part of the effort to improve housing conditions has been directed toward economizing on the material, construction and equipment while leaving current methods of finance, sale and profits untouched. The experiment in Sunnyside Gardens demonstrates that much more substantial reductions can be made in the "intangible" costs of housing than in material construction.

Attempts to reduce the cost of housing in America have usually been attempts to reduce cost of the physical shell by lowering the quality of the construction. Where this can go no further, in outlying areas, the speculative builder uses cesspools, instead of municipal sewers, and neglects to lay down permanent roads or other services. These are all deceptive economies. They lower the original apparent cost of the house; but as soon as a neighbourhood grows, and municipal improvements are made, assessments and taxes to meet these necessary expenditures fall back upon the cheap house, and,—together with the high cost of repairs and upkeep, for flimsy construction wastes in annual coal bills more than it economizes on materials and labour,—in the end frequently drive out the original owner who is not prepared to meet them.

Genuine economy lies: (1) In economies in finance and sale. Through the provision of more social methods of finance such as the building loan association, the limited dividend corporation or, as in European examples, through Government loans at low rates of interest to associations that provide low cost housing of a certain minimum standard. The New York State Housing and Regional Planning commission found that in the cheaper types of housing the reduction of 1% in interest meant a reduction of one dollar per month per room in the rent of a dwelling. The reduction of the cost of money from the usual 9% in metropolitan centres to 6% would permit substantial improvements to be made in the ordinary house. A reduction from 7% to 6% in the rate of interest is the equivalent of reducing the cost of construction 10%. (2) Through improved community planning. By decreas-



GRAPH SHOWING HOUSING CONDITIONS IN THE UNITED STATES

ing the amount of money and space wasted through extravagant street planning, through the delayed purchase of park and school sites, through unnecessary public utilities, through the opening up of outlying areas for scattered development long before the necessary improvements can be economically supported, a more economic and efficient community plan that will protect the small house can be created. (3) Through larger initial expense in materials and fixtures; through the use of brass hot-water pipes instead of iron; of brick, hollow tiles and concrete instead of wood; and, in general, of more durable equipment, the ultimate cost of the house may be lessened. Finally, through large-scale operations, using row and group houses instead of free-standing individual units, a more substantial type of construction may be obtained with a smaller outlay. (*See* House Planning.)

One or another of these requirements may be effected in existing centres; to practise these economies on a great scale, however, involves the creation of new towns, such as that begun in 1928 by the City Housing Corporation for Radburn, N. J. Improvement in the quality of modern housing, with such decreases in cost as will make it available for the greater part of the population, requires a co-ordination of all the possible lines of advance. It is only in the newly planned garden city or satellite town that such a condition can be permanently provided. This does not mean that the shell of the house is incapable of improvement. It only means that the shell represents but 44 to 60% of the total cost, and that until attacks are made upon the remaining 56 to 40% as well, no very large improvements can be effected.

With the increase of the number of utilities in the modern house, with the recent introduction of artificial refrigeration and with the probable development in the near future of an artificial cooling system for summer, as well as a heating system for winter, it becomes more and more necessary to use machine work and standard equipment on all parts and connections that have hitherto been done by hand. Already kitchen cabinets are made in the factory. We may look forward to closets, and perhaps even whole bathrooms, being manufactured in the same way and installed as units. Along with this process will go a certain standardization of dimensions, so that linoleums and tiles will be cut at the factory for a standard floor, or stairs put together for a standard rise, precisely as doors and windows are now manufactured. In the mechanical installation of the modern house there will be less room for individual taste and caprice; or, rather, this will be exercised within a definite range of available patterns, subject to the usual changes of taste and style. The other line of development consists in the use of materials that have hitherto been unavailable on account of expense or difficulties of construction.

In the application of all these improvements to the separate units of a house there is the constant danger of bad design and of monotonous application of a single pattern. The remedy for this is not to do away with the improvements but to finance and build houses on such a scale as to provide for the services of the architect and community planner, who will use these separate standardized units as separate blocks in a comprehensive and imaginative design. In short, the depression and monotony of standardized designs is to be overcome, not by anarchic outbreaks of individual taste and "personality" but by the creative incorporation of parks, gardens and open spaces in every normal housing development. (C. S. St.)

MODERN PRACTICE

No house can be produced without the use of the four essential factors; land, credit, labour and materials, but in order that these factors may correctly balance one another there must be a design to govern their use. Altogether too little thought is generally expended on design. When trying to build a small, cheap house many people feel that they can not afford an architect. As a matter of fact, the importance of good design increases as the amount of money available to produce a family unit decreases. (*See* House Planning.) This applies not alone to the house itself but to group arrangement, and above all to the nice balancing of land values, credits and the physical house. The majority of work that in the past has served to provide shelter for the bulk of mankind has been executed with little or no understanding of the importance of design in this larger sense. Almost anybody who felt that he could enclose a house for less money than it could be sold for, has tried to do so. That part of the public with money to spend on essentials but not enough for frills has freely bought the product of the speculative builder and has in the main been dependent upon this unimaginative narrowly conceived type of housing. As to the large class of people who can not even afford to pay for essentials, it has generally been assumed that there were enough cast-off homes available to take care of their needs.

In spite of its failings, however, the average modern American house has mechanical equipment that provides its occupants with more comfort and conveniences than has ever before been available for the working classes.

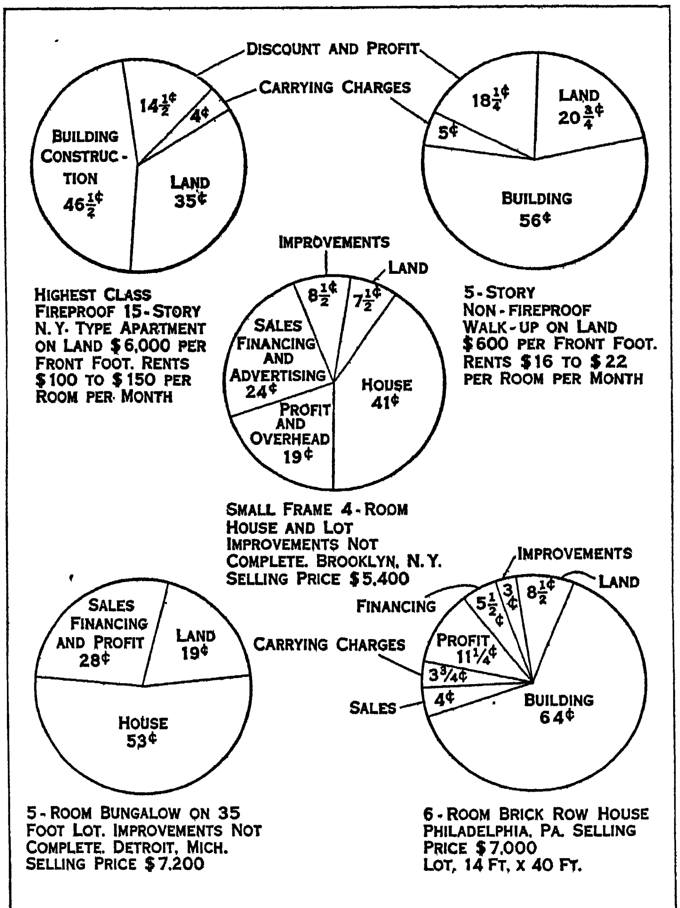
The first step in the direction of bad housing is generally the abandonment of a house by a family which could formerly afford to live in it. The occupancy of the house then changes to a number of families. Each pays a very little, but together they are sometimes able to pay, for the privilege of setting up makeshift homes in the old building, a total greater than the original cost. Since ancient times this has been the first method employed whenever the pressure of population in a rapidly growing city has created a scarcity of homes. The conversion of individual houses to multiple use increases the intensity of the use of land and therefore increases land value. Higher land values in turn provoke the second step in the direction of bad housing. It becomes necessary as well as profitable to erect new multiple dwellings instead of individual houses. Work is plentiful in the great centres of population and people are ready to put up with congestion to be near the source of their livelihood.

The movement into the cities makes city land desirable and tends to increase its value. More intensive use becomes an economic necessity. Fortunately there are natural as well as artificial limits to congestion. Except in times of great crisis or shortage people refuse to rent the most undesirable quarters. Consequently these are usually offered cheap, and some of them are kept filled only because there are always some families who, being able to pay practically nothing, must take what they can get. The average family that moves into undesirable quarters does so with the original idea that it is a temporary expedient until the breadwinner's luck improves. Some of them are never able to pull out. For this reason the State is compelled to step in, and, in order to preserve the standards of public health, to establish minimum standards of decent housing by act of legislature.

Restrictive Legislation.—Wherever there is restrictive legislation, there is a natural tendency to develop types of housing outside of the jurisdiction of the law. New York City has had its full share of this, especially since the World War, because of the great economic changes brought about by the change in the buying power of the dollar. On the more expensive land there has been the irresistible pressure to use the land more intensively. This has resulted in sky-scraper residential types carried, under the pretence of being hotels, to heights greater than those allowed for tenements, and the conversion of single family houses to multiple use without adequate fire protection, on the pretence that these buildings are intended for non-housekeeping use only. Though there are few cities which have developed exactly these methods for evading restrictions, in almost all growing cities where land values are increasing there is the well-marked tendency for the multi-family system to spread beyond the bounds controlled by law and the point of greatest activity will generally be just beyond the limit of restrictive legislation. For example, there has always been a great deal of undesirable wooden three-storey apartment construction going on just outside the fire limits of the greater city of Boston. Fire limits have been continually extended, but the activity in wood construction has always continued just beyond the limits.

Restriction increases the tendency to seek cheap land for development. New land is usually unimproved and frequently appears in the raw state to be cheaper than other available land where improvements such as sewer, water and other service facilities have been completed. For this reason, new land is subject to two faults in development. It is likely either to be developed too intensively or not intensively enough. The apartment is the chief offender in the first instance, for its courts are usually regulated by the legal minimums designed for more expensive land. Cheap land is usually remote land and too intensive buildings placed upon it depend originally upon vacant adjoining land for their desirability. Over-intensive development is likely to disrupt real estate values in the neighbourhood because the income from it is not entirely earned by its own land and buildings. In the outlying sections and in the suburbs this misplaced type of city apartment has become a real problem. This is not to be confused with the really desirable suburban types which are set in the midst of ample land and which are therefore not subject to rapid depreciation after the adjoining land becomes built up. A true suburban type apartment preserves the suburban atmosphere and holds out as the inducement to the longer travel, permanent recreational advantages of the out-of-doors.

As to the problem of new land which has not been developed intensively enough to pay for necessary improvements, the most conspicuous example is in Queens borough, outside the New York city fire limits. An illustration is given which shows the repeated rows of frame houses that have been erected beyond Jamaica. The outer sections of the city of Detroit have been developed in a similar manner. These houses are most of them uneconomic. It is only possible to build them because the financial set-up is misleading. They have been sold under the deceptive slogan, that it is always wise to "own your own home." Many who have bought houses of this type have learned to their regret that there are high discounts for original financing and high expenses for sales and promotion often running up to 43 cents on each dollar of original cost. On the maintenance side, also, there are high charges for rapid amortization and frequently unexpected assessments for improvements besides ordinary interest charges and taxes. Depreciation also is rapid so that the sum total of annual costs for carrying the houses is very great. As a result the inevitable movement to crowd two and three families in houses intended for one has already commenced, although most of the houses are not more than five or six years old. The accompanying diagrams indicate the proportionate shares of the average dollar spent for various representative types of housing, showing distribution to land, construction proper and promotion and finance.



HOUSING IN THE UNITED STATES. DIAGRAMS SHOWING THE PROPORTIONATE PARTS OF THE DOLLAR SPENT FOR "HOUSE," "LAND," "IMPROVEMENTS," "SALES-FINANCING" AND "OTHER EXPENSES" IN THE PURCHASE OF VARIOUS TYPES OF URBAN HOMES

The tendency to think of houses and of real estate as something quickly saleable has made it possible to offer so many

basically uneconomic and ill-considered types of housing to the public. The rise in the value of land has been depended upon to pay for the mistakes that have been made in the design and production of homes.

In recent years there has been a new type of legislation affecting housing. Of course prohibitory and minimum standard codes are still necessary, but enabling legislation has also been put into effect with the purpose of granting aids and encouragement for the production of better type homes. In England a direct cash subsidy has been extended to builders. In Germany the Government has underwritten second mortgages at very low rates of interest. In Austria the Government itself has constructed homes. In America New York State has gone farthest, granting limitation of taxation and establishing a State board of housing with supervisory powers.

Low Rental and Garden Developments.—During the emergency period following the close of the World War, a special act of the New York legislature granted permission to life insurance companies to invest a certain portion of their funds directly in low rental housing. Under this act the Metropolitan Life Insurance Company built multi-family dwellings in Queens borough, N.Y., with accommodations for 2,125 families (A. J. Thomas, architect). The rooms are small but the plan provides for permanent light and air. Since the completion of the buildings there has never been a day's vacancy in any apartment. The project has returned nearly 9% net on the total investment. There is no mortgage, but if first and second mortgages of the usual type were placed, the equity would return about 15% net, which is remarkable considering that rentals are $9 per room per month, from $6 to $4 under the market rate. The Metropolitan project is an example of what large scale planning, construction and management can accomplish. A. J. Thomas was also the architect for the project of the Bayonne Housing Corporation in New Jersey. The lower value of the land made it possible to plan still more openly. The buildings cover only 46% of the lot. At Bayonne the space in the centre of the block is large enough to be a real recreation space. Thomas has been given great opportunities to prove his contention that light and air do pay. He was also architect for a whole block of garden apartments on Mott avenue as well as the great block of Dunbar apartments for negroes built by John D. Rockefeller, Jr. in Harlem, N.Y., not as a charity but as an investment. The great co-operative projects, one by the United Workers Cooperative and the other by the Amalgamated Garment Workers, have been built in the Bronx, N.Y., from plans which follow the principles laid down by Thomas. The architect of the former is Herman Jessor; of the latter Springsteen and Goldhammer.

Along somewhat different lines and strongly influenced by the English garden city has been the work of Clarence Stein and his associate Henry Wright. At Sunnyside Gardens, Long Island, N.Y., which they designed, with Frederick L. Ackerman, associate architect, the detached house, the double house, the row house and the apartment have been combined. The ground is used even less intensively than Thomas advocates, and far more has been done for recreation and for community life. Boyd and Holden have also contributed to the development of housing technique and the latter's associate Leonard Cox has been the leading force in the design of tall garden plan buildings in New York. These latter are noteworthy because they carry the two-room deep type of planning into the high building and demonstrate that it is already possible at current market prices to plan for light and air on land costing up to $30 a square foot.

Housing is, of course, closely related to industry, as has been attested by the genuine concern that industry has shown in some cases for proper housing of its workers. Many companies have made the mistake of being too paternal and that is the reason for the odium which the term "company housing" calls up. Nevertheless, on the physical side some really constructive work has been done. Noteworthy are the experiments of the U.S. Steel Corporation at Gary, Ind., of Cheney Brothers, South Manchester, Conn., and of the Newport News Shipbuilding Co. in Va. So far as the future is concerned probably the most constructive assistance that industry can give toward the proper housing of its workers is in the influence that it can exert through the judicious use of its funds in lowering the rate of financing charges for well-considered and well-designed housing projects. The Bayonne Housing Corporation derives its funds from local industries that have endorsed this policy.

Forecast.—So far as the mass of men are concerned the home of the future depends on the development of the new housing science. If land is to increase indefinitely in value and is to be developed uneconomically and wastefully it is problematical whether the individual house will be able to survive, except as a luxury for the very rich, and in the great cities even the very rich may be driven to seek some desirable type of multiple dwellings as the inevitable solution of their home problem. The factors that will count are land, financing and the proper use of labour, and materials. Land must be properly used; financing costs can be reduced by lessening the speculative risks and doing away with too rapid depreciation. Much is to be hoped for along the lines of a more efficiently organized building industry. Much, too, is to be hoped for from the introduction of new materials and methods of construction. For example, at the present time, experimenters are trying to discover ways of making a practicable steel house and a practicable concrete house. Reinforced concrete which has been so successfully applied to industrial construction has at yet received only scant consideration as a medium for multiple dwellings.

Assuredly in the future large scale operations must come to the front. It must become possible to plan for a whole city block at once. In this way light and air will be permanently guaranteed and proper recreation space provided within the block. Cities of the future will have to depend on large scale operations to get rid of large sections of their areas which have been blighted by undesirable and uneconomic construction. The illustration on p. 880 shows a project worked out by Arthur C. Holden and Associates, architects, in consultation with the committee on the regional plan of New York, for the development of a great area of not less than five blocks which incorporates within the design complete educational, religious, athletic, social and recreational facilities for its residents. Some such attempt at orderliness must of necessity follow from the inconveniences, waste and chaos of present city life.

For the immediate future it must not be concluded that the general trend in housing from the individual to the multi-family house will put an end to the traditional American individual home at once. The American home may survive present tendencies. The point to be made, however, is that many of the individual homes that are produced to-day are a bogus product. The public must familiarize itself with the elements of scientific housing if it is to understand and to discriminate when it buys. If one-half the brains and energy that have been applied to the new automobile industry could be applied to improving the present type of housing, it would not take ten years to double the efficiency and desirability of the home that can be afforded by the average man. (A. C. Hol.)

III. APARTMENT AND HOTEL ARCHITECTURE

Apartment houses (flats) are buildings of compact and superimposed homes. In Paris in the 18th century, probably due to a need to house more persons in the space available, private

dwellings of several storeys were slightly rearranged so as to accommodate one family per floor. This led to buildings so planned before construction. Later, residential buildings were again altered, this time to provide quarters on each floor for two or more families. The space per family decreased as concentration increased.

The development of apartments has been intimately affected by that of the modern home. One hundred years ago the home was self-sufficient; moreover, it was fairly simple; its appliances and functions could be directed by anyone with common sense and willingness to work. To-day it is quite different. Most of its former functions are performed by specialized agencies, such as hospitals, restaurants, etc. Often it serves only as a place in which to sleep and entertain. Inventions have filled it with convenient, labour-saving devices. Rapid and smooth functioning at all hours is demanded. The apartment house, by bringing people together and pooling their interests, furnishes expert and up-to-the-minute service at relatively small cost per unit apartment. Its popularity has grown steadily; it is now familiar in practically all large cities of the western world; even small communities with ample room for lateral growth demand and build apartments. Paris holds the record for this type of building, its total of concentrated housing space surpassing even that of New York where the skyscraper apartment is common. In the United States, however, there is a marked tendency for apartments with gardens, restaurants, swimming pools, libraries, complete private facilities, to be produced in comprehensive units involving large areas in sections that are within walking distance of important centres but that would be irreclaimable without such planning.

There is no limit to the number of families that can be placed one above the other or on the same floor, but kitchens and toilets have to be provided for each. In many building laws, both in Europe and America, the apartment or tenement classification is based on the existence of these facilities. The kitchen is regarded as the principal fire hazard; therefore, building regulations as to the materials and methods of construction and the requirements for fire stairs, are made with reference to the number of kitchens. The kitchen thereby becomes the indicator of the family unit, except in the apartment-hotel, where it is absent. The only other restriction on the number of families in one building is that on the size of the building itself. (*See* ZONING.) In the United States, tall buildings are now made practically fireproof, but although diminished by the use of gas and electricity, and restaurants instead of kitchens, the fire hazard in an apartment is, of course, still greater than that in an office; consequently, the height of apartment buildings is more stringently restricted. There must always be two independent means of exit.

Apartment buildings are of two distinct types: the walk-up and the elevator or lift. Any building over five or six storeys requires a lift, and to be of practical value the lift must always work. Since no mechanical device is ever perfect, good planning practice requires the installation of a battery of at least two lifts in order to insure constant operation in case of breakdown. It might seem that the lift would change the planning problem only in so far as it makes more storeys possible. When there are only one or two apartments to a floor, either the lift or the stairway occupies a central location, and the apartments are planned around this vertical line of circulation as a starting point. But as the number of apartments per floor in the walk-up type increases, additional, separate lines of stairways must be added where needed. Lifts, however, being perpendicular shafts, are kept together so as to form on each floor a central distributing point to a large number of apartments. This requires special planning.

Planning.—In arrangement the apartment unit is not essentially different from the old-fashioned home, except that its several rooms must be placed with a view to convenient intercommunication, and must be reduced in size to the minimum. The living-room or parlour is the largest room, and opening off this, usually with wide doors which permit the occasional use of the two spaces as one, is the dining-room. Adjacent to the dining-room are the pantry, if one is included in the plan, and the kitchen. Bedrooms and bathrooms are preferably arranged in a wing of the building, so that they may be separated to some extent from the other quarters.

Modern bathrooms are small and very compactly arranged, one to each bedroom when possible. The kitchen has been reduced to a mechanical plant (*see* HOUSE PLANNING), doing more satisfactorily what formerly required a room 17 by 30 ft. in the concentrated space of 7 by 10 ft. When the building does not exceed 9 or 10 floors, a hand-operated dumb-waiter is installed, running from the basement to each kitchen, by means of which the janitor of the building distributes food supplies to the various tenants. Garbage is collected by the same device, although incinerators are also widely employed. The flues of the incinerator open into all the kitchens, and garbage and waste are emptied directly into them and reduced to ashes, which can be removed from time to time at the base. This disposal system keeps the dumb-waiter car and shaft clean. A gas-stove, an all-metal kitchen cabinet, a combination porcelain sink and laundry tub, an ice-box, and in recent years an electric ice-machine are generally installed when the building is erected. In America the use of an ice-box is almost universal, not only for cooling purposes during the summer heat, but because it helps to preserve food in a safe and sanitary condition throughout the year. The dining-room has one or more electric outlets convenient for toasters and electric grills on the dining-room table. The living-room often has a practicable fireplace, not for heating, but as a social amenity.

A single heating plant for each building or group of buildings provides the necessary warmth during the winter months, the system usually employed being steam with exposed radiators in all rooms. When the apartment building exceeds 10 storeys, the hand operated dumb-waiter is hardly practical. Electrically driven "fool-proof" dumb-waiters are sometimes used, but the initial cost is large and the upkeep expensive. In the most modern practice an additional service lift is installed. This is preferably located near the kitchen wing, or at the rear of the apartment house, to bring in food supplies, to remove garbage and waste and for similar services.

Light and an agreeable outlook are important factors in any place in which people are to live. Yet although sunshine is always an asset, large expanses of unbroken window surface are by no means desirable; just as in office buildings (*see* INDUSTRIAL ARCHITECTURE) too much glass surface, particularly in climates like that of the United States with its cold winters, causes economic waste in heating; but too little, of course, is even worse. Two windows to a room not on a corner is considered ample, and in bedrooms and minor rooms often only one is provided. The apartment should be so planned that cross ventilation can be had by opening any door. Because of the development and increasing use of artificial light in modern decoration, particularly in cities, large windows are often heavily draped much of the time; but it is important for each tenant to have at least one attractive outlook.

In the beginning, the particular appeal of the "flat" was the elimination of stairs. In the old-fashioned city house, built like a narrow slab in a block of similar houses, the overburdened housewife found the stairs very tiring, especially when there were six or seven flights from basement to attic. But this advantage in the flat was largely offset by the difficulty of separating living from sleeping quarters. The so-called "duplex" apartment was the first solution of this annoying problem. Here the entire apartment unit occupies two floors, the sleeping quarters above and the living-rooms below, with a small interior stair for communication.

In the effort to reduce space, since part of the care of a home is its size, a low ceiling was adopted. The New York building law at present specifies a clear height of not less than eight feet; formerly it was nine. Consequently builders anxious to get the maximum return from a given piece of property build to this minimum. Even the largest and most expensive apartments seldom exceeded 9½ ft., on account of the great waste of cubic contents in the minor rooms. This has resulted in the evolution of still another type of apartment, in which, by a combination of alternating "duplex" and "simplex" floors, the living-rooms

TYPICAL FLOOR PLAN OF 1148 FIFTH AVENUE, NEW YORK CITY

This plan illustrates the development of the high class apartment showing a completely equipped home in each unit. Note the adequate arrangement for natural light and cross ventilation and also the separation of vertical circulation between passenger and service elevators. Every available foot of space is advantageously used. The room called "Library" located adjacent to the living room and yet provided with closet and access to bath room makes its use possible as an additional bedroom. Most of the service rooms and service stair hall are placed on the interior court giving exterior light to the better spaces

are given an extra ceiling height, bringing them back again to the proportions of the old-fashioned city home, two storeys of living-rooms being placed adjacent to three storeys of minor rooms.

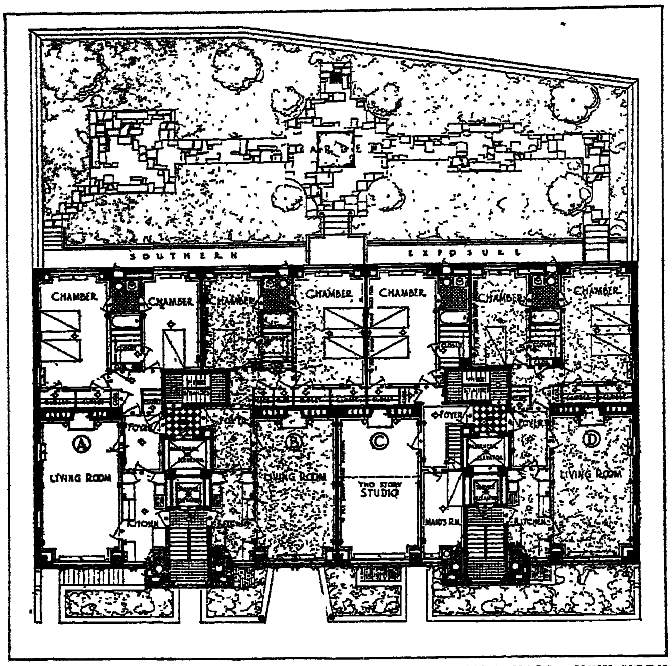
Exterior.—The exteriors of the first buildings erected for apartments were designed to simulate private city residences. This form, especially in districts where such residences exist, is still in vogue when the height does not exceed five or six storeys. It results from the designer's natural inclination to give dwellings, even when piled up, a domestic character. But when the number of storeys exceeds six the design problem becomes one of building masses, for which there is no precedent in domestic architecture and which makes a conventional domestic atmosphere practically impossible. Under the various modern building regulations, the sky-scraper apartment, like any other tall building takes more or less specified forms, and, to the casual observer, differs from the office building only in that it has fewer windows. The set-backs are frequently made into verandas, terraces and gardens on which French windows open. Where the roofs are flat over a sufficient area, penthouses are built and used as independent dwellings or as rooms belonging to the apartment proper immediately below, according as to whether or not the roof of the penthouse comes within the legal height of the building; with potted plants and small statues, the surrounding roof is then treated as a garden. (*See* LANDSCAPE ARCHITECTURE.) Although limited to relatively few tenants, dwellings of this character enjoy the quiet of the old-fashioned separated house.

Interior.—Its domestic character is generally given to a modern city apartment house in the treatment of its interior. In proportion to the mass above it the entrance hall is less spacious than that of an office building; its ceiling height may be kept down to the storey height of the building. It is generally carpeted and furnished as an elaborate lounge with provisions for a controlling office, telephone switchboard, etc. The decoration of the apartments themselves was formerly done in period styles, with elaborate panelling and ceiling effects, depending on the size of the apartment and the wealth of its tenant. The present tendency, however, seems to be away from this and toward the use of both colour and furnishings of a modernistic character. (*See* INTERIOR DECORATION.)

Forecast.—Modern life may be said to be an experiment in concentration, and it is, therefore, worth while to consider the possible results of increasing the concentration of both residence and business—presupposing, of course, that it can be accomplished compatibly with health and comfort. The problem is how to keep the principle of concentration with its economic and cultural advantages while so designing as to get for the individual the minimum travel and hurry, now the most distressing factors in urban life, and the maximum ease. To-day every city is trying to retain as much residence as possible in and near its business zones. Although zoning regulations may restrict business from a residential district, residences, without exception, can be built in business zones. This is done purposely so as not to submit everyone to the loss of time and energy involved in travelling to and from work daily; indeed, the traffic problem gives the strongest impetus to the present tendency to reunite residence and business. Successful attempts to decentralize, in which so-called satellite

towns are developed around the central city, have been made; but such towns, theoretically self-sufficient, seem to decrease as residential and increase as business centres.

Buildings whose bases would cover a large city square could be designed to house commercial enterprises and industries not involving disagreeable smells, noises, etc., in the lower storeys and



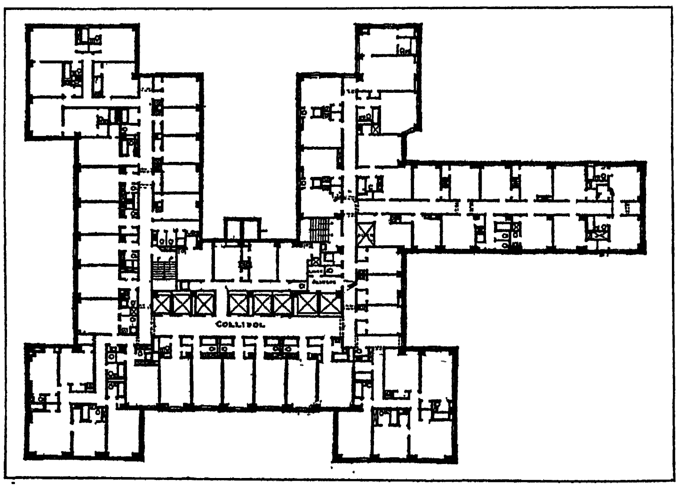
GARDEN PLAN AND TYPICAL FLOOR PLAN OF COLTON HALL, NEW YORK CITY; ARTHUR C. HOLDEN, ARCHITECT

above the first set-back, at the top of the first 10 or 15, the workers associated with them in residences of the apartment or apartment-hotel type, receiving the benefit of broad outlook, sunshine, and natural light and ventilation. A modern office building contains a dark core devoted to service mechanisms and surrounded by office units in horizontal layers. In the largest buildings to-day, most offices while receiving natural light are too deep from the outside wall for it to serve the entire unit; many workers, prevented by the windows from feeling shut in, have artificial light. Moreover, artificial ventilation when properly installed supplies cleaner and healthier air than is possible in the old-fashioned office, even with the windows open. As buildings are increased in size, the increased area of the office unit makes it possible for the workers to be more efficient and under better control per square foot of floor area without suffering inconvenience. Above the first set-back each storey would be recessed behind the one below which then would form, in front of each apartment, a terrace for the use of the residents. These upper storeys, in use and type of management, though not in disposition of spaces, would probably resemble the apartment-hotel more closely than any other present type, for the same economic forces that have driven people from private dwellings to apartments are beginning to turn them from apartments to apartment-hotels in which cooking is a communal service. The stepped and terraced tower would rise from the centre of the block. The interior of the tower, beyond the depth usable for living purposes, would contain communal rooms—dining-rooms, gymnasiums, libraries and radio, lecture, dancing and motion picture halls—all artificially lighted and ventilated. To secure the full benefit of sunshine during at least half the day, the whole building would be oriented north and south, like a ward wing in a hospital. Every room for living or sleeping would face east or west and on a terrace forming the roof of the floor below. At one end of the building block, logically the north, a service tower would rise with elevators or other form of vertical circulation connecting residence with business, pedestrian and traffic levels. Merchandise and people would move up and down through this tower through a series of superimposed landing stages (like floors with no enclosing walls) for aeroplanes, designed to rise and descend vertically, to deposit and receive passengers.

The atmosphere of the present industrial districts is too full of smoke and dust to permit such buildings; however, this condition is slowly being remedied. As cities become organized more communally they become cleaner; more consideration, too, is given to the importance of having plant life near. The well-planned city of the future will have many more parks than any city of to-day. In the giant building, trees, plants and flowers would be installed on the terraces and on a promenade just above the business area and running from block to block by means of bridges at the cross streets. The architect sees the city of 100 years hence as having smokeless skies, dustless air, residence and business reunited—business below in glass-enclosed spaces and apartments with terraced gardens above, all buildings oriented for maximum sunshine, light travel by air with landings on towers, heavy travel at street level, arcaded sidewalks one level up for pedestrians, bridges at this level and again at the living level for the convenient movement of pedestrians, machinery mastered to serve the health, comfort and happiness of man in all walks of life; order, cleanliness, rational disposition of space, sincere expression of structure and materials—the fundamentals of architectural beauty.

HOTELS

Originally, hotels were rambling structures with certain communal rooms—taproom, dining-room, parlour, with small offices on the ground floor and bedrooms scattered round in an irregular and commodious fashion above. Although the large, efficiently planned and highly organized modern hotels lack the domestic charm of their predecessors, the elements involved in hotel planning have changed in size and number only. The single dining-room has multiplied into a great banquet hall, a main dining-room, a breakfast-room, a grillroom, and oyster-bar and various special rooms; the parlour has been extended to accommodate conventions; ballrooms, galleries, swimming pools, gymnasiums and roof gardens have been added. The modern growth of the hotel has taken place mainly in the United States and may be traced to an enormous amount of business being carried on over an area so large that many commercial salesmen have to travel from place to place and conferences at central points have to be held, and to

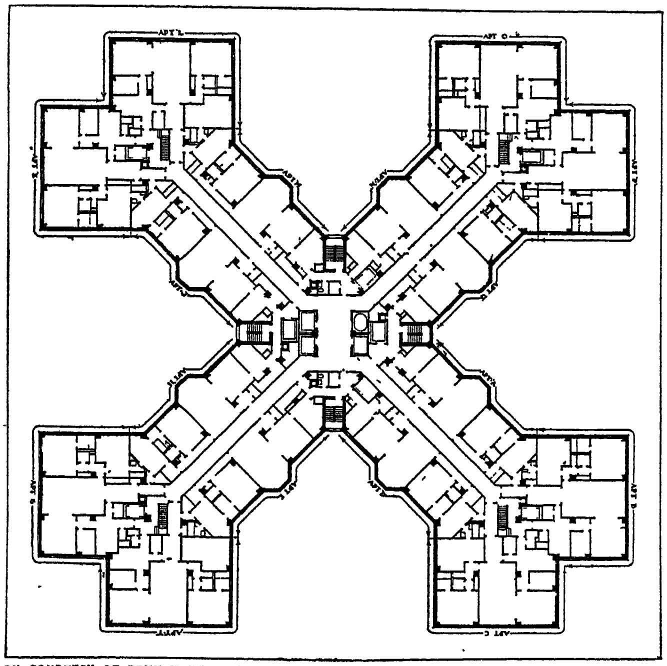


PLAN OF THE SHELTON HOTEL, NEW YORK CITY; ARTHUR LOOMIS HARMON, ARCHITECT

the modern developments in transport facilities which permits widespread travel for pleasure as well as business.

The modern hotel has to be designed to serve the needs peculiar to the modern travelling man of business. Efficient accommodation and time saving arrangements are more important than a domestic atmosphere. On each floor, at the entrance to the elevators, there must be provided space ample not only for circulation of the tenants but also for a control desk complete with key-rack and telephone switch-board. Each room must be equipped with a limited amount of closet space, a toilet, tub and

shower baths, hollow doors in which suits may be placed to prevent the valet's disturbing the tenant, inside and outside telephones, and in the most recent and luxurious even radios. The main lobby, however, is planned, even at the expense of efficiency, to suggest an atmosphere of bustle and a full house; the lanes through which visitors and tenants must pass should not be too wide, and convenient seating arrangements should be made;



BY COURTESY OF BRYN MAWR BUILDING CORP.

PLAN OF AN APARTMENT HOTEL

lobbies so planned have an added interest that may be non-existent if the disposition of space is the result of planning only for the greatest ease and directness of movement.

As in modern office and apartment buildings, a typical upper floor plan providing the greatest possible number of rooms in the space available, is developed first. The necessity of taking advantage of all outside space for rooms produces artificially lighted and ventilated corridors and halls; but wherever possible, especially at the points where tenants await elevators, natural light and ventilation should be brought in, for in enclosed spaces an occasional glint of sunshine and even a small vista relieves the prison-like aspect that many hotels have on bedroom floors. Steel skeleton construction, now the accepted form of building nearly everywhere (*see* ARCHITECTURE), makes possible a more economical bedroom floor arrangement than the older types of wall-bearing construction, with which, of course, there was also a definite limit to the number of storeys possible. The rooms and suites not provided in the upper storeys are much standardized. Since the desirable spaces in a sky-scraper are in the upper storeys, it is not uncommon for the first three or four floors to be occupied by quasi-public rooms, with shops and offices in the lower spaces, although examples exist where some of the public rooms have been put at the top; on the street level, shops open on both the street and the hotel lobby; these elements play an important part in meeting the high cost of operation. The heavy overhead expenses of a modern hotel makes operation with less than 1,000 rooms difficult. In the United States some recent examples exceed 2,000 rooms, 20 storeys are now customary and a 40-storey hotel has been projected.

The opportunities for exterior design presented are similar to those of other types of sky-scrapers. Zoning regulations, however, tending to cut the building back, interfere so materially with the standardized floor plan that the usual practice in the United States is not to carry the building above the permitted height for the straight front wall. This tends to produce a box-like form, and the architect, to soften its hard lines, has to resort to cornices and ornament, or develop roof-garden restaurants with pergolas. The entrance generally has a large marquise running out to the curb. The lower floors, devoted to large public rooms, give the architect an opportunity to express on the exterior, in an interesting treatment of the base, the major elements of the hotel.

From the interior point of view, the main lobby is the most important single feature in the building. It should be very spacious, since both tenants and visitors pass through it or congregate there, but, as has been pointed out, it should be so designed as always to appear busy and full of life. It is generally two storeys high with surrounding galleries. It is sometimes placed below a light well in the centre of the building so as to give some degree of natural light during the day, but in tall buildings skylights have little value and artificial "daylight lamps" are used above them to give daylight effect. Because of their large size the public rooms have to be formally treated, but their architectural formality is often successfully relieved by the use of screens of growing plants and the informal arrangement of the usually luxurious furniture.

The hotel is following in the way of other forms of business and is tending to concentrate in larger and larger units. In Europe, however, the height limit placed on buildings has prevented the adoption of the modern efficiency methods of hotel management with the result that it is impossible for enough typical floors to be superimposed for economic operation.

APARTMENT-HOTELS

Apartment-hotels have developed on a large scale from the modern demand for expert service in living conveniences that has tended to make hotels more and more popular as places of permanent residence. They differ from the apartment house in that the suites have no kitchens and the building generally contains one or more common dining-rooms. They differ from the hotel in that the rooms are not standardized and may or may not be furnished and they are designed without commercial spaces and many of the social rooms found in large hotels. Often tenants contract for their space on long term leases, furnishing and decorating to suit themselves. Sometimes dining-rooms are provided in the apartments, and then meals are served from the hotel kitchen. The management provides service at an hourly rate, thereby eliminating all domestic cares for the tenants. This type of apartment is prevalent in the United States, for there the idea of communal services is becoming increasingly popular.

The best source of information on modern apartment and hotel architecture is the various architectural publications, for which *see* bibliography under ARCHITECTURE. (H. W. C.)

SOCIAL CONTRACT. In political philosophy, a term applied to the theory of the origin of society associated chiefly with the names of Hobbes, Locke and Rousseau, though it can be traced back to the Greek Sophists. According to Hobbes (*Leviathan*), men lived originally in a state of nature in which there were no recognized criteria of right and wrong, no distinction of *meum* and *tuum*. Each person took for himself all that he could; man's life was "solitary, poor, nasty, brutish and short." The state of nature was therefore a state of war, which was ended by men agreeing to give their liberty into the hands of a sovereign, who thenceforward was absolute. Locke (*Treatise on Government*) differed from Hobbes in so far as he described the pre-social state as one of freedom, and held that private property must have been recognized, though there was no security. Rousseau (*Contrat social*) held that in the pre-social state man was unwarlike and even timid. Laws resulted from the combination of men who agreed for mutual protection to surrender individual freedom of action. Government must therefore rest on the consent of the governed, the *volonté générale*. Though it is quite obvious that the theory of a social contract (or compact, as it is also called) contains a considerable element of truth—that loose associations for mutual protection preceded any elaborate idea or structure of law, and that government cannot be based exclusively on force—yet it is open to the equally obvious objection that the very idea of contract belongs to a more advanced stage in human development than the hypothesis itself demands. Thus the doctrine yielding as a definite theory of the origin of

society to the evidence of history and anthropology, becomes interesting primarily as revolt against mediaeval and theocratic theories of the state.

SOCIAL HYGIENE. Although, strictly, social hygiene should deal broadly with all aspects of hygiene in a narrower sense than general hygiene which is the duty of the State and in a broader sense than personal hygiene which is the duty of the individual, the term, at the present time, is usually contracted in its significance to imply hygiene with respect to sex problems alone. Many branches of medicine, economics and government are concerned intimately with sex problems, *e.g.*, mental disease, national insurance, housing, recreation, education, alcoholism, drug addiction; but these, as such, are not included in social hygiene though their importance with reference to the question at issue is manifest. Nor do the different attitudes taken towards sex problems in different parts of the world, east compared with west, north compared with south, enter into the question, though obviously when a population is drawn from many widely differing sources such points must merit grave consideration. To a large extent social hygiene is a product of civilization and tends to be most highly developed in the most highly civilized countries. And yet it is not civilization as such, for in many ancient civilizations of high order social hygiene was but little prosecuted. Rather it is a product of the health and morality which are functions of certain types of civilization. Thus in the Mosaic Code, social hygiene in its modern sense is evident to a far greater extent than it was in Athenian civilization. In the main, problems of social hygiene are dealt with locally rather than nationally or internationally but the establishment of free venereal clinics shows that there is a national side while the concern of the League of Nations over the white slave traffic indicates the international aspect.

The recognized measures employed in the programme of social hygiene are educational, legal and protective and medical. The educational measures aim to promote among the general public an understanding of sex problems and of the best methods and experience in dealing with them, to promote sex education as a normal feature of character education, avoiding undue emphasis upon sex as such, and to promote the training of teachers, leaders of religious and social agencies and parents, for their task in the sex aspect of character education. The legal and protective measures are concerned with the repression of prostitution, the promotion of sound legislation and effective law enforcement in support of social hygiene measures, and of improvements in the organization and administration of police departments and of courts and institutions caring for sex offenders. They seek the prevention of delinquency through the development of desirable and adequate recreational opportunities, the use of women police in the supervision of public recreational facilities and through the extension of the preventive work being carried on by child guidance clinics, vocational adjustment bureaus, visiting teacher associations and voluntary protective agencies. Medical measures aim at the prevention and cure of the venereal diseases. The principal means employed are: instruction of the public in regard to the seriousness and the means of prevention of these diseases, and the necessity for early diagnosis and treatment of infected persons; the provision of facilities which are adequate and available for diagnosis and treatment; follow-up case work to encourage consistent attendance for treatment and to bring contacts of infectious patients under control; research for improvements in diagnostic and therapeutic procedures and materials; more thorough training of practitioners of medicine to deal with these diseases; and continuous study of the prevalence of the venereal diseases and the effectiveness of the various control measures employed.

SOCIAL INSECTS. Although the vast majority of insects are solitary in habit, there are certain groups in which the individuals have developed social behaviour and live together in societies. Each society consists of the two parent insects, or at least the fecundated female, and their offspring, and the members of the two generations live in mutual co-operation in a common abode or nest. Species which exhibit this mode of life are termed social insects.

There is little doubt that the social habit has developed out of the natural propensity of many female insects to lay their eggs in protective structures or burrows with ready access to food when the young hatch out. As a rule the parent then dies, but those species which survive the emergence of their young and, to a greater or lesser degree, also feed and protect them, merit the designation social insects. With solitary insects the usual brevity of adult life, once mating and egg-laying have been accomplished, precludes the development of the social habit. The first indications of the latter will necessarily follow, once the life of the female parent is sufficiently lengthened to allow of its having actual relations, however slight, with its offspring. In order to appreciate the full significance of the behaviour of social insects it is necessary first to consider the subsocial forms, or those in which the social habit is, as it were, in an elementary stage of its evolution.

SUBSOCIAL INSECTS

Insects with incipiently social or subsocial behaviour belong to diverse groups and exhibit parental care for their offspring in various ways. In the common earwig (*q.v.*) the female deposits her eggs in a group in an excavation below the surface of the soil and rests over them until they hatch. The young remain for a few days with the parent who in this respect resembles a hen with her brood of chickens, and her solicitude for her offspring is maintained until they disperse. Among the *Embioptera* (*see* INSECTS) of warm countries Imms has observed similar behaviour with the Himalayan species *Embia major* which lives in dense silken tunnels beneath stones. The young, in this case, keep together in the parental abode and, where necessary, extend it by weaving tunnels for themselves. Among beetles, in the Scarabaeid *Copris lunaris* the male and female associate in pairs and excavate a chamber in the earth which they fill with ellipsoidal balls of dung in each of which an egg is laid. These are guarded while the larvae are feeding and growing within, and when the young beetles emerge the latter are escorted to the surface by both parents and the family then disperses. Other species of *Copris* and also other dung beetles like *Geotrupes*, *Onthophagus* and *Minotaurus* exhibit very similar parental care, higher or lower developed in the several cases. The ambrosia beetles of the family Scolytidae (*see* COLEOPTERA) construct galleries in the wood of trees. Both sexes work together but most of the work devolves upon the female who excavates circular pits along the tunnels laying an egg in each.

Omitting the *Passalidae,* which also exhibit marked social habits, mention must be made of certain beetles of the family *Cucujidae* recently found by Wheeler living along with their brood in the hollow leaf-stalks of young *Tachigalia* trees in British Guiana. The parent beetles live and feed along strands of specially nutritive tissue and while they are thus engaged, numbers of mealy-bugs (*see* SCALE INSECT) wander into the leaf-stalk through the opening made by the beetles, settle in the grooves eaten out by the latter and feed on the nutritive tissue. The beetles lay their eggs and their larvae devour the same food as the parents but, remarkable as it may seem, both the larvae and their parents have learned to stroke the mealy-bugs with their feelers thus stimulating them to exude honey-dew which they eagerly consume. The beetle larvae duly pupate in the leaf-stalks and when the young beetles hatch out they remain with their parents, but soon commence egg-laying with the result that there is eventually a community of beetles, larvae, pupae and mealy-bugs of all ages living together. The subsocial beetles foreshadow the behaviour which obtains in the more highly organized social communities but, unlike the latter, they exhibit no structural or physiological differences between individuals which constitute separate castes.

SOCIAL INSECTS

Social Wasps.—It will be convenient to discuss the social wasps first because they are of special interest in illustrating the evolution of social behaviour. Collectively wasps (*q.v.*) form an extensive group numbering over 10,000 species, the vast majority

being solitary in habit. The social wasps, which alone concern us here, include about 800 species and are all members of the family *Vespidae* of the superfamily Vespoidea. Wasps are primarily predacious and feed upon other insects which they capture as their prey: they are also fond of nectar, over-ripe fruit, honey-dew, etc. Their mouth-parts have not attained the length and perfection found among bees, and hence wasps are unable to exploit the secretions of deeply seated nectaries. They construct paper nests formed of fragments of dry wood chewed and mixed with saliva: such nests consist wholly, or in part, of combs, or regular hexagonal cells, in which the young are reared simultaneously.

In oriental wasps of the genus *Stenogaster* some of the species are solitary, while others betray elementary social habits. According to F. X. Williams the social members of this genus construct small nests of comparatively few cells and the colonies comprise but few individuals. The female parent feeds the larvae from day to day until they are fully grown, when the cells are then sealed over: on emergence from the pupae the daughter wasps share the nest with the parent. In primitive African wasps of the genus *Belonogaster* the colonies are of larger size and in the stronger nests the older females devote themselves to egg-laying and the younger to foraging for food and nest materials. There is thus an indication of division of labour, but without any differentiation in structure among the females. *Belonogaster* is termed a polygynous wasp because each nest contains a number of fecundated females, and when a colony has attained its full development they leave in parties and found new nests elsewhere. Among certain South American wasps of the subfamily Epiponinae there is found the beginnings of caste differentiation: certain of the females are workers, *i.e.*, their ovaries are imperfectly developed and they are either sterile or capable only of laying unfertilized male-producing eggs, while others are true females or queens with fully developed ovaries and capable of fertilization. Since many of these wasps have numerous queens and their colonies are perennial, their nests become extremely populous comprising thousands of individuals. This overcrowding, however, is relieved by their periodically emitting swarms of workers accompanied by a small number of queens. Such swarms are the forerunners of new colonies and are unknown among wasps outside the tropics.

The most familiar social wasps are those of the genus *Vespa* which includes all of the common wasps and hornets of the north temperate zone. Since they are inhabitants of cooler regions, their colonies last for a single season only: swarming is unknown for the reason that this habit is an adaptation to the continuously favourable conditions of food and temperature that prevail only in the tropics. Furthermore, the colonies of *Vespa* are monogynous, each being founded by a single fertilized queen. At the end of the season all members of a nest perish with the exception of an annual brood of queens which, after fertilization, hibernate and each founds a new colony the next spring. A typical wasp's nest is composed of a fertilized female or queen, a large number of workers and a smaller number of males. The three forms of individuals are very alike in coloration, but the queens are considerably the largest: the males have seven evident abdominal segments and 13 joints to the antennae, whereas only six abdominal segments and 12 antennal joints are found in the queens and workers. The latter are a very distinct caste, being much smaller than the queen and incapable of fertilization: such eggs as they occasionally produce give rise to males only.

The hibernating female wasps are roused into activity by the warmth of early spring and commence to seek out likely situations for their nests. *Vespa vulgaris, germanica* and *rufa* make underground nests, other species suspend their nests from bushes, trees, etc., while *Vespa crabro* (the hornet) nests as a rule in hollow trees. In the very common species *V. vulgaris* and *germanica*, the nest is commenced by layers of "paper" being applied to the roof of the cavity in the ground destined to contain it. From the centre of the disk thus formed a stalk is provided and upon its widened free end the first few cells are constructed: they are hexagonal in form, open below and closed above. An umbrella-like covering is formed around the roof of the cavity to protect the comb and an egg fixed at the upper end of each cell by means of a cement, which prevents it from falling out. In a few days, according to temperature, the larvae hatch and are fed with chewed or malaxated portions of caterpillars, flies or other insects until fully grown. Prior to transforming to the pupa the larva spins a cocoon within the cell and closes the mouth of the latter with a tough floor of silk. The wasp grub now evacuates the contents of the gut for the first time and soon changes into a pupa. After four to six weeks from the time of egg-laying the adult wasps bite their way through the floors of the cells and emerge. These early individuals are all workers and they very soon take over the whole business of feeding the brood and extending the nest, so as to leave the queen free to devote herself solely to egg-laying. When the nest is fully formed it is more or less spherical externally and is invested by several protective coats of "paper": once a layer of comb has attained its full dimensions, new layers are built below and interconnected by vertical pillars. This goes on until about seven or more tiers of comb are constructed, and an average sized nest contains about 5,000 wasps towards the end of the season. In addition to the normal occupants a number of other insects inhabit wasps' nests either as inquilines or parasites and in the soil of the earthen chamber beneath the nest fly larvae live on the waste organic residue accumulated there.

Following this brief sketch of the habits of social wasps certain fundamental aspects of their behaviour remain to be mentioned. The feeding of the brood with malaxated portions of insects has already been referred to: the hungry grubs in the comb thrust out their heads, as Wheeler remarks, "like so many nestling birds," eager to attract attention from their nurses. It is now established that the activities of the latter are by no means disinterested and in return for the food supplied to their grubs, the wasps themselves eagerly imbibe the sweet saliva emitted from the mouths of their young. They stimulate the grubs by contact, or even by seizure of their heads between their own jaws, if the desired secretion be not forthcoming. This reciprocal feeding is termed "trophallaxis" which, as will be seen later, is of very general significance in the behaviour of social insects.

Owing to this expenditure of saliva by the larvae and the great number which are reared simultaneously, many are inadequately nourished and pupate as small individuals with poorly developed ovaries. In this manner it is claimed that the workers are produced, while the exigencies of collecting food for the larvae and caring for the nest is exhausting labour, which tends to keep them sterile. It is only later in the season that the abundance of workers and the amount of food brought in, allow of the larvae being more copiously fed, many of which in consequence develop into fertile females.

Social Bees.—Bees, as a group, are to be regarded as specialized wasps which have resorted to feeding upon nectar and pollen. Fully 10,000 species of bees are known, but only about 5% of them are social in habit, the remainder being solitary forms (*see* BEE). The special structural features of bees involve those parts and organs concerned with the gathering of nectar and pollen, and nest-building. The mouth-parts have well-developed mandibles, while the maxillae and labium are especially modified for sucking or lapping up nectar. Among the more primitive bees which visit flowers with exposed nectaries, the maxillae and labium are short as in wasps, but in the social and other specialized forms which visit tubular flowers with deeply seated nectaries, these same organs are greatly elongated, the ligula being drawn out to form the so-called tongue. The under surface of the latter is provided with a groove so overlapped by special hairs as practically to form a tube. Along this channel the nectar is sucked into the pharynx whence it passes into the crop or storage chamber of the gut. Here it becomes mixed with a ferment, presumably derived from the salivary glands, which converts its cane-sugar into invert sugar (dextrose and levulose). In this changed form the nectar is known as honey and it is regurgitated and served as food for the brood. The adaptations for collecting and gathering pollen are pronounced: the whole surface of the body is densely hairy and many of the hairs are branched or plumose so as to retain pollen

grains until the insect combs them off by means of its legs. The pollen is collected in masses and attached to the outer surfaces of the tibiae and first tarsal joint of the hind legs. These parts of the bee are broadened and fringed with long hairs to form a pollen-basket or corbicula. Another important feature is the production of wax, all social bees utilizing this material for comb-building and it is formed as a secretion which is discharged from glands between the abdominal segments where it hardens into lamellae.

The most primitive of the true social bees are the *Bombidae* or bumble bees. About 200 kinds are known and they are characteristic of temperate regions while in the tropics they are generally found in the mountains.

The societies of true bumble bees (*Bombus*) in Europe and North America are in most respects parallel to those of the social wasps of those regions, in that the fertilized females or queens, produced at the end of summer, hibernate and found new colonies in spring. On the advent of mild weather each queen seeks out a spot for her future nest which commonly consists of fine grass or moss formed into a hollow ball and located rather deep in the ground: some kinds, known as "carder bees" form surface nests concealed among herbage. Having formed the nest itself, the queen proceeds to gather a mass of pollen which is mixed with honey into a paste. Upon the top of this mass she constructs a circular wall of wax and in the cell thus formed she lays the first batch of eggs, afterwards capping it over with wax. She also constructs a waxen receptacle or honey pot which is filled with a store of honey for her own consumption, while she is brooding over the eggs to incubate them. The larvae hatch in about four days and feed immersed in their bed of pollen-paste and up to this stage the queen behaves much like a solitary bee. A significant change, however, supervenes and she gnaws a hole in the lid of the cell and regularly supplies her young with regurgitated honey and pollen, thus practising progressive provisioning. About the tenth day after egg-laying the larvae spin tough yellow cocoons and on the twenty-second or twenty-third day the first worker bees appear. New cells become added to the nest, each cell containing about a dozen eggs, and when sufficient workers have emerged the work of provisioning devolves upon them and the queen becomes confined to the nest. The workers construct additional receptacles for honey and pollen or store these substances in the empty cocoons: further new cells are added to the nest and the latter at its period of maximum strength contains from about 100 to 500 bees. Later in the season some of the larvae, enclosed in the larger cells, and derived from fertilized eggs, are abundantly fed and develop into females which subsequently hibernate: males, which develop from unfertilized eggs, appear about the same time. The workers do not differ from the queens except in size, and since they have been more or less inadequately fed during the exigencies of the earlier life of the colony, they are consequently smaller: any eggs laid by them are unfertilized and develop into males.

The nests of *Bombus* are often shared by inquiline bumble bees of the genus *Psithyrus*, each species of the latter adopting a particular species of *Bombus* as its host. Furthermore, the colour and size of a particular inquiline bears a strikingly close resemblance to its host species of *Bombus*. The inquiline species have no worker caste and their queens are devoid of pollen-gathering structures. According to Sladen the *Psithyrus* stings the *Bombus* queen to death and usurps her place in the nest, the *Bombus* workers rearing the inquiline offspring along with the reduced numbers of their brood.

The stingless bees of the genera *Melipona* and *Trigona* number nearly 250 species, which are chiefly found in South America, relatively few occurring in the tropics of the old world. The name stingless bees is a misnomer since a vestigial sting is present while, on account of their small size, they are sometimes called mosquito bees: when disturbed some kinds literally swarm over the face and in the hair of a human intruder to his great annoyance. The castes are well marked in these insects: the workers structurally represent the typical females except that they are sterile, while the queen exhibits degeneration of the typical secondary characters of her sex. The colonies are monogynous but a number of daughter queens are tolerated and these, accompanied by detachments of workers, swarm from time to time and found new nests. The latter are found in tree hollows or on branches; more rarely they occur in the ground or in termites' nests. Most species mix their wax with earth or other material, thus producing a brown or black substance termed cerumen for comb-building.

Social life among bees reaches its highest development in the hive-bees or honey-bees of the genus *Apis*. Only four species are known, viz., *A. mellifica* the common hive-bee, together with the oriental species *A. dorsata, indica* and *florea*. The common hive-bee (*Apis mellifica*) has been introduced into almost all countries of the world and is rarely, if ever, found wild in Britain. The three castes are very easily identified; as the drone (male) is considerably larger and stouter than the worker: it is readily distinguished by its blunter abdomen and the large eyes which occupy the greater part of the top of the head. The queen can be recognized by her much longer abdomen, which extends some distance behind the closed wings. Her reproductive organs are completely developed and attain a large size, whereas in the workers these parts remain rudimentary or occasionally become partially developed in the case of fertile members of their own caste. The colonies are perennial and a flourishing hive will number 50,000 to 80,000 bees, the vast majority of them being workers. The combs are made of wax which is secreted between the ventral abdominal plates of the workers. Each of the combs are composed of a large number of typically hexagonal cells arranged in two series placed back to back: the separate combs hang vertically downwards with just enough space between them to admit of the free movements of the bees. Cells in which workers develop are smaller than those destined to produce drones, while the largest are the royal cells, which are the cradles of the future queens. The royal cells are always very few in number, ovoid and irregular in form and are constructed by the workers as required. Other of the cells are used for storing honey and pollen which are drawn upon during the dormant months of the year. In addition to wax the workers utilize a resinous substance which they collect from the buds of poplar and other trees: this material is termed propollis and is used as a glue to fasten loose portions of the combs or for filling up crevices, etc. The queen lays an egg in each brood cell and the incubation period is about three days: the complete development of a queen occupies about 16 days, a worker three weeks and a drone 24 days. The fertilized eggs develop into workers or queens according to the type of feeding the larvae receive, and the unfertilized eggs produce drones. The young larvae, irrespective of caste, are nourished at first upon a food rich in protein, produced, it is believed, as a secretion of the workers' salivary glands. Queen larvae are fed upon this diet, which is commonly termed "royal jelly," until they pupate, while drone and worker larvae only receive this food up to the fourth day (or third day according to recent American observers), after which they are nourished upon honey and predigested pollen. The queen is able to survive for several seasons, but performs no functions other than egg-laying and is capable of producing up to 1,500,000 eggs during her life: her legs are destitute of the pollen-collecting apparatus so well developed in the workers. New colonies are established by swarming and this event follows the emergence of a daughter queen. The latter remains in the hive and the swarm consists of the old queen accompanied by a host of workers. The new queen takes her marriage flight at the first opportunity and is followed by a number of drones: mating takes place in mid-air and the fertilized queen then returns to the nest. If a second swarm be emitted the same season, it is accompanied not by the reigning queen, but by a new virgin queen. The worker bees when newly emerged are mainly active within the hive attending the brood, nest-building and performing other duties. As they become older they go out into the field in order to collect nectar and pollen: the latter duties are very exacting and summer-hatched workers seldom live longer than about six or seven weeks, while those hatched in autumn live to perform the labours of early spring.

It is important to remember that among bees social life exists

without that peculiar interchange of nutriment between the adults and their brood, which is so characteristic of social wasps. It is possible that the habit of using an abundant and highly nutritious food, and the storage of the same in reserve within the nest, ensures sufficient nourishment at all times for both adults and brood and thus renders exploitation of the latter by their nurses of little advantage.

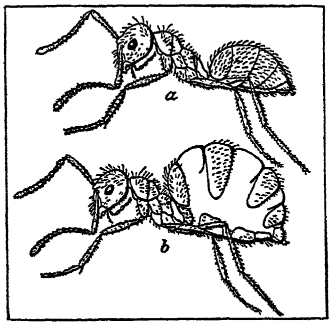
Ants.—It is among ants that social life in insects attains its highest expression and, it may be added, all ants are social in habit. Structurally they are easily recognized by their elbowed antennae and the conspicuous "waist" formed by a pronounced constriction of the abdomen where it joins the thorax. Except in certain individuals to be mentioned later, wings are absent and the mouth-parts are adapted both for biting and for taking liquid food. Ants live in societies which inhabit nests of various kinds: many species construct their abodes in the soil, galleries and chambers being hollowed out underground. Others form mound nests which are composed not only of excavated soil, but also of heaped-up masses of straws, twigs, pine-needles, leaves, etc., so arranged to form an orderly series of galleries and chambers. Perhaps the largest number of nests are simply excavated beneath stones or logs. In the tropics many ants take advantage of cavities found in stems, petioles, thorns, bulbs, etc.: others form suspended nests attached to trees and constructed of earth, carton or silk. The tropical ant *Oecophylla smaragdina* forms leaf nests, the leaves being fastened together by silk. Doflein and others have shown that the silk is provided by the larvae which are held by the jaws of the worker ants and used, as it were, as shuttles in weaving the silken threads, which bind the leaves together.

The larvae of ants are legless creatures with a small head and 13 trunk segments. When they become fully grown some ants construct cocoons which contain the pupae, such cocoons regularly being sold for bird-food under the name of "ants' eggs": other ants pupate without any such protection. No cells are constructed to protect the brood, the latter simply being contained in special chambers of the nest where they are assiduously nursed.

With the exception of the parasitic species, all ants possess a sharply defined worker caste composed of individuals devoid of wings with a relatively simply formed thorax, reduced compound eyes and with the simple eyes minute or wanting. As in other social Hymenoptera these workers are normally sterile females but on occasion their ovaries develop sufficiently to produce parthenogenetic eggs which may give rise to male or, in some cases, worker offspring. In some ants the workers are all alike, but in others they may be differentiated into large-headed or major individuals often termed soldiers, and small-headed individuals or minor workers: in other species there may be grades of individuals between these extremes. The males and normal females are winged insects with well-developed eyes but either sex may develop into abnormal forms of several types.

Under ordinary circumstances the queens cast their wings shortly after mating and the loss of the flight organs results in the degeneration of the voluminous wing-muscles, which finally break down into material which serves to nourish the developing eggs. When the eggs are mature and the first batch is laid, the queen attends the growing larvae, feeding them with her own saliva until they pupate. The workers which emerge then take charge, feeding the queen and themselves besides tending the new brood, thus enabling the parent to devote herself entirely to egg-laying. Winged males and females develop in large numbers in strong colonies and, given favourable weather conditions, they leave the nest and either pair with their brothers or sisters as the case may be or with individuals from other colonies. This flight provides for the dissemination of the species since the fertilized daughter queens usually found their nests some distance from the maternal colony.

The feeding habits of ants are both varied and complicated and it is noteworthy that hunting, pastoral and agricultural modes of life appear to have succeeded one another in these insects, as they are believed to have done in the case of man. As Wheeler points out, the most primitive species are carnivorous or, in other words, hunters of other insects. This habit is well exhibited in the tropical "legionary" or "driver" ants (Dorylinae) which do not construct permanent nests but wander about from place to place. These ants make sorties, often at night, for predatory and migratory purposes attacking insects, spiders and even vertebrate animals—especially if the latter be penned up. There are other groups of ants which represent the pastoral stage, such insects living mainly upon saccharine matter obtained partly from plants, but more especially as honey-dew exuded from Hempiterous insects. Many ants have learned how to induce these insects to void the honey-dew by stroking them with the antennae and even to keep and protect them—Aphides (*q.v.*) are especially sought after for this purpose and Linnaeus was amply justified in calling them the dairy cattle of the ants. This pastoral habit has led to remarkable specialization in species known as "honey-ants" which have discovered the advantage of storing honey-dew when it is available in quantity. Since ants, however, have not the art of making receptacles, they have adopted the curious method of using the crops of certain workers or soldiers for the purpose of food-storage (fig. 1). Individuals thus functioning are termed *repletes,* which become so inflated that they are quite unable to walk, and assume the rôle of animated casks or carboys. When hungry the ants stroke the repletes and receive from them droplets of regurgitated honey-dew collected during times of plenty. The habit above described has been observed in ants living in desert or other arid regions of Africa, Australia and North America, while a more direct vegetarian adaptation is found in certain other ants inhabiting much the same terrain. In such regions insect food is commonly scarce and certain ants resort to collecting and feeding upon plant seeds. These harvesting ants collect, husk and store the seeds in special granaries: in some species the soldiers or major workers appear to function solely as seed-crushers, thus allowing the softer parts to be available for consumption by the smaller individuals. The harvesting ants can hardly, as Wheeler says, be regarded as true agriculturists since they neither sow nor cultivate the plants from which they gather the seeds. There are, however, other ants which form the group of the Attiini, found in America from Long Island, N.Y., to Argentina, which may be looked upon as cultivators. They are fungus-growers and fungus-eaters and the fungi concerned are cultivated in gardens or special chambers of the nest. According to Moeller these gardens are practically pure cultures of the fungi, which are "weeded" and tended by the worker ants.



FROM WHEELER, "ANTS" (COLUMBIA UNIVERSITY PRESS)

FIG. 1.—AN ANT (PRENOLEPIS IMPARIS) MAGNIFIED

A. An ordinary worker; B. a worker greatly distended with a saccharine matter

When discussing social wasps the importance of trophallaxis, or the interchange of food between adult and larva, was stressed. Certain ant larvae supply their nurses with saliva while many exude a fatty secretion through the delicate general integument of the body, and larvae of the group Pseudomyrminae produce similar exudations from special papillae or appendages. These products are eagerly imbibed by the attendant ants, whose maternal care for their brood is, at least in part, initiated and sustained by what they receive in return for their attentions.

The relations between ant communities of different species represent another aspect of social behaviour. In some cases two species may occupy a compound nest and live amicably together although their broods are kept separate. Relations of this character are of the nature of social symbiosis, but in other cases the behaviour of one species towards another is one of aggression rather than of mutual benefit. The peculiar behaviour that is known as slavery or dulosis is especially well exemplified in the European ant *Formica sanguinea:* its workers raid the nests of *Formica fusca* and other species, carrying off to their own nests pupae from which workers subsequently develop. Such

workers live as slaves in the nests of their captors, but the latter are not wholly dependent upon them since independent slaveless nests also occur. Obligatory slave-makers or "amazons" are represented by another European ant (*Polyergus rufescens*) which is dependent upon its slaves, in whose nests its young queens establish their own brood. *Polyergus* invades a weak nest of *Formica fusca* and, after killing its queen, leaves the workers to feed and tend the amazon's brood. *Polyergus* workers are abundant but their sole part is to raid other *F. fusca* nests and bring back larvae and pupae for purposes of maintaining the slave population to the necessary level. Another European ant *Anergates atratulus* is a highly specialized social parasite with no workers, which lives at the expense of the species *Tetramorium caespitum*. The *Anergates* queen enters a nest of the latter and the host workers rear her offspring which are all males and females.

Passing now from the relations of ants as parasites and hosts of one another, there remain to be considered those cases in which they function as hosts for other creatures that live within their nests. These ant-guests or myrmecophiles include not only members of nearly all orders of insects, but also various mites, spiders, millipedes and land crustaceans which collectively number quite 2,000 different species. The nature of the association between these aliens and their hosts varies immensely. Some, such as certain bristle-tails, mites and rove-beetles are thieves or predators, giving nothing in return and devour dead or diseased ants or prey upon the brood. The bristle-tail *Atelura* is common in the nests of various European ants and according to Janet it obtains most of its food by imbibing it while it is being regurgitated by one ant to another. Other insects such as the curious slug-like larvae of the fly *Microdon* live as scavengers and at least confer some benefit upon their hosts. The true guests, or symphiles, come under a different category to the foregoing and mainly consist of various beetles which all show remarkable adaptations to their mode of life. These insects are tended with the greatest fidelity by the ants who rear their larvae like their own brood, notwithstanding the fact that they devour the eggs and larvae of their host. There are also a large number of Hemiptera and a variety of butterfly caterpillars of the family Lycaenidae which supply either honey-dew or glandular products highly attractive to ants. In many cases these insects are harboured in the nests while in other instances, where the association is less intimate, the ants follow them about on plants solely for the products which they yield them.

Termites.—The termites or so-called white ants are all, like the true ants, social insects living together in communities. Their social organization is of unusual interest not only because of its complex development, but also from the fact that although these insects are of very primitive structure, being closely allied to the cockroaches, yet their social life parallels in many features that of such highly developed insects as ants. Termites number over 1,200 species and abound throughout the tropics as well as occurring in most warm temperate lands: only two species are common in Europe and nearly 40 kinds occur in the United States. They are usually pale-coloured, soft-bodied insects with a delicate integument and may be readily separated from ants by the absence of any constriction or "waist" where the abdomen joins with the thorax. Their mouth-parts are very like those of the cockroach, the tarsi are almost always four-jointed and a pair of very short cerci are present. Certain members have two pairs of similar elongate membranous wings, which are easily shed by means of fractures at their bases, but the vast majority of the members of a colony are wingless. Metamorphosis is incomplete and often of a very trivial character.

Termites are insects of great economic importance since the chief food of a large proportion of the individuals is cellulose. In order to obtain this material they injure or destroy trees, crops, buildings as well as goods stored in the latter, thereby entailing immense losses to man, especially in tropical countries. Damage to wooden structures of all kinds is so extensive that the more progressive tropical communities are, where possible, replacing wood, especially below ground, by stone, concrete or iron. The nests or termitaria are very varied: the more primitive forms are wood feeders which construct no true nest but merely hollow out galleries in logs, decaying trees or manufactured timber. Other kinds burrow in the ground where they construct a labyrinth of tunnels either with or without mound nests above the surface. Among the higher termites, particularly those of Africa and Australia, the termitaria are often gigantic structures of great durability. They are formed of earth particles cemented together with saliva or with faecal material and, upon drying, the saliva-impregnated earth becomes of a cement-like hardness. Some of the most remarkable of all termitaria are the lofty steeple-like structures constructed by *Eutermes triodiae* in northern Australia, which are known to reach a height of 20ft. with a basal diameter of 12 feet. The interior of such a nest presents a maze of irregular chambers and passages while in its deeper recesses the brood is reared and the royal cell, which will be mentioned later, is located. The compass or "meridional" termite (*Hamitermes meridionalis*) is widely distributed in Australia; its nests attain a height of 8 to 12ft., and are flattened from side to side in such a manner that the broad faces are directed east and west, with the narrow ends north and south. There are other termites which construct carton nests of chewed wood, placing them up trees; such nests are ovoid or rounded, and about the size of a football or larger, and consist of an outer envelope enclosing a comb-like mass of internal passages. Many termites, which have to come above ground in search of food or water, construct earth-like shelter-tubes or passages, which run up buildings or trees often to a great height and are very characteristic features in the tropics. Secure in these covered ways they are able to travel long distances to and from their nests, protected from the daylight and from their enemies, but surrounded at the same time with the requisite humidity.

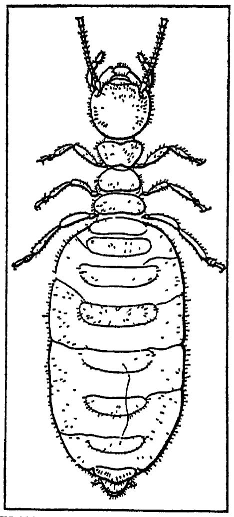
FIG. 2.—RETICULOTERMES FLAVIPES, FULLY WINGED MALE



FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTE)

FIG. 3.—RETICULOTERMES FLAVIPES, SHORT-WINGED QUEEN MAGNIFIED ABOUT 5 TIMES, WITH ABDOMEN SWOLLEN WITH EGGS WITHIN

Caste development in termites, although strikingly like that of ants, reveals certain important differences. Among termites the sexes are of equal social importance, since each caste comprises individuals of both sexes, whereas in ants the workers and soldiers consist of female individuals only. In most termites there are five castes, three being fertile reproductive castes and two sterile. The reproductive castes consist of the following:

(1). Normal winged males and females or *macropterous forms* (fig. 2) which have a firm dark integument and are usually known as kings and queens: the eyes and brain are large and the reproductive organs well developed. The wings are ultimately discarded and only their persistent bases remain.

(2). Less pigmented *brachypterous forms* (fig. 3) with pad-like or incipient wing rudiments. The brain, eyes and reproductive organs are somewhat smaller than in the first form.

(3). Scarcely pigmented *apterous forms* (fig. 4) with no traces of wings and with the eyes, brain and reproductive organs smaller than in (2).

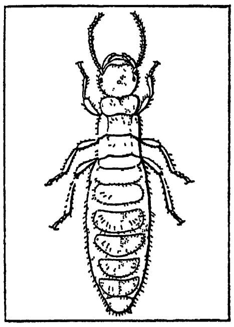
The sterile castes are wingless and in them the reproductive organs are imperfectly developed and non-functional, except possibly at times in the most primitive species only. They consist of:

(4). Unpigmented *workers* with the brain small and the eyes vestigial or absent (fig. 5). The head and mouth-parts are not exceptionally developed.

(5). Large-headed more or less pigmented *soldiers* with the brain small and the eyes vestigial. The mandibles are very large

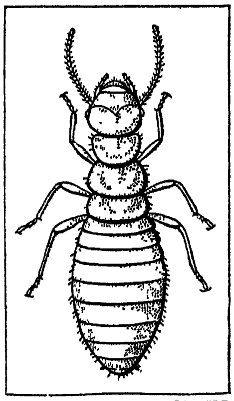
and projecting, varying in form in different species (fig. 6). In a few genera the mandibles are small and the heads retort-shaped, being drawn out into a rostrum bearing the opening of the large frontal gland at its apex: this type of individual is known as the nasute soldier (fig. 7).

Among the most primitive termites like *Archotermopsis, Termopsis* and *Calotermes* there are no workers and their functions are performed by the young soldiers and reproductive forms. In some genera there are major and minor soldiers, and occasionally intermediates also, while there are species with both large and small workers as among ants.



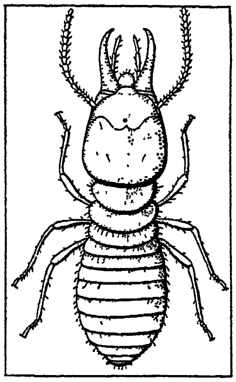
FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTE)
FIG. 4.—RETICULOTERMES VIRGINICUS, WINGLESS QUEEN, MAGNIFIED ABOUT 5 TIMES, WITH NO EVIDENT TRACES OF WINGS

The origin of termite castes has given rise to much discussion and Grassi followed by Jucci ascribe the differences between the several types of individuals making up a community to the influence of nutrition. Other authorities, however, have shown that, in some species at least, the young are separable into two types when they emerge from the eggs. Some individuals with small brain and eyes and with the reproductive organs in a very rudimentary condition, develop into sterile workers and soldiers; others with these several organs normally developed grow into fertile reproductive forms. Very early in post-embryonic growth further differentiation proceeds and all the future castes become recognizable by small differences exhibited by the young. In view of these facts it appears probable that among termites caste differences are due to intrinsic causes within the eggs, and are not modifiable by external influences. A remarkable feature in the lives of the more primitive termites which feed upon wood is the presence of enormous numbers of Protozoa in their intestines. Recent discoveries made by Cleveland, following upon the earlier observations of Bugnion and of Imms, indicate that the Protozoa are actually beneficial to the termites, apparently breaking down the wood devoured by those insects and rendering it in a condition capable of being digested. Cleveland has shown that by "sterilizing" termites of all Protozoa these insects are no longer capable of digesting wood and finally die, but if they be reinfected with these organisms their normal life and growth proceeds.



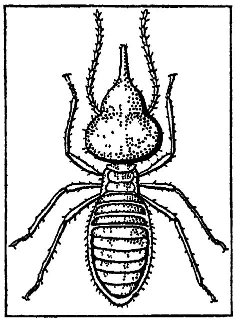
FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTE)
FIG. 5.—PRORHINOTERMES SIMPLEX, WORKER, MAGNIFIED ABOUT 10 TIMES

At certain seasons of the year the normal winged (macropterous) males and females issue from well-established colonies in great swarms and after coming to the ground cast off their wings. Enormous numbers are devoured by birds, lizards and other animals, while the few survivors pair and found new colonies. The mated couple—king and queen—excavate a small chamber in wood, in the ground or other situation, and remain together, feeding and caring for the offspring until enough workers or young nymphs have been reared to take over the duties. Mating goes on at irregular intervals, the king cohabiting with the queen for life. Among the more primitive termites large nests contain numerous kings and queens, but in the higher forms only a single royal pair is present. In such cases the queen develops into a huge inert egg-laying machine, incapable of locomotion, and remaining with her relatively tiny mate in a special royal cell where the couple are fed and tended by their numerous progeny. In species of *Termes* the queen may possibly attain a length of four inches and may lay 4,000 or more eggs a day and many millions during a lifetime of perhaps ten years. The brachypterous and apterous reproductive forms are usually regarded as supplementary royalties, which take the place of either of the original royal forms in the event of their death; possibly also they extend the colony or found subsidiary communities, but little is known on this point. These peculiar forms produce no winged adults among their progeny, but only their own types and the sterile forms. The greater part of the duty of feeding the brood and nest-building is performed by the workers, while the soldiers are mainly concerned with defence. The large-jawed type of soldier is apparently less efficient in this respect than the nasute soldier, the pungent secretion of whose frontal gland having a very salutary effect upon ants which, it may be added, are perennial enemies of termites.



FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTE)
FIG. 6.—PRORHINOTERMES SIMPLEX, SOLDIER, MAGNIFIED ABOUT 10 TIMES

The feeding habits of termites are both complex and remarkable. Living and dead plant tissues form the staple food but termites have also developed an elaborate system of mutual feeding or trophallaxis. They feed one another, and more especially the brood and royal forms, with regurgitated food, faeces and also saliva and there is also evidence that all castes produce exudations of glandular products from the skin, which are licked by other members of the community: since the queen produces the most copious and palatable exudation she is assiduously tended and licked by her brood. Some termites, like ants, store up food, especially lichens, fragments of grasses, etc., but the analogy between the two groups of insects is exemplified more strikingly in the case of fungus-growing termites. Certain of the higher genera form comb-like fungus gardens and their nymphs graze in these miniature fields like so many tiny sheep; the soldiers and workers do not use this food, but the royal forms are fed upon it like the young.



FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTE)
FIG. 7.—NASUTE SOLDIER OF EUTERMES COSTARICENSIS, MAGNIFIED 15 TIMES

The relations of termite communities of different species to one another have been comparatively little studied. Sometimes several species share a compound nest, but their respective galleries are kept separate, while some soldierless species have only been found in the nests of kinds in which that caste is present. A host of other insects or termitophiles live within the termitaria on much the same terms as myrmecophiles exist in ants' nests.

GENERAL REMARKS ON INSECT SOCIETIES

It is a remarkable fact, as Wheeler remarks, that among insects social habits have arisen no less than 24 different times in as many different groups of solitary insects. The various examples of this type of behaviour represent, as has already been pointed out, very different stages in the evolution of their social system. In the simplest cases only mere rudiments of social behaviour are evident, while at the other extreme are highly organized systems involving immensely populous communities, presenting many similarities or analogies to human society. Several writers have compared an insect society to a super-organism and, as Julian Huxley has remarked, the members of the community, although now functioning as parts, were descended from ancestors that functioned as wholes. The castes exhibit a differentiation of structure and function corresponding with the division of labour among the organs of an animal body. A single individual is incapable of prolonged survival apart from other members of an insect community, almost as the separate organs of an animal body are incapable of independent existence. The workers and soldiers may be looked upon as the body of the super-organism, while the fertile members, representing the germ cells, form the organism that ensures the continuance of the species.

One of the most urgent difficulties in communal life is the supply of food. The members of a colony need a regular, abundant and easily available source of nourishment. Certain of the smaller and more primitive insect societies feed upon animal food, but the more highly organized and densely populated colonies of other species as a rule resort to the more certain and abundant supplies afforded by the plant kingdom. The collecting and apportioning of food among adults and young, economy in its use and competition with other organisms in securing supplies, all seem to have contributed to the development of a special worker caste upon whom the onus of provisioning the colony rests. The reproductive instincts likewise present profound difficulties in communal life: unlimited exercise of this faculty would result in a population speedily overreaching its food supply and finally the disintegration of social life. The true social insects have overcome this difficulty because among them the full reproductive powers are confined to few individuals and aborted in the rest. Among the social Hymenoptera the colonies are essentially gynarchic, the female being the dominant sex: under this régime the males, apart from breeding purposes, are little more than social parasites. In the hive bee it is well known that after fertilization of the queen is achieved the luckless males are eventually driven out of the hive. On the other hand, among termites, as we have seen, both sexes participate in the life of the society, and in this respect they more closely resemble the human species.

The onset of social life has led to the development of communal nests wherein security is afforded to the inmates. The helpless, sedentary brood, massed together, is naturally fixed to a particular location and exposed to the attacks of enemies and changes of the elements. The need consequently arose for protective habitations or even fortifications of various types suited for special requirements. Those social Hymenoptera, endowed with wings and adequate stings, chiefly nest above ground while the largely wingless, and on the whole more defenceless, ants and termites have mainly sought protection in a subterranean life. Social insects are highly successful in the struggle for existence, as is exemplified by their abundance in individuals, as well as by the great variety of habitats they occupy and the extent to which such creatures as ants and termites have spread over the world. Tending of the brood by social insects has led to the intimate relationship that exists between the two generations, and consequently to the discovery by the parents of the palatability of the salivary or other secretions of their young. In this way trophallaxis or mutual feeding, previously quoted, has arisen, and the avidity of the parents for what their young have to offer them has developed in so many cases into a bond which has extended and strengthened social behaviour.

Social insects display an elaborate communism where individualism is submerged for the welfare of the community to a degree unattained in human society. Wheeler has stressed how tradition and social inheritance in man have enabled him to preserve and accumulate his capital of culture and advancement, whereas social insects have to begin each new colony anew only with the structural and instinctive equipment provided by true or organic heredity. In this difference he sees the explanation why so little change has taken place in social insects, although they were highly evolved before the origin of man. The distinction, he adds, is nevertheless not absolute, since social insects bequeath their nests, pastures and hunting grounds to successive generations. Insects have not acquired the use of tools, but, on the other hand, they are the only animals besides man that have succeeded in domesticating other animals, and even plants, as well as enslaving their own kind. Means of communication, although not through speech, have undoubtedly been evolved by means of the senses of smell and touch and also through sound production. In the tropics insect societies are of considerable duration and are liable to outstrip means of subsistence: just as the colonizing expeditions of man have gone forth to establish themselves in fresh lands, the swarming propensities of bees, wasps and ants are for a like purpose. Specialization of individuals to specific trades or duties in human society finds its analogy in the castes and differences of behaviour among the individuals of an insect community. Just as in man, the warrior caste has its place in insect society and defensive as well as attacking exploits are prevalent. The nests of social insects, like human habitations and buildings, afford food and shelter for alien creatures and many are more or less tolerated by their insect and human hosts. Insect societies, to quote again from Wheeler, represent final and relatively stable accomplishments which have developed along purely physiological and instinctive lines, and this instinctive basis, with the consequent absence of education and tradition, constitutes a fundamental difference between them and human societies.

Bibliography.—The whole subject of social insects is admirably discussed by W. M. Wheeler in *The Social Insects, their Origin and Evolution* (1928), which is accompanied by a full bibliography.

Subsocial Insects:—J. H. Fabre, *Souvenirs Entomologiques* (1879–1907), and the translation of parts of this work by A. T. de Mattos, *The Sacred Beetle and others* (1918). *See* also F. X. Williams, *Philippine Wasp Studies* (Bull. 14, Hawaiian Sugar Planter's Exp. Station, 1919); W. M. Wheeler in *Zoologica* (vol. iii., 1921); H. G. Hubbard, *Ambrosia Beetles of the United States* (Bull., n. ser., div. entom., U.S. Dept. of Agriculture, 1897); A. D. Imms, "On Embia major sp. nov. from the Himalayas," *Trans. SOCIAL INSURANCE: *see* National Insurance.

SOCIALISM is the name given both to a widespread body of doctrines and to a world-wide movement taking many different forms. It has a long history behind it; and the word has been used in shifting senses as the ideas behind it have developed and the situations facing it changed. A short and comprehensive definition is therefore impossible. We can only say that Socialism is essentially a doctrine and a movement aiming at the collective organization of the community in the interests of the mass of the people by means of the common ownership and collective control of the means of production and exchange.

It is well to begin by ruling altogether out from the scope of this article certain popular uses of the term "Socialism" which were current, especially during the past generation. The well-known phrase "We are all Socialists now," and the constant references to "socialistic legislation," only serve to obscure the real meaning of the word. "We are all Socialists now" only means that everybody in these days, whatever his politics, is ready to agree to a greater amount of Government intervention both in industry and in the affairs of society generally than most people even conceived as possible a generation ago. And "socialistic legislation" is, as a rule, only a phrase indicating disapproval of any measure which increases this collective intervention or seeks in any way to promote a more equal distribution of income among the members of the community.

Again, almost any extension of local government activity, such as the taking over of a tramway system or an electric supply station, or the establishment of a municipal bank, is liable to be referred to as "Municipal Socialism," even if the public body which does it consists mainly of persons who are strongly opposed to Socialism. Socialists certainly urge the extension of municipal trading; but so do many persons who are not in any sense Social-

ists. These and similar uses of the word are accordingly left out of consideration in this article.

We must, however, try to make our initial attempt at a definition somewhat more precise. Socialism, we have said, is the name given at once to a doctrine and to a movement. In its early days, before there existed any widespread or clearly-defined Socialist movement, it was used chiefly as the name of a doctrine, or body of doctrines, and thus tended to be applied very widely to all social theories which stressed the need for collective political or economic action in opposition to the dominant individualist doctrines. The so-called "Socialism of the Chair," which had a vogue in Germany during the second quarter of the 19th century, was called "Socialism" mainly in the broad philosophical sense; and "Christian Socialism," in many of its manifestations, is Socialist only in the sense that it stresses, in opposition to individualism, the corporate nature of society and the need for social solidarity based on the fatherhood of God and the brotherhood of man. In more recent times, as distinctively Socialist ideas have become embodied in a number of organized movements, national and international, the tendency has been to think of Socialism more as a movement than as a doctrine, and to sum it up rather as what the Socialists want than as a definite body of theoretical dogma. For there exists no canon of Socialist doctrines on which all Socialists would agree. Karl Marx came nearest to providing such a canon in his formulation of "Scientific Socialism" as contrasted with the "Utopianism" of his predecessors. But, while most of the Continental Socialist parties profess to base their policy on Marxism, and employ Marxian phrases and ideas for its expression, there are many different interpretations of Marxism, and, in any case, the fundamental doctrines of Marx himself form rather a philosophy of history and a critique of capitalist industrialism and orthodox political economy than a positive policy for Socialism to-day. Moreover, there are many Socialists, including the majority in Great Britain, who do not profess to be Marxists at all.

From the Marxian standpoint, Socialism is the struggle of the working class, or proletariat, to free itself from the domination of capitalism, and establish a new classless society collectively controlled in the interest of the whole people. Marx nowhere formulates clearly either the nature of this new society or the detailed steps by which it is to be approached. He is far more interested in the struggle than in the goal to which it tends; and any attempt to forecast in detail the structure of a Socialist community would have seemed to him mere Utopianism. The parties based on Marxism follow the master's lead, and tend to define their policy in terms rather of the class-struggle between capitalists and labourers than of the positive ends sought in the struggle. The non-Marxist British Socialists, for their part, have usually been more concerned with the early stages in a gradual evolution towards Socialism than with the completed process. Only the Guild Socialists, of modern Socialist groups, have attempted to forecast in detail the structure of the new society they are seeking; and even their attempt is confined, in the main, to an outline of the structure of industry under a system of "workers' control" or "industrial self-government."

We have, then, in attempting to make more precise our definition of Socialism, to avoid relating it in our minds to any Utopian picture of the future. We can say that Socialists seek the common ownership and collective control of the means of production and exchange; but we cannot say that this involves either the "nationalization" of all industries or some particular way of managing them. There are many possible forms of common ownership—nationally by the State, locally by municipalities or similar bodies, and, locally or nationally, by quasi-public trusts, guilds or corporations acting on behalf of the public. There are also many possible forms of administration—directly by State or municipal departments, by specially-constituted boards or commissions of experts, or by representative bodies of producers or consumers, or of both. All these forms of ownership and administration have had advocates among Socialists, and many Socialist plans embody features from several of them, or allow for diversity of experiment in different cases. Nor can it even be assumed that Socialists wish all the means of production to be publicly owned. If the vital and basic industries and services were under public control, many Socialists would be ready to leave smaller enterprises largely in private hands.

It is, however, clear that, whatever might be the precise form of social organization desired, all Socialists would wish the vital aspects of the economic life of society to be brought under collective control. This applies to production and distribution alike. One aspect of Socialism is the collective control of the productive forces; another, certainly no less important, is the collective control of the distribution of the social income. For, fundamentally, the object of the control of production is the abolition of poverty, unemployment and social classes, and the sharing out of all the wealth that the community is able to produce on more equitable lines than capitalism allows.

All Socialists would agree that a more equitable distribution of the social income means a less unequal distribution. But, while some regard absolute equality of income as the only Socialist solution of the problem, others reject this view, and seek only to ensure an adequate minimum for all, and to limit within reasonable bounds the degree of inequality above this minimum. "To each according to his needs" has been a frequent cry among Socialists as well as Anarchists, and many Socialists have regarded complete "Communism," in the sense of unlimited free distribution, as desirable for as many goods as can be produced in the necessary abundance. William Morris's Socialist Utopia, *News from Nowhere,* is purely Communistic in this sense of the term. But the conception of distribution according to need has commonly, as a practical policy, been either re-stated as a conception of complete equality, on the ground that equality is, in face of the limitation of human resources, the nearest workable equivalent, or limited to a demand for an assured minimum standard of living. A desire to lessen inequality of incomes, and to use the State and taxation as the means of achieving this, is all that can be safely assumed as the common doctrine of all schools of Socialists.

The Socialist desire for a nearer approach to equality is not, however, confined to the region of incomes. It implies also the desire both for equality of political rights and for equality of economic and social status. Political democracy, Socialists often contend, can never be made a reality as long as gross inequalities of wealth and status are allowed to persist. Wealth, for example, gives its possessor the means of exerting an exceptional influence on political opinion, and often neutralizes the effects of formally democratic political institutions. Socialists, therefore, stand for political democracy completed and made workable by the abolition of class distinctions and of dangerous inequalities of wealth. This does not imply that they believe the means of transition to Socialism must conform to orthodox democratic ideas; for the Communists, for example, repudiate existing political democracy as a sham, and insist that Socialism can be introduced only by a revolutionary "dictatorship of the proletariat." This view is repudiated by the majority of Socialists outside Russia; and the Socialist parties usually attempt to work towards Socialism by using the methods of parliamentary democracy. This, however, is a matter of expediency rather than of principle; whereas all Socialists, including Communists, believe that Socialism, once securely established, will organize its collective control of society on democratic lines. The "dictatorship" of the Communists is regarded only as a necessary instrument of the transition to a really democratic system.

The differences of view among Socialists, and the difficulty of formulating any precise definition of the policy of Socialism, do not mean that Socialism does not constitute a clearly recognizable movement and body of tendencies in economic and social policy. It is indeed sometimes difficult to say whether a particular organization can properly be described as Socialist or not. The British Labour Party, for example, founded originally in 1900 as the Labour Representation Committee, on the basis of an alliance between the Socialist societies and the trade unions, had at the outset no definite policy, and only adopted Socialist views gradually. There was, in its early years, a dispute at the International Socialist Conference on the question whether its delegates ought to be admitted. Even to-day, though its policy is, in general,

clearly Socialist, it is quite possible for non-Socialists who agree with its immediate programme to be actively associated with it. The Continental parties, having for the most part a definitely Marxian basis, are, in words, far more fully committed to Socialism; but it does not appear that the verbal difference exerts any important influence on their policy. Broadly speaking, the political Labour movement is everywhere Socialist, in that its declared policy conforms with the definition given at the beginning of this article. *Labour and the New Social Order,* the famous manifesto issued by the British Labour Party in 1918, is perhaps the best and clearest short exposition of moderate and evolutionary Socialist policy that has yet been produced.

Origin of the Name.—The words Socialism and Socialist appear to have come into use at nearly the same time in both England and France about 1830. They were employed to describe, in Great Britain, the teachings and the followers of Robert Owen, with his "social system," and, in France, those of Fourier and Saint Simon. Thereafter, the words remained in use, but were often very loosely applied. Survivals of their loose application are to be seen in the names of certain modern political parties, such as the Christian Socialists in Austria and the Socialist-Radicals in France. Neither of these parties is Socialist at all in the modern sense of the word as defined above.

The name acquired a more precise denotation with the growth of Socialist parties in various countries. But the movements out of which these parties grew were more often called "Communist" in their earlier stages. The "Communist Manifesto," drafted by Karl Marx and Friedrich Engels for the Communist League and issued in the "year of revolutions," 1848, is generally regarded as the starting point of modern Socialism. Its second stage is marked by the creation of the International Working Men's Association in 1864, under Marx's leadership (*see* INTERNATIONAL); but the name "Socialism" was not generally applied until Socialist and Social Democratic parties were organized in France, Germany and elsewhere on a permanent basis (German Social Democratic Labour Party 1869—reformed 1875). The International Socialist Bureau, linking up these parties, was not founded until 1900, though a number of international Labour and Socialist Congresses had been held at earlier dates.

The denotation of the Socialist movement thus gradually became plain during the last quarter of the 19th century. The connotation of the word socialism began to be more clearly defined at the same time. Though Marxism never commanded the allegiance of all who called themselves "Socialists," it was above all Marx who first gave Socialism as a body of economic and political doctrine a definite form. This process, begun in the *Communist Manifesto* of 1848, was carried on in Marx's later writings and manifestoes, and above all in the first volume of *Das Kapital* (1867). Marx and his followers distinguished their doctrines, as "Scientific Socialism," from the Utopian Socialism which had gone before. Owen, Fourier, Saint Simon and other Socialist forerunners they regarded as unscientific Utopia-builders, whereas Marxism professed to base itself on a scientific explanation of the movements of history. The materialist conception of history, working itself out in a succession of class struggles, became the scientific basis of the new Socialist movement which arose under Marxian inspiration. The programmes and policies of the new Socialist parties of the '70s and '80s were conceived in Marxist terms; and for a time it seemed as if Marxism and Socialism could be regarded as practically identical. (For an account of Marx's doctrines and activities, *see* the article MARX, KARL.)

Practically, the most important outcome of Marxian Socialism was the close identification of Socialism with the working-class movement. Basing his theory of Socialism upon the class struggle, Marx necessarily regarded the working-class, or proletariat, as the instrument by which Socialism would be created. The task of the Socialists was, therefore, the political and economic organization of the working-class, and its education in class-consciousness and collective action. The close connection between Socialism and such working-class movements as trade unionism, regarded as the instrument of the class struggle in the industrial field, arises naturally out of the Marxist view of Socialism. Modern Socialist propaganda has been, above all, an attempt to bring the organized workers over to a faith in Socialism, to permeate the trade unions and other working-class bodies with Socialist ideas, and to create Labour parties, as in Great Britain, on a Socialist basis and with a Socialist policy. Modern Socialism is more than a working-class movement, and many are Socialists who are not "proletarians," or workers in the ordinary sense of the word. But everywhere the Socialist movement is predominantly working-class, and acts in close conjunction with trade unions and other working-class bodies.

Early History.—Although the words Socialism and Socialist came into use only in the first half of the 19th century, many of the ideas now associated with Socialism have a far longer history, and many earlier writers and reformers are nowadays often called Socialists. Socialist elements, for example, are discerned in the Mosaic law and in the writings of Amos, Hosea and Isaiah, as well as in the so-called "Socialism of the gospels," on which many mediaeval Communist doctrines were explicitly based. The ordered and stratified social system of Plato's *Republic* is often called "Socialist," and clearly is so if Socialism is only the antithesis of individualism and *laissez-faire*. The idea of an ordered society based on community of goods appears again and again in the history of political and religious speculation, from the days of the ancient Greeks through Roman and mediaeval times to the modern world. It is possible to trace many communistic elements in the social institutions of primitive peoples, and there have been theories which represented the rise of individualism and private property as a fall of man from an ideal primitive communism.

As we come nearer modern times, there are clearly large elements of Socialism and Communism in such works as More's *Utopia* and Campanella's *City of the Sun;* and in the 17th and 18th centuries, though Utopia-making went out of fashion, doctrines resembling modern Socialism in one or another respect were abundant. Gerrard Winstanley and the Diggers, Peter Chamberlin, John Bellers and James Harrington, all in their several ways emphasized the vital influence of the economic organization on the political and social condition of the people, and sought to bring economic institutions under some sort of collective control. And, in 18th century France, before the Revolution, while Rousseau attacked the influence of inequality on social institutions and stressed the authority of the State as the embodiment of the general will, writers such as Mably and Morelly worked out social systems based on communism and collective organization of the economic forces of society. On the morrow of the Revolution, the *Conspiration des Egaux* of Gracchus Babeuf and his followers struck the first definitely proletarian note in modern revolutionary history, and influenced not only the French Socialists of the next generation, but also, through James Bronterre O'Brien, the English Chartists.

It is not, however, very profitable, at any rate in this brief treatment, to delve deeply into the history of those doctrines and movements which can be regarded as, in this or that respect, anticipations of modern Socialism. The Socialism with which it is necessary to deal here owes its rise to the growth of large-scale production based on machinery and steam-power. It made its appearance when the changes in methods of production and transport, usually described as the "Industrial Revolution," had created the modern working-class or "proletariat," and had caused that class to organize in some degree for common protection against the evil effects of the new industrial conditions. There was plenty of misery among the workers long before the "Industrial Revolution," and plenty of attempts to make a stand against it were made. But continuous working-class organization, and Socialist doctrines aiming at the collective control of the means of production in the interests of the workers, alike date from the rise of the factory system, which not only subjected them to an unfamiliar and bitterly resented discipline, but also, by massing them together in factories and industrial towns, made agitation among them easier, and combination the natural means of seeking redress.

Socialism of this type naturally arose first in Great Britain, which, in the latter part of the 18th century, took the lead in the transformation of economic processes by the application of

machinery and steam-power. The real foundations of modern Socialism were laid in Great Britain during the first three decades of the 19th century. The Radical and revolutionary writers and leaders of the later 18th century in Great Britain can, for the most part, not be called Socialists. Ogilvie and Tom Paine were Radical land reformers; and Paine put forward advanced Radical views on taxation and the development of social services under the State. But neither was a Socialist in any real sense; and even Thomas Spence, whose followers, the "Spencean Philanthropists," are often regarded as the first English Socialists, was an advocate of land nationalization hardly conscious of the problems presented by the new industrialism. William Godwin, whose *Political Justice* was the bible of intellectual Radicalism at the end of the 18th century, was far more Anarchist than Socialist, and barely discussed the organization of industry.

This was natural; for it was not until the end of the Napoleonic Wars that there was opportunity for an articulate working-class movement to develop in Great Britain, or that the problems of the new industrial system forced themselves on public attention. British Socialism, as a theoretical movement, was born in the decade which followed the battle of Waterloo; and this decade saw also the beginnings of effective political and industrial combination among the workers in the rapidly-growing factory districts.

Owenism.—Robert Owen, the great and successful textile employer of New Lanark, was the first to formulate the doctrine of Socialism in comprehensive form, and to his followers the name "Socialists" was first applied, though he himself commonly spoke of his scheme as "the social system," or "the rational system for the organization of society," or, sometimes, as "the New Moral World." Owen first appeared as a Socialist in the years immediately after 1815. Known earlier as a great educational and factory reformer, he was led by the distress and unemployment which followed the peace to formulate and propose to the Government a scheme for the productive employment of the poor in "villages of co-operation." Rejected by the Government and by the rich, to whom Owen next appealed, this scheme was taken up by the workers, and Owenite societies, with a predominantly working-class membership, were formed all over the country. The growing trade unions were largely captured by the new doctrines, and in 1830 and the following years Owen found himself at the head of a great working-class movement seeking to establish Socialism by means of industrial organization and action. Then, in 1834, the Grand National Consolidated Trades Union, attacked by employers and Government alike, went to pieces, and Owenism shrank up into small propagandist groups, whose greatest achievement was the creation of the Co-operative movement. Socialism, as a doctrine commanding a wide body of adherents, died away in Great Britain, and had to await, for its revival, the coming of Marxism as an international force among the workers.

Robert Owen's Socialism did not begin as, and was never in its creator's mind, a class movement. That was, in large part, why Marx called it "Utopian." Owen became a working-class leader, not because he wished to appeal to one class alone, but because only the workers followed his leadership. He was essentially a philanthropic reformer, acutely conscious of the evils of the industrialism by which he had made his wealth, and confident that these evils could be prevented, and the new productive forces turned to the benefit of mankind, by proper organization and control. He believed the evils of industrialism to be due mainly to two causes—competition and bad education. For competition, which forced down the standard of life and set man against man, he desired to substitute a co-operative control of industry, in order that production might everywhere be maximized in the interests of all, and the product distributed among all according to need. But he believed that men would only give up competition and live co-operatively if, in childhood, they were educated in the right social ideas. His Socialism was, therefore, founded on education, and he was out of his element when he was called upon to lead a great working-class movement which sought to establish Socialism and co-operation by mass action without changing the hearts of men by education. But Owen was also an extraordinary optimist, able to believe that the hearts of men in the mass could be suddenly changed by the proclamation of his new doctrines. In this spirit, he accepted the rôle of working-class leader; but the failure of his great trades union, instead of discouraging him, merely sent him back to spend the rest of his life, undismayed, in educational propaganda on behalf of his ideas.

The two decades which saw the rise and fall of Owenite Socialism as a mass movement were fertile in the growth of Socialist theories. Writers such as Thomas Hodgskin (*Labour Defended*, 1825), attacked the orthodox economists, and drew Socialist deductions from Ricardo's subsistence theory of wages; while William Thompson (*Distribution of Wealth*, 1824), combined constructive Owenite Socialism with destructive criticism of the Ricardians. J. F. Bray, Charles Hall, John Minter Morgan, Piercy Ravenstone, T. R. Edmunds, John Gray and George Mudie are also among the writers who, during these decades, formulated, on broadly Socialist lines, a powerful indictment of capitalist society, reinforced by Thomas Carlyle's denunciation of the Manchester school, and by the Radical political writings of William Cobbett and a host of working-class journalists. Apart from Owen, no writer at this stage designed a constructive Socialist scheme; but the movements of working-class Radicalism, from the Spenceans of 1816 to the Chartists of the '30s and '40s, were strongly imbued with anti-capitalist economic doctrines. Engels, and to a less extent Marx, were in close touch with the Chartists, and there is a direct line of succession from the Chartist and kindred movements of the '40s to the Marxian agitation of 1864 and the following years.

French Socialism.—Meanwhile, in France, Socialism had been pursuing an independent course. Count Henri de Saint-Simon (1760–1825) began to develop his Socialist views about the same time as Owen in Great Britain, while François Marie Charles Fourier (1772–1837), although he outlined his Socialist scheme as early as 1808, had little influence till a good deal later. Both these writers belong, far more than Owen, to the category of Utopian Socialists; for neither had at any stage the same connection as Owen with the organized working-class movement, for which, in France, the time was not yet ripe. Saint-Simon's scheme was, in essence, a plan for the ordered government of society by economic experts. Out of it arose, after his death, a powerful school of thinkers, including Bazard and Enfantin. It greatly influenced Comte, and left its most abiding mark in the development of Positivism, rather than on Socialist thought. Fourier's plan of *phalanstères* was far more like Owen's scheme for Villages of Co-operation; but it, too, was developed rather as an abstract proposal for the perfecting of human institutions than as an attempt to deal with the positive evils of contemporary industrial society. Both the Saint-Simonians and the Fourierists founded societies in Great Britain; and these were found now disputing and now collaborating with the Owenites.

French Socialism entered on a new phase after the Revolution of 1830. Considérant carried on the tradition of Fourier. Louis Auguste Blanqui began his long career of insurrectionary organization. Louis Blanc, in 1840, published his famous tract, *L'Organisation du Travail.* P. J. Proudhon, in the same year, startled Paris with his first important work, *Qu'est ce que la Propriété?* The stage was being set for the French Revolution of 1848, in which, for the first time, the gulf between Socialists and ordinary Republicans was made clearly manifest, and, outside England, a proletarian movement made its distinctive appearance.

Of these leaders, Blanqui, who spent the greater part of his life in prison under successive French Governments, counts, not as a theorist, but as the most persistent revolutionary organizer in Socialist history. His was largely the work that went to the making of the Paris Commune of 1871; and it was the misfortune of the Commune that the Versailles Government had him safe in prison before it was proclaimed. Proudhon counts less as a Socialist than as a theorist of Anarchism and a powerful influence on the development of French trade union and Co-operative thought. Louis Blanc, with his scheme of national workshops (*q.v.*), belongs more properly to the Socialist tradition. Like Owen, he attacked the vices of competition, and urged that the State should eliminate the capitalist by establishing workshops of its own, to be

handed over subsequently to the workers to control. Blanc was a member of the revolutionary Government of 1848, but the workshops started by that Government were a mere travesty of his scheme, and were deliberately crushed by the anti-Socialist majority in the Government. His ideas, and those of Buchez, helped to inspire the Christian Socialists in England, where Charles Kingsley contrasted Blanc's plan for the organization of labour favourably with the purely political demand of the Chartists.

Marxism.—The French Socialism of 1848 was crushed out in the series of events which led up to the *Coup d' état* and the proclamation of the Second Empire. English Owenism had already shrunk up into a tiny sect, after giving birth to the co-operative movement, which speedily lost its original Socialist policy. Chartism was already on the way to dissolution before the failure of the demonstrations and petition of 1848. The Communist League, the international body with which Marx was associated, disappeared in the wave of reaction which spread over Europe as one by one the revolutionary movements of 1848 were liquidated. Socialism remained alive only as the creed of isolated sects, often of exiles. It did not again grow to any considerable stature until the coming, in 1864, of Karl Marx's International Working Men's Association, commonly known as the "First International."

The First International had its headquarters in England throughout its earlier and influential years of life. But this does not mean that Socialism was strong in Great Britain. After the collapse of Chartism, the British working-class movement played for some time little part in politics, but devoted itself to the building up on moderate lines of strong trade unions and co-operative societies. In the early '60s, the leaders of the movement began a vigorous agitation for the extension of the franchise and the fuller legal recognition of trade union rights. The country was very prosperous, and, aided by the prosperity, working-class organizations grew apace. Marx was able to enlist the sympathies of the British leaders for the task of economic and political agitation among the workers abroad; but they were never brought to accept his Socialist ideas, or made really conscious of the revolutionary policy for which the First International stood on the Continent.

Gradually, in the later '60s, Marx and his colleagues built up the International, in one country after another, into a powerful organization of which Governments became deeply afraid. Especially did it take root in Germany, where it gave birth to the Social Democratic Labour Party, headed by Marx's followers, August Bebel and Wilhelm Liebknecht. Here Ferdinand Lassalle (1825–1864) had founded his General Workmen's Union in 1863, and after his death the division between his followers and those of Marx persisted until 1875, when the two parties united on the basis of the famous "Gotha Programme," strongly criticized by Marx himself for its concessions to the Lassallian standpoint. In France, the Marxists contended for influence with the secret societies organized by Blanqui and his colleague, Barbès, and with the followers of Proudhon; but they played, in Blanqui's absence in prison, the leading part in the ill-starred Paris Commune of 1871. The defeat of the Commune, and the savage repression which followed it, wiped out French Socialism, for the time, as an effective force. But there was soon a revival; and the *Parti Ouvrier* founded by Jules Guesde in 1875–76 was a strictly Marxist body. French Socialism, however, long continued to be torn asunder by conflicting tendencies, and especially by the strength of Proudhonist and Anarchist influences, which were dominant in the trade unions and prevented any effective alliance between the political and industrial forces. Not until 1905 was unity achieved even among the rival political groups; and even then the hostility between the Socialists and the trade unions remained unappeased.

In Italy and Russia, Marxism had to contend with the powerful influence of Michael Bakunin, which eventually helped to tear the First International asunder. Bakunin founded, in 1868, an International Social Democratic Alliance, which was rather Anarchist than Socialist in doctrine. Temporary compromises were patched up; but in 1872 at the Hague conference the quarrel again reached breaking point. Bakunin and his followers were expelled by the Marxists from the First International, and, on Marx's motion, the seat of the International was moved from London to New York, where it expired four years later. Its period of influence had virtually ended with the fall of the Paris Commune in 1871, which had scared away most of its more moderate supporters. But it left its permanent mark on Europe, by laying the foundation for the national Socialist parties which sprang up during the following decade in almost every country.

National Movements.—After the fall of the First International, the history of Socialism becomes a history mainly of separate national movements. Germany, where Marx's doctrines had taken the deepest root, supplied the main driving force. From 1878 to Bismarck's fall in 1890, Socialism in Germany was proscribed by special laws, and the agitation had to be carried on mainly from abroad. It grew fast none the less, and, when the German Social Democratic Party was again able to appear in the open, in 1891, the Erfurt Programme of that year was a purely Marxist document. Thereafter the German Social Democrats rapidly increased in parliamentary power. With this growth went a gradual evolution of doctrines within the party, as the revolutionary ideas of Marxism were challenged by "revisionists" desirous of working less for a sudden overthrow than for a gradual transformation of capitalist society. The "revisionists," headed by Eduard Bernstein, who had been greatly influenced by British labour developments, were officially defeated in 1903 at the party congress; but in fact their doctrines permeated the majority of the party, making it less and less revolutionary in its real policy, even while it scrupulously preserved the Marxist phraseology of the preceding generation.

Meanwhile, in Great Britain, the great outburst of labour and trade union activity in the '60s and early '70s had been brought to an end by the serious trade slump of the later '70s. Between 1864 and 1874, it looked as if the British trade union leaders were well on the way to create a separate Labour Party. But after the slump, Labour, seriously weakened, fell back on a dependant alliance with the Liberal Party. Such working-class candidates as entered parliament sat there as Liberals, and Socialism, never strong, was wiped out as an effective influence.

It returned, under Marxist inspiration, in the early '80s. In 1881 Henry Mayers Hyndman, previously a well-known Radical journalist, founded, the Democratic Federation, which speedily accepted Marxian ideas, and, in 1884, adopted the name "Social Democratic Federation" and a complete Socialist programme. In the same year, a split within this body led to the creation of the Socialist League, headed by the famous poet, William Morris, and inspired rather by anarchist-syndicalist ideas in opposition to the purely political Marxism of the S.D.F. These two bodies conducted a widespread agitation during the severe trade slump which culminated in 1886, and were largely responsible for the outburst of aggressive trade unionism among the less skilled workers which found its chief expression in the great dock strike of 1889.

Marxism, however, was not destined at this stage to capture the British Labour movement. Already, in the '80s, Sidney Webb and other leaders of the Fabian Society were developing a moderate and evolutionary Socialism which based its economics rather on Jevons and John Stuart Mill than on Karl Marx, and aimed rather at permeating the existing parties with socialistic ideas than at creating a definitely Socialist party. *Fabian Essays* (1889) gave expression to this new doctrine; and this book was followed up with a wealth of well-written tracts advocating various forms of constructive semi-Socialist legislation.

At the same time, the younger trade unionists, largely stirred into action by the Marxist S.D.F., were beginning to repudiate its doctrine, and to aim at the creation, not of an avowedly Socialist party, but of a more moderate Labour Party, into which there would be more hope of drawing the trade unions and the main body of the workers. James Keir Hardie, a young Scottish miner and a convert from Liberalism, became the leading exponent of this non-dogmatic Socialism, which eschewed theories and based itself and its appeal to the workers on an evolutionary programme of social reform. The result was the creation, in 1893, of the Independent Labour Party, as a rallying point for the "New

Unionists" and other exponents of Labour-Socialism. One of the main objects of the new body was to draw the trade unions as organized bodies, into politics, and so to get behind it the main body of workers. This aim was largely achieved when, in 1899, the Trades Union Congress at last voted in favour of creating an independent working-class party based on a trade-union-Socialist alliance. The Labour Representation Committee, which in 1906 became the Labour Party and entered politics as an effective force, was accordingly created in 1900, with the I.L.P. as its chief driving power, and the Fabians as its counsellors on questions of practical policy. These developments, as we have seen, reacted on German Socialism, and caused Social Democracy in Germany, despite the nominal defeat of Bernstein's "revisionist" party, largely to re-model its tactics on non-revolutionary lines.

Indeed, in the early years of the 20th century, as Socialism became in one country after another a powerful parliamentary force, there was a notable modification of its revolutionary attitude. In practice, Socialist parties which had won a substantial representation in parliament found themselves growingly impelled to work for the improvement of current legislation on social questions, and to appeal to the electorate, not as revolutionaries, but as constitutional reformers seeking a peaceful transformation of the social system. Only where, as in Russia, Socialism was still outlawed, and unveiled autocracy remained in being, did Marxian ideas survive in their original simplicity.

On the eve of the World War, almost every developed country possessed a powerful Socialist or Labour Party, with numerous representatives in parliament; but in no case, except Australia, had the Labour Party achieved a clear majority. In Great Britain, indeed, political development had lagged behind; for the Labour Party had only become properly organized in 1906, and was, in 1914, still but a small group in comparison with the French or German Socialists. It was, moreover, in the years immediately preceding the war, subjected to an increasing amount of criticism for its compromising tactics and its virtual alliance with Liberalism in the House of Commons. These were the years during which a great wave of labour unrest spread over Europe, and new doctrines of Syndicalism and Industrial Unionism, originating in France and America, sought to speed up the pace of economic evolution by resort to industrial action. There were great strikes in England, and new conceptions of Socialism began to make headway. In particular, the idea of the control of industry by the workers through their industrial organizations was widely preached, and traditional conceptions of Socialism were attacked as making for bureaucracy and denying the democratic demand for self-government in the industrial as well as in the political sphere. In Great Britain, Guild Socialism made rapid headway as the expression of this demand for "workers' control."

Both the prevalent industrial unrest and the re-statement of Socialist doctrines were checked for the time by the outbreak of war in 1914. The issues of war sharply divided the Socialist forces. In every belligerent country some Socialists supported and some opposed the participation of their Governments. In the leading countries, except Italy and Russia, the majority supported participation; but in each case a powerful minority took the opposite view, and the Socialist movement ran considerable risk of dissolution in consequence of the cleavage. In Great Britain, for example, while the Labour Party officially supported the war, the Independent Labour Party, which was one of its constituent bodies, opposed it. In Germany, the Social Democratic Party split into two rival bodies, the larger supporting the war and the smaller hostile; and in France an almost similar situation arose, though a positive split was, for the time, averted.

The Russian Revolution.—This was the situation when, in 1917, Russia broke out into open revolution. The Russian Socialist movement, persecuted and proscribed by Czardom, had been, throughout its career, revolutionary by the necessity of its condition. It was, however, sharply divided into rival parties. The largest, the Social Revolutionary Party, was active mainly among the peasants, and was inclined to terrorist tactics and out of touch with West European Socialism. The Social Democratic Party, formed on a Marxian basis towards the end of the 19th century, had divided, in 1904, into two rival groups—the Mensheviks aiming at collaboration with the middle-class parties in the establishment of a constitutional republic as a step to Socialism, and the Bolsheviks, who stood for a complete transformation to Socialism by means of a revolution to be carried through by the "dictatorship of the proletariat." Both parties appealed to Marx as their master, the Mensheviks interpreting Marxism in accordance with the revised practice of the West European Social Democratic Parties, while the Bolsheviks adhered to the revolutionary ideas advocated in the Communist Manifesto of 1848 and the publications of the International Working Men's Association.

The first Russian Revolution of 1917, carried through with the collaboration of Mensheviks, Social Revolutionaries and middle-class Liberals, commanded the universal support of Socialists in all countries. The second, by which the Bolsheviks, aided by a section of the Social Revolutionaries, seized power and proclaimed the "dictatorship of the proletariat," sharply divided European Socialism. The division was accentuated when the Bolsheviks, having established themselves in power, proclaimed themselves the Communist Party, established a new Communist International, and set out to foster a world revolution on principles which they professed to derive directly from Marx's writings, and especially from the Communist manifesto of 1848. The new Communist leaders then denounced the Social Democrats as "social traitors," guilty of the sin of repudiating Marxism and collaborating with the bourgeoisie for the maintenance of capitalism; and the Social Democrats retorted by attacking the Communists as tyrants who had crushed out liberty and democracy in Russia, and imposed their will by force on the mass of the common people.

European Socialism was rent asunder by this conflict, which was far more severe on the Continent than in Great Britain. In Germany, the Social Democrats maintained their position despite the rise of a powerful Communist Party. In France, the majority of the Socialist Party actually went over to Communism, and the Socialist Party was reconstituted as a minority group, which has since electorally regained the upper hand. The sharp division of Italian Socialism into Communist, semi-Communist and anti-Communist factions greatly helped to prepare the way for the triumph of Fascism, which has now driven what remains of Socialism in Italy completely underground. The leaders of the anti-Bolshevik Socialist bodies in Russia, driven from their own country, helped to embitter the conflict elsewhere. European Socialism was divided into two warring camps, organized respectively in the Labour and Socialist International (created to succeed the pre-war International Socialist Bureau as the organ of constitutional Socialist and Labour parties), and the Third, or Communist, International, organized from Russia as the centre for the propaganda of world-revolution.

In Great Britain, Communism has remained too weak to be more than a nuisance to the Labour Party, and a useful bogey to be held up by anti-Socialists in order to scare the electorate. The trade union basis of the British Labour Party makes a split far harder to bring about than it is where Socialist parties are organized apart from the trade unions; and in any case the following of the Communists in Great Britain has remained too small for them to become an effective political force. Nevertheless, here as elsewhere, the Russian Revolution of 1917 has exerted a powerful influence on Socialist opinion, combining with the evolution of economic forces to undermine belief in the stability of the present economic and political order, and giving a stimulus to aggressive trade union action, which found its chief expression in the great strikes of the years following the war, and culminated in the abortive "General Strike" of 1926. On the whole, of late the influence of Communism in the world has declined, as one country after another has to some extent settled down, and the possibility of world-revolution has receded. But it remains a powerful movement, now in most countries sharply distinct from orthodox Socialism, which continues, in despite of it, to move slowly forward towards the constitutional conquest of political power. Already a number of the leading European countries have had, for short periods, Socialist or Labour Governments, which have

held office, by temporary sufferance of other parties or by virtue of their divisions. Great Britain had such a Government in 1924; Sweden has had more than one; Germany has, in 1928, a Socialist chancellor. It is not likely to be long before, in more than one European country, a Socialist Government is able to take office with a clear parliamentary majority behind it.

In this growth of world Socialism, the United States significantly lag behind. The American Socialist Party is still politically an impotent group, and the trade unions still reject all attempts to draw them into organized political activity on party lines. American economic conditions are still markedly individualistic, and American wages and opportunities, for the minority of skilled workers, good enough to hold back any strong development of a Socialist movement. Europe, with its far more homogenous working class and its far more limited ability to give the workman, under capitalism, an opportunity of bettering his position, is in a different situation, and all over Europe, except in the areas temporarily dominated by Fascism and analogous movements, Socialism continues to gain ground.

Socialist Policy.—The distinction between Socialism, as represented by the various Socialist and Labour Parties of Europe and the New World, and Communism, as represented by the Russians and the minority groups in other countries, is one of tactics and strategy rather than of objective. Communism is indeed only Socialism pursued by revolutionary means and making its revolutionary method a canon of faith. Communists, like other Socialists, believe in the collective control and ownership of the vital means of production, and seek to achieve, through State action, the co-ordinated control of the economic forces of society. They differ from other Socialists in believing that this control can be secured, and its use in the interests of the workers ensured, only by revolutionary action leading to the "dictatorship of the proletariat" and the creation of a new proletarian State as the instrument of change. The existing States and parliaments, which the orthodox Socialists seek to capture and use as the agents of social transformation, the Communists denounce as purely capitalist institutions, which must be forcibly overthrown before the constructive work of Socialism can even begin. This doctrine, derived from Marx's Communist manifesto of 1848, is forcibly developed by Lenin in his book, *The State and Revolution* (1917), which gives the clearest account of the underlying political theories of the Communist Party. It follows from this view that the orthodox Socialists, who seek to use the existing institutions of State and parliament as the agents of gradual socialization, are regarded by Communists as the worst enemies of the workers, and denounced with a vigour far exceeding that which is meted out to the defenders of capitalist society.

Apart from this fundamental cleavage, Socialist ideas have undergone considerable transformation in recent years. All schools of Socialists still urge the transference of large-scale industry from private to public ownership; but mere State Socialism, or nationalization of the old type, is no longer a satisfying conception to Socialists of any school. Partly under Guild Socialist influence, and partly as a result of changes in the economic situation, all Socialist programmes now insist that the Socialist State must create special economic organs for the administration of industries under public control, and that the workers must be given some participation in the management of these services. For example, whereas before the war the British miners urged merely the nationalization of the coal industry by its transference to a State department, they now, in conjunction with the Labour Party, propose that it should be administered by a representative commission, and its policy co-ordinated with that of allied services by an expert power and transport board holding a largely independent position. Similarly, the French unions have put forward a new plan of "industrial nationalization," and the problem of "workers' control" has appeared largely in German schemes of socialization since the war. Guild Socialism, influential during and after the war in drawing attention to these problems of the control of industry, appears now to have made its distinctive contribution to Socialist thought and policy, and to have become merged in the general body of revised Socialist doctrine.

The Labour and Socialist International, 1928. Affiliated parties, with membership, voting strength, and representation in legislative bodies. (From the report of the Labour and Socialist International for 1928.)

*Membership includes affiliated trade unionists.
†Not at present affiliated to the Labour and Socialist International.
List of abbreviations: A.=Association, D.=Democratic, F.=Federation, I.=Independent, L.=Labour, R.=Revolutionary, S.=Social or Socialist, U.=Union or United, W.=Workers'.
Note. In addition, there are in most countries Communist parties affiliated to the Third International, and in some others Socialist or Labour Parties not belonging to either International.

The war and its aftermath have everywhere brought Socialism far nearer to the tests of practical experience and responsibility. Naturally, under these conditions, difficulties are more clearly seen, new problems come to the front, and differences previously latent tend to become more pronounced. It would take a bold

man to prophecy what will be the outcome of the present disputes between Communists and orthodox Socialists. It may be that the need for unity in pursuit of economic ends will, in the long run, reunite the warring factions in the European movement, and compel them to arrive at some basis of political agreement. For the existence of two contending working-class parties, each claiming to stand for Socialism, but seeking its end by distinctive means, has manifest disadvantages for the workers, especially if the quarrel is pushed into the industrial field, and results in a disruption of trade unionism in accordance with the political cleavage. This situation has not arisen in Great Britain in any grave form; but where it has arisen, as in France and Germany, it has weakened trade unionism even more seriously than political Socialism.

The forces making for unity are, first, that the ultimate aims proclaimed by the rival groups are largely the same, and secondly that Socialism is essentially not so much a theoretical plan of social reorganization as a class movement arising directly out of the economic divisions in society. It is an attempt to formulate, primarily for the working class, or proletariat, a policy designed to promote at once a larger and more balanced production and a more equal distribution of wealth, and to abolish class distinction based on inequalities of wealth or social opportunity, or on property laws which encourage the accumulation of the means of production in private hands. Its forms and policies differ from place to place, and vary with the movement of events and economic forces; but through all its changes it retains the fundamental character proclaimed for it in the Communist manifesto of 1848, as a movement based primarily on working-class organization and solidarity. By no means all Socialists, especially in Great Britain, call themselves Marxists; but to this extent, at least, modern Socialism bases itself firmly upon Marx's diagnosis of the social and economic problem.

Socialism has thus necessarily an economic foundation in the working-class movement; but it is important at the same time to realize that much of its driving force comes from its possession of a certain body of principles shared by Socialists of all schools, and scarcely subject to change with changes in the concrete political and economic situation.

Thus, all Socialists agree that the conduct of industry for private profit produces anti-social results, and challenge the view that the pursuit by each citizen of his private economic interests works out for the good of society on a whole. All Socialists, whatever their different views of the best forms of administration for Socialist undertakings, agree in holding that the major industries and services should pass under some form of co-ordinated public control, whether in the hands of the State, of local authorities, of self-governing guilds or co-operative societies, or of new forms of organization specially developed for the purpose. They agree in denouncing private control of the vital means of production, and in holding that both the form and the extent of the national output should be determined by considerations of social need.

Moreover, all Socialists insist that with a change in the control of industry will go a change in the motives which operate in the industrial system, and that the motive of public service, at present thwarted and inhibited by private capitalism, will be brought rapidly into play by the change from private to social ownership and control. Within this common ground there is room for wide differences of opinion and of practical policy; but, through all the changes and chances of the Socialistic movements of the world, these unifying conceptions give a common meaning to the vast variety of organizations and policies to which the term Socialist is habitually applied.

See the articles COMMUNISM, ANARCHISM, NATIONAL WORKSHOPS, and the chief biographies such as MARX, KARL; OWEN, ROBERT; FOURIER, F.M.C.; BLANQUI, L.A., etc.

BIBLIOGRAPHY.—The most useful historical book on the movement as a whole is H. W. Laidler, *History of Socialist Thought* (1927). *See* also T. Kirkup's *History of Socialism*, revised by E. R. Pease (1913), and W. Sombart's *Socialism and the Social Movement* (1909 —later revised editions available in German). For Great Britain, *see* Max Beer, *History of British Socialism* (1919–20); *Histoire du Socialisme en France* by Paul Louis; *German Social Democracy* by Bertrand Russell (1896) and *Geschichte der deutschen Sozial-Demokratie*, by Franz Mehring (1914), are among the numerous works dealing with Socialism in particular countries. For expositions of Socialist theory and policy, *see* J. Ramsay MacDonald, *Socialism, Critical and Constructive* (1921); S. and B. Webb, *A Constitution for the Socialist Commonwealth of Great Britain* (1920); Bertrand Russell, *Roads to Freedom* (1918); H. N. Brailsford, *Socialism for To-day* (1925); A. W. Humphrey, *The Modern Case for Socialism* (1928); G. Bernard Shaw, *The Intelligent Woman's Guide to Capitalism and Socialism* (1928). For critical accounts, *see* Hartley Withers, *The Case for Capitalism* (1920), and A. Shadwell, *The Breakdown of Socialism* (1926). Other useful books of historical interest, besides those mentioned in the text, include Robert Owen, *A New View of Society* and *A Report to the County of Lanark* (Everyman's Library, edit. G. D. H. Cole); C. E. Raven, *Christian Socialism* (1920), Shaw, Webb and others, *Fabian Essays on Socialism* (1889); William Morris and Belfort Bax, *Socialism, its Growth and Outcome* (1893); R. Blatchford, *Merrie England* (1895); E. Bernstein, *Evolutionary Socialism* (1909), H. G. Wells, *New Worlds for Old* (1908); G. D. H. Cole, *Self-Government in Industry* (1917). There are useful bibliographies in Laidler's *History of Socialist Thought*, mentioned above.

(G. D. H. C.)

SOCIALISM: PRINCIPLES AND OUTLOOK. Socialism, reduced to its simplest legal and practical expression, means the complete discarding of the institution of private property by transforming it into public property and the division of the resultant public income equally and indiscriminately among the entire population. Thus it reverses the policy of Capitalism, which means establishing private or "real" property to the utmost physically possible extent, and then leaving distribution of income to take care of itself. The change involves a complete moral *volte-face*. In Socialism, private property is anathema and equal distribution of income the first consideration. In Capitalism, private property is cardinal and distribution left to ensue from the play of free contract and selfish interest on that basis, no matter what anomalies it may present.

I.

Socialism never arises in the earlier phases of Capitalism, as, for instance, among the pioneers of civilization in a country where there is plenty of land available for private appropriation by the last comer. The distribution which results under such circumstances presents no wider departures from a rough equality than those made morally plausible by their association with exceptional energy and ability at the one extreme, and with obvious defects of mind and character or accidental hard luck at the other. This phase, however, does not last long under modern conditions. All the more favourable sites are soon privately appropriated, and the later comers (provided by immigration or the natural growth of the population), finding no eligible land to appropriate, are obliged to live by hiring it at a rent from its owners, transforming the latter into a *rentier* class enjoying unearned incomes, which increase continually with the growth of the population until the landed class becomes a money-lending or capitalist class also, capital being the name given to spare money. The resource of hiring land and spare money is open to those only who are sufficiently educated to keep accounts and manage businesses, most of whom spring from the proprietary class as younger sons. The rest have to live by being hired as labourers and artisans at weekly or daily wages; so that a rough division of society into an upper or proprietary class, a middle or employing and managing class, and a wage proletariat is produced. In this division the proprietary class is purely parasitic, consuming without producing. As the inexorable operation of the economic law of rent makes this class richer and richer as the population increases, its demand for domestic servants and for luxuries of all kinds creates parasitic enterprise and employment for the middle class and the proletariat, not only withdrawing masses of them from productive industry, but also fortifying itself politically by a great body of workers and employers who vote with the owners because they are as dependent on the owners' unearned incomes as the owners themselves.

Meanwhile, the competition of employers for custom, which leads to the production of a dozen articles to satisfy the demand for one, leads to disastrous crises of feverish over-production alternated with periods of bad trade ("booms" and "slumps"), making continuous employment of the proletariat impossible. When wages fall to a point at which saving also is impossible,

the unemployed have no means of subsistence except public relief during the slumps.

It is in this phase of capitalistic development, attained in Great Britain in the 19th century, that Socialism arises as a revolt against a distribution of wealth that has lost all its moral plausibility. Colossal wealth is associated with unproductiveness and sometimes with conspicuous worthlessness of character; and lifetimes of excessive toil beginning in early childhood leave the toiler so miserably poor that the only refuge left for old age is a general workhouse, purposely made repulsive to deter proletarians from resorting to it as long as they have strength enough left for the most poorly paid job in the labour market. The inequalities become monstrous: hard-working men get 4*s.* or 5*s.* a day (post-war rates) in full view of persons who get several thousands a day without any obligation to work at all, and even consider industrial work degrading. Such variations in income defy all attempts to relate them to variations in personal merit. Governments are forced to intervene and readjust distribution to some extent by confiscating larger and larger percentages of incomes derived from property (income tax, super-tax, and estate duties) and applying the proceeds to unemployment insurance and extensions of communal services, besides protecting the proletariat against the worst extremities of oppression by an elaborate factory code which takes the control of workshops and factories largely out of the hands of their proprietors, and makes it impossible for them to exact grossly excessive hours of labour from their employees, or to neglect their health, physical safety, and moral welfare with complete selfishness.

This confiscation of private property incomes for public purposes without any pretence of compensation, which is now proceeding on a scale inconceivable by Victorian ministers, has destroyed the integrity of private property and inheritance; and the success with which the confiscated capital has been applied to communal industries by the municipalities and the central Government, contrasted with the many failures and comparative costliness of capitalist industrial adventure, has shaken the superstition that private commercial management is always more effective and less corrupt than public management. In particular, the British attempt to depend on private industry for munitions during the World War of 1914–18 nearly led to defeat; and the substitution of national factories was so sensationally successful, and the post-war resumption of private enterprise, after a brief burst of illusory prosperity, was followed by so distressing a slump that the reversal of the relative efficiency prestige of Socialism and Capitalism was vigorously accelerated, leaving Capitalism unpopular and on the defensive, whilst confiscation of private capital for communal enterprise and nationalization of the big industries grew steadily in popularity in and out of Parliament.

This change in public opinion had already deeply penetrated the middle class because of the change for the worse in the position of the ordinary employer. He, in the 19th century, was admittedly master of the industrial and, after the reform of 1832, of the political situation. He dealt directly and even domineeringly with the proprietary class, from which he hired his land and capital either directly or through agents who were his servants and not his masters. But the sums required to set on foot and develop modern industrial schemes grew until they were out of reach of ordinary employers. The collection of money to be used as capital became a special business, conducted by professional promoters and financiers. These experts, though they had no direct contact with industry, became so indispensable to it that they are now virtually the masters of the ordinary routine employers. Meanwhile, the growth of joint-stock enterprise was substituting the employee-manager for the employer, and thus converting the old independent middle class into a proletariat and pressing it politically to the left.

With every increase in the magnitude of the capital sums required for starting or extending large industrial concerns comes the need for an increase in the ability demanded by their management; and this the financiers cannot supply: indeed, they bleed industry of middle class ability by attracting it into their own profession. Matters reach a point at which industrial management by the old-fashioned tradesman must be replaced by a professionally trained and educated bureaucracy; and as Capitalism does not provide such a bureaucracy the industries tend to get into difficulties as they grow by combination (amalgamation), and thus outgrow the capacity of the managers who were able to handle them as separate units.

This difficulty is increased by the hereditary element in business. An employer may bequeath the control of an industry involving the subsistence of thousands of workers, and requiring from its chief either great natural ability and energy or considerable scientific and political culture, to his eldest son without being challenged to prove his son's qualifications, though if he proposes to make his second son a doctor or a naval officer he is peremptorily informed by the government that only by undergoing an elaborate and prolonged training, and obtaining official certificates of qualification, can his son be permitted to assume such responsibilities. Under these circumstances, much of the management and control of industry gets divided between routine employers who do not really understand their own businesses, and financiers, who, having never entered a factory nor descended a mine shaft, do not understand any business except the business of collecting money to be used as capital and forcing it into industrial adventures at all hazards, the result being too often reckless and senseless over-capitalization, leading to bankruptcies (disguised as reconstructions) which reveal the most astonishing technical ignorance and economic blindness on the part of men in high repute as directors of huge industrial combinations, who draw large fees as the remuneration of a mystical ability which exists only in the imagination of the share-holders.

II.

All this steadily saps the business prestige of Capitalism. The loss of popular faith in it has gone much farther than the gain of any widespread or intelligent faith in Socialism. Consequently, the end of the first third of the 20th century finds the political situation in Europe confused and threatening: all the political parties diagnosing dangerous social disease, and most of them proposing disastrous remedies. National governments, no matter what ancient party slogans they raise, find themselves controlled by financiers who follow the slot of gigantic international usuries without any public aims and without any technical qualifications except their familiarity with a rule-of-thumb city routine quite inapplicable to public affairs, because it deals exclusively with stock exchange and banking categories of capital and credit. These, though valid in the money market when conducting exchanges of future incomes for spare ready money by the small minority of persons who have these luxuries to deal in, would vanish under pressure of any general political measure like—to take a perilously popular and plausible example—a levy on capital. Such a levy would produce a money market in which there were all sellers and no buyers, sending the Bank Rate up to infinity, breaking the banks, and bringing industry to a standstill by the transfer of all the cash available for wages to the national treasury. Unfortunately, the parliamentary proletarian parties understand this as little as their capitalist opponents. They clamour for taxation of capital; and the capitalists, instead of frankly admitting that capital as they reckon it is a phantom, and that the assumption that a person with an income of £5 a year represents to the State an immediately available asset of £100 ready money, though it may work well enough as between a handful of investors and spendthrifts in a stockbroker's office, is pure fiction when applied to a whole nation, ignorantly defend their imaginary resources as if they really existed, and thus confirm the proletariat in its delusion instead of educating it.

The financiers have their own *ignis fatuus,* which is that they can double the capital of the country, and thus give an immense stimulus to industrial development and production, by inflating the currency until prices rise to a point at which goods formerly marked £50 are marked £100, a measure which does nothing nationally but enable every debtor to cheat his creditor, and every insurance company and pension fund to reduce by half the

provision for which it has been paid. The history of inflation in Europe since the World War of 1914–18, and the resultant impoverishment of pensioners and officials with small fixed incomes, forces the middle classes to realise the appalling consequences of abandoning finance and industry to the direction of unskilled, politically ignorant, unpatriotic "practical business men."

Meanwhile, the mobility of capital leads to struggles for the possession of exploitable foreign territories ("places in the sun"), producing war on a scale which threatens not only civilization but human existence; for the old field combats between bodies of soldiers, from which women were shielded, are now replaced by attacks from the air on the civil population, in which women and men are slaughtered indiscriminately, making replacement of the killed impossible. The emotional reaction after such wars takes the form of acute disillusion, which further accelerates the moral revolt against capitalism without, unfortunately, producing any workable conception of an alternative. The proletarians are cynically sulky, no longer believing in the disinterestedness of those who appeal to them to make additional efforts and sacrifices to repair the waste of war. The moral mainspring of the private property system is broken; and it is the confiscations of unearned income, the extensions of municipal and national communism, above all the new subsidies in aid of wages extorted from governments by threats of nationally disastrous lock-outs and strikes, which induce the proletariat to continue operating the capitalist system now that the old compulsion to work by imposing starvation as the alternative, fundamental in Capitalism, has had to be discarded in its primitive ruthlessness. The worker who refuses to work can now quarter himself on public relief (which means finally on confiscated property income) to an extent formerly impossible.

Democracy, or votes for everybody, does not produce constructive solutions of social problems; nor does compulsory schooling help much. Unbounded hopes were based on each successive extension of the electoral franchise, culminating in the enfranchisement of women. These hopes have been disappointed, because the voters, male and female, being politically untrained and uneducated, have (*a*) no grasp of constructive measures, (*b*) loathe taxation as such, (*c*) dislike being governed at all, and (*d*) dread and resent any extension of official interference as an encroachment on their personal liberty. Compulsory schooling, far from enlightening them, inculcates the sacredness of private property, and stigmatizes a distributive state as criminal and disastrous, thereby continually renewing the old prejudices against Socialism, and making impossible a national education dogmatically inculcating as first principles the iniquity of private property, the paramount social importance of equality of income, and the criminality of idleness.

Consequently, in spite of disillusion with capitalism, and the growing menace of failing trade and falling currencies, our democratic parliamentary oppositions, faced with the fact that the only real remedy involves increased taxation, compulsory reorganization or frank nationalization of the bankrupt industries, and compulsory national service in civil as in military life for all classes, dare not confront their constituents with such proposals, knowing that on increased taxation alone they would lose their seats. To escape responsibility, they look to the suppression of parliamentary institutions by *coups d'état* and dictatorships, as in Italy, Spain, and Russia. This despair of parliamentary institutions is a striking novelty in the present century; but it has failed to awaken the democratic electorates to the fact that, having after a long struggle gained the power to govern, they have neither the knowledge nor the will to exercise it, and are in fact using their votes to keep government parochial when civilization is bursting the dikes of nationality in all directions.

A more effective resistance to property arises from the organization of the proletariat in trade unions to resist the effect of increase of population in cheapening labour and increasing its duration and severity. But Trade Unionism is itself a phase of Capitalism, inasmuch as it applies to labour as a commodity that principle of selling in the dearest market, and giving as little as possible for the price, which was formerly applied only to land, capital, and merchandise. Its method is that of a civil war between labour and capital in which the decisive battles are lock-outs and strikes, with intervals of minor adjustment by industrial diplomacy. Trade Unionism now maintains a Labour party in the British Parliament. The most popular members and leaders are Socialists in theory; so that there is always a paper programme of nationalization of industries and of banking, taxation of unearned incomes to extinction, and other incidentals of a transition to Socialism; but the trade union driving force aims at nothing more than Capitalism with labour taking the lion's share, and energetically repudiates compulsory national service, which would deprive it of its power to strike. In this it is heartily seconded by the proprietary parties, which, though willing enough to make strikes illegal and proletarian labour compulsory, will not pay the price of surrendering its own power to idle. Compulsory national service is essential in Socialism, which is thus deadlocked equally by organised labour and by Capitalism.

It is a historic fact, recurrent enough to be called an economic law, that Capitalism, which builds up great civilizations, also wrecks them if persisted in beyond a certain point. It is easy to demonstrate on paper that civilization can be saved and immensely developed by, at the right moment, discarding Capitalism and changing the private property profiteering state into the common property distributive state. But though the moment for the change has come again and again it has never been effected, because Capitalism has never produced the necessary enlightenment among the masses nor admitted to a controlling share in public affairs the order of intellect and character outside which Socialism, or indeed politics, as distinguished from mere party electioneering, is incomprehensible. Not until the two main tenets of Socialism—abolition of private property (which must not be confused with personal property), and equality of income—have taken hold of the people as religious dogmas, as to which no controversy is regarded as sane, will a stable Socialist state be possible. It should be observed, however, that of the two tenets, the need for equality of income is not the more difficult to demonstrate, because no other method of distribution is or ever has been possible. Omitting the few conspicuous instances in which actual earners of money make extraordinary fortunes by exceptional personal gifts or strokes of luck, the existing differences of income among workers are not individual but corporate differences. Within the corporation no discrimination between individuals is possible: all common labourers, like all upper division civil servants, are equally paid. The argument for equalizing the class incomes is that unequal distribution of purchasing power upsets the proper order of economic production, causing luxuries to be produced on an extravagant scale whilst the primitive vital needs of the people are left unsatisfied; that its effect on marriage, by limiting and corrupting sexual selection, is highly dysgenic; that it reduces religion, legislation, education, and the administration of justice to absurdity as between rich and poor; and that it creates an idolatry of riches and idleness which inverts all sane social morality.

Unfortunately, these are essentially public considerations. The private individual, with the odds overwhelmingly against him as a social climber, dreams even in the deepest poverty of some bequest or freak of fortune by which he may become a capitalist, and dreads that the little he has may be snatched from him by that terrible and unintelligible thing, State policy. Thus the private person's vote is the vote of Ananias and Sapphira; and democracy becomes a more effective bar to Socialism than the pliant and bewildered conservatism of the plutocracy. Under such conditions the future is unpredictable. Empires end in ruins: commonwealths have hitherto been beyond the civic capacity of mankind. But there is always the possibility that mankind will this time weather the cape on which all the old civilizations have been wrecked. It is this possibility that gives intense interest to the present historic moment and keeps the Socialist movement alive and militant. (G. B. S.)

SOCIAL PHILOSOPHY. Social philosophy may be divided into two main parts, critical or epistemological and constructive or synoptic. The object of the first is to disentangle the fundamental

categories and principles employed by the special social sciences and to test their validity. On its more constructive or synthetic side its business is to correct the onesidedness of the specialized social studies and to endeavour to see social life as a whole. In this respect it is greatly helped by the growing science of sociology (the study of human interactions, their conditions and consequences), but it differs from the latter chiefly in its attitude to the problem of value. While sociology cannot exclude from its field of study the psychology and history of ideals in so far as they act as agents influencing human behaviour, it is not as such concerned with the validity of these ideals. Social philosophy on the other hand deals with the validity of the application of ethical categories to the phenomena of social life and development which it studies from the point of view of their contribution to ends or purposes to which we can ascribe intrinsic value.

I. AN EXAMINATION OF SOME OF THE CATEGORIES USED IN THE STUDY OF SOCIETY

It is clearly impossible to attempt here even in outline a discussion of the logical and epistemological aspects of all the social sciences. Attention will be confined to a consideration of the validity of some of the categories that have been applied to the phenomena of social life by those who have approached the subject from the point of view of biology. (*See* SOCIAL PSYCHOLOGY.)

The Theory of a Social Organism.—Societies are frequently said to form organic wholes, and it is implied that there are fundamental laws of development common to organisms and societies (*cf.* especially Dr. Rivers, *Psychology and Politics*, p. 62). There are certainly many respects in which organic wholes and societies do resemble one another in a striking manner. Both may be said to constitute wholes consisting of parts standing to one another in relation of mutual causal dependence of such a nature that the character of the parts depends upon their relation each to the remainder. Both are systems which maintain themselves as wholes by a correlation of functions. Both exhibit a certain adaptability and plasticity of adjustment to a varying environment. Societies like organisms, moreover, vary greatly among themselves, in complexity, differentiation of function, degree of central control and of inner unity or harmony. Accordingly a classification of forms of unity among organisms may prove suggestive in dealing with types of societies. Nevertheless the analogy breaks down in important points. This may be seen best by a comparison between the "higher" organisms and the "higher" societies. In the first place, the latter are much more plastic than the former. In the higher organisms the parts tend to lose their independence, they have no "freedom" in relation to the whole. The more developed a society is, on the other hand, the greater the mobility and freedom and independence of its constituent parts. In the second place, the relations of the parts to the minor or secondary systems within the greater whole differ profoundly in the two cases. The parts of an organism cannot move from one system to another nor interchange functions so readily as can the constituent parts of the higher societies. In short, the individuality of the parts in societies is such that the wholes formed out of their interrelation may well be of a different order than the wholes formed out of the union of cells in the living organism, and the laws of development applying to the former species of wholes may differ radically from the laws applying to the latter.

Biological Change and Social Change.—A study of social change confirms this conclusion. Social change appears to be in the main independent of alteration in racial or inborn characters and proceeds rather by modification of tradition having but little relation to change in biological types. In support of this view several considerations may be offered. To begin with it is generally accepted that in historical times, at any rate, no changes of importance have occurred in either the physical or mental innate equipment of man. Accordingly the vast historical changes that have taken place cannot be attributed to variations in germinal structure. More specifically there is no evidence that any of the striking advances made at various critical periods in human history were due to or accompanied by change in the inherited constitution of man (*cf.* Galton, *Inquiry into Human Faculty*, p. 129). The causes leading to sudden eras of progress are to be found rather in a new orientation given to human faculty, furthered, it would seem usually, by contact with new or strange cultures. Culture contact is more important in this respect than race contact or fusion. Finally forms of culture do not appear to be definitely correlated with forms of race grouping. In other words biological groups do not correspond to culture groups and so far no success has met the efforts made by anthropologists to link up species of civilization with the genetic qualities of race-types (*cf.* T. H. Morgan, *Evolution and Genetics*, 1925, pp. 206–207).

The chief defect of most biological interpretations of society lies in their failure to realize the extreme subtlety and complexity of the relations between human character and the environment. Man's inherited propensities are mere potentialities, part conditions of development whose concrete filling is supplied by the social environment and the individual's own experience. Through this interplay changes in the social environment can bring about changes in human behaviour in a manner independent of alteration in race qualities, and through the agency of forces differing radically from those which are operative in the field of biology.

Thus (1) to the biologist the inheritance of "acquired characters" and its rôle in the evolution of species is a matter of great doubt. In social evolution it is clearly of the greatest importance. What is acquired by one generation is transmitted to the next, either as a totality or, at any rate, as facilitating reacquisition. This makes possible cumulative change inexplicable in biology. (2) In the biological field, the formation of new types by the accumulation of small individual differences is improbable. In social matters vast changes are clearly brought about by the accumulation of small differences. (3) There is no evidence that the occurrence of one mutation in itself favours the occurrence of others in a similar direction. One of the outstanding difficulties of natural selection is to account for the appearance of correlated structural changes. In the human sphere, on the other hand, a new idea is an excellent stimulus to further new ideas. (4) Inventions are far more common than mutations. This obvious fact has important bearings upon the problem of the relation between racial qualities and social change. Enormously significant changes can be brought about in a society without involving any changes in the inherited structure of the race. (5) Social changes, unlike mutations, can often be explained as the result of co-operation, as is best illustrated from the history of science and invention. (6) Whether the chances of the occurrence of mutations increase with changes in the environment is a matter of doubt. In the case of social mutations or inventions, it can be shown that great changes and upheavals act as stimulants, and that social or cultural advance is favoured by variability in the environmental conditions and the clash of ideas resulting from contact with new cultural elements. (7) The problem of orthogenesis or evolution in what appears as a directed line which has so far remained a mystery to the biologist is more readily explained in social evolution. The effects of changes in the environment are here cumulative and each new generation can start on the basis of what has been acquired by past generations, since the method of transmission does not depend on the mechanism of physical heredity. (8) Finally the source of variation in social affairs is not nearly so mysterious as is the cause of mutation in biology. For in human life teleological factors are plainly operative. Changes are brought about by a process of trial and error and by deliberate effort directed to ends more or less clearly apprehended. Whatever be our view of the rôle of mind in organic evolution, there can be no doubt of its importance in social evolution.

At this point the biologist might retort that conation and purpose are activities centred in some mind and mind itself grows up under the conditions determined by survival value, so that in the end we are driven back to biological agencies summed up in the term natural selection. This argument, however, is based upon what appears to be an erroneous view of the rôle of selection. Selection is not an originative agent and mind cannot be said to be its product. Nothing is known of the ultimate source of variations and this applies to forms of mind as to other things.

The mind once arisen is, indeed, limited by biological conditions but it gradually comes to control them by a purposeful handling of the environment and in so doing modifies the conditions of its own survival. Natural selection should accordingly not be spoken of as producing improvements or as the cause of progress. It produces nothing, but at most only acts upon existing variations so as to secure a certain definiteness of type. In social evolution the mind operates by adapting the environment to itself rather than by adapting itself to the environment. Changes are not brought about by waiting for the appearance in the course of hundreds of generations of survivors adapted to the new situation. The efforts of the mind are directed at securing adaptation by an increase in plasticity, more and more independent of changes in specific race qualities.

II. THE ETHICAL BASIS OF SOCIAL RELATIONS

The central problem of social philosophy on its ethical side is the nature of political obligation and authority. In this, two essentially different questions are involved which it is important to distinguish. We have first of all to account for the concentration of coercive power in some determinate person or persons and for the growth of habits of obedience to those persons on the part of the other members of society. We have, secondly, to inquire into the ethical justification of social obedience or, looking at it from the point of view of the persons exercising political power, into the moral basis of their authority. Though the two problems have points of contact they are at bottom quite different in nature, the one being a matter for history and psychology, the other for ethics and political philosophy. Into the historical conditions which have led to the emergence of different forms of political organization, we need not here enquire. It is sufficient to point out that although brute force and military conquest have played an important rôle in their determination, yet, in the long run, political power and habits of obedience and social co-operation rest upon a recognition, however vague or dim on the part of the members of society, that the public authority maintains and furthers common interests and common goods. The psychological factors involved, however, are extremely inchoate and obscure. They cannot be described accurately in terms of a common or corporate will. They constitute rather "an impalpable congeries of hopes and fears" resting upon feelings of discomfort and maladjustment experienced when an accepted rule is broken or a common requirement not fulfilled, a dim recognition, perhaps, that somehow order must be maintained and that somebody must be entrusted with the duty of maintaining the social peace. Consent for the majority of the people hardly rises above passive acquiescence, and in complex societies has not the character of voluntary decision. Power rests upon the will of the people in the sense that if stretched beyond a certain point, their acquiescence will not be secured, and social apathy and even disruption may result. Thus the degree of power exercised by a public authority depends ultimately on the amount of obedience it can command, and therefore varies greatly in duration, scope and intensity. If by the term sovereignty is meant supreme or unlimited coercive power vested in determinate persons, then clearly the notion is no more than a convenient fiction of jurisprudence, since no determinate person ever had such power. The attempt to place sovereignty in the general will in the sense of the congeries of vague psychological elements underlying common or joint action must fail, since in this sense the general will is indeterminate and cannot therefore be vested in a person or persons.

The General Will.—In the discussion of the second problem psychology and history have been confused with ethics. It is true that psychologically obedience on the part of an individual may be influenced by his recognition that the law which he accepts is in the common interest, but this recognition by him does not give the law its authority and it is arguable that the law might still be right even if a given individual did not recognize its rightness. The problem here involved has given rise to the theory of a general will. It was thought that a moral imperative must be self-imposed and that obligation consists in this adoption by the self of its own law. Accordingly the problem of political obligation comes to be put as the question how self-government is possible, and the answer is found in the light of a distinction between our momentary or actual explicit consciousness at its ordinary level and our "real being" in which "we will our own nature as a rational being." This real being, it is then argued, is universal, is expressed in the State, and in obeying its injunctions the individual obeys his own real will and is therefore "self-governed." (*See* Bosanquet, *The Philosophical Theory of the State.*)

Now it must be granted that to have true moral value obedience on the part of an individual must be self-imposed, but the ground of the obligation itself is not found in the acceptance or will of the individual, but in the constraint due to the worth or value of the end or ends to which the act in question is directed, and this value is not dependent upon its recognition or appreciation by a given subject or individual. The problem of obligation is not to be solved by an analysis of volition, but rather of the ends or objects which have value, by an analysis not of willing but of what is willed. But, it will be said, society is a condition of there being any ends or objects of will at all, or perhaps more precisely that just those ends which are of the greatest significance for the growth of individuality are those which society (or man's social nature) lays on him. (Hetherington, *Aristot. Proc.* 1917–18, p. 304.) It would follow that the constraint, control and stability which an individual owes to the ends in which he is interested are socially conditioned, and this, it may be said, is what is meant by the operation of the general will on the individual.

Here again it must be urged in reply that though psychologically the individual would not come to form ends apart from society, and though some ends are as such social in nature in the sense that they relate to other persons or depend upon co-operation for their realization, it is not their social nature that makes them morally binding, but rather their intrinsic value or worth. Common ends may have greater value as being more inclusive but the value itself may consist in something other than being included in a whole (though wholeness or completeness may be *a* value).

We must therefore abandon the attempt to find a repository for obligation in the real will. Nothing is gained by the argument that what *ought* to be willed *really* is willed by some one (God, our best self, etc.). It remains true, however, that as a matter of psychological fact institutions may be said to embody the efforts of social individuals towards mutual adjustment and the attainment of common ends. But this is a mere generality which throws no light upon the nature and value of any particular institution or association, or of the relations between them. The weakest side of the theory of the general will, since its formulation by Rousseau, has always been that it has tended to waver between two different conceptions which it does not succeed in bringing into an intelligible relation to one another. On the one hand the general will is identified with an ideal good, that in which all human purposes would be unified and harmonized. In this sense the general will is not a "*de facto* tendency," but something "essentially logical," that is to say, something logically implied in human endeavour as that which, if fulfilled, would make it complete and systematic. On the other hand, the general will is conceived as something determinate and capable of expression, "a community of view as to the good of social and individual life" (Hetherington, *Arist. Proc.* 1917–18, p. 307), "an effective community of will." If now we follow the first interpretation, it is clear that our ultimate obligation is to the final good which is only inadequately interpreted by any actual institution. If we are told that the State is the "operative criticism of institutions" and our loyalty is to it, it remains to explain the nature of the principles upon which such criticism is based. Moreover, as a matter of fact, effective moral criticism is often rendered by individuals or associations within the State which reach an ethical level higher than that reached by the organized machinery of the State. Again, the principles employed by such criticism are of universal applicability and may go beyond the limits of the State. It is worthy of note in this connection that according to the theory of the real will there is no general will of humanity. If the "real" will is the ideal will can there *really* be no will of humanity? If we elect to

stress the second interpretation of the general will as a determinate community of will, we must challenge its upholders to produce psychological evidence of such a unitary corporate will in the large States of the western world. The relation between "determinate levels" of the real will and the general will remains as obscure as the relation between finite individuals and the absolute spirit in idealist metaphysics.

The Attack on the State.—The issues involved in the above arguments have not been clearly brought out in recent controversy relating to the notion of the sovereign State. Instead of questioning the validity of the theories which seek to find a basis for obligation in will, political theorists have merely sought to replace the unitary will of the State by a plurality of separate wills (Guild Socialism, and kindred movements), amongst which that of the State was *prima inter pares*. Insoluble problems of functional demarcation were thus created and the need of a co-ordinating body had to be admitted, which dangerously resembled the unitary State which these theorists had set out to attack. It has proved difficult to work out the respective spheres of authority of the separate functional wills, and it has had to be admitted that in some sense the State does penetrate into all associations. It is now coming to be recognized that the failure of these efforts was due to the fact that the problem to which they sought to supply an answer was badly formulated. The question is not whether there is one will or many, but whether political obligation is not essentially secondary in character, deriving its authority not from the fiat of any personal will but rather from the moral law, which is above all human organizations whatever. It is true that the moral law has to be interpreted by organs set up by society, but social institutions have authority only to the extent to which they in fact promote the social good, and they must be judged by what they do. It is idle to maintain that the State *qua* State is always good and that the general will cannot err. The content of such will must be scrutinized and evaluated in the course of its actual expression. It follows that ultimately the individual conscience is the final arbiter. The problem before the individual is not, however, that of reconciling clashing wills or of putting his "own good" against that of others. No really satisfactory theory of obligation can be built on the basis that in serving others I am *really* serving my own interest. Such a notion of the common good assumes a harmony between competing interests which in a complex world is not warranted by facts, and cannot in any event account for genuine self-sacrifice. The ultimate principle seems to be that the good is binding and should be promoted wherever and by whomsoever it may be achieved, and that in this respect the individual agent counts for no more and no less than any other similar agent similarly situated. For the ambiguous category of the common good it is better to substitute the notion of just distribution of goods, and the problem is in every case to determine the conditions which would secure the justest distribution of goods among all those affected, or more generally to formulate a system of rights and obligations based upon principles of justice.

Such principles must be based upon the idea of equality. By this is not meant the view, often ascribed to egalitarians by their opponents, that all men either are equal in capacity or endowment, or that all should be treated alike, but rather that all persons have similar claims in so far as they are similar, and that only such differences should be taken into account as are relevant to the values or goods involved. Equality, in short, is a principle of proportion, as Aristotle long ago pointed out. It is not based upon a denial of differences but upon an evaluation of the relevance of such differences as do exist to the system of rights and duties.

We are confronted here with the difficulty that our notion of the good life is still very indeterminate. In mitigation it must, however, be remembered, that social philosophy is concerned not with the detail of the good life but only with those general conditions of such a life as can be promoted by organized society. Rights are claims to such conditions for the realization of the good as can be secured by social organization. The delicacy and subtlety of organized effort varies from association to association and, in the case of the State, it is clear that its action is relatively mechanical and confined to measures which can be carried out in a relatively uniform manner. This limitation, arising from the character of the means or mechanisms at the disposal of the State, and the further difficulty due to the absence of agreed scales of values, rather than any *a priori* theorizing as to the scope of the State, determines the limits of its intervention and control. For practical purposes these considerations lead us to the conception of a minimum. The organized efforts of society should be directed at securing the minimum conditions requisite for the realization of the good. The duty of the social authority is accordingly:

(*a*) To utilize the collective resources for the promotion of the good of the associated members in the sense of securing to each individual the minimum facilities for the fulfilment of his capacities for good.

(*b*) To control such differences in power and possessions as arise in a society with the object of preventing those who have acquired excess of power from abusing it and forcing others into conditions incompatible with the requirements of the good life.

The principle of equality is clearly in harmony with the conception of a minimum here outlined, but may also sanction differential claims above the minimum should their satisfaction be shown to be necessary for the realization of the good on a maximum scale. The free working out of the implications of this principle would require, among other things, a knowledge of the extent to which individuals differ among themselves in respect of capacity for the attainment of objects having intrinsic value.

The State and Other Associations.—It is clear that with regard to objects of the greatest value in life (such as appreciation of beauty, truth, personal affection) large scale organization, and especially the State as an organ of compulsion and coercion, can do very little. When we are told that the State exists for the sake of the good life, it should be pointed out that it can only be effective if it confines itself to laying down general conditions to which individuals and associations of individuals under a common rule must conform if the good is to be realized. It can operate only with general rules and is utterly incompetent to enter into the finer questions that come from the need of balancing or grading values against one another. In a sense the sphere of the State is wider than that of other associations within it, since it must lay down certain general conditions to which they must conform, and has further the duty of adjustment and co-ordination. In this sense the State is an organ for the maintenance of justice or the rule of equality. But the complexities of human life and the nature of the ends to which we ascribe value make it practically impossible for the State to intervene effectively except to secure the barest and crudest conditions of general welfare. To maintain that the State alone "reaches like wisdom from end to end" (J. H. Muirhead, *Mind*, 33, p. 364) is not very convincing. The purposes of the State are more embracive than those of other institutions, but the embrace is not tender nor very moving and may evoke but a half-hearted response. It touches all things it is true, but only superficially. The deeper purposes of life are utterly beyond its grasp and its power of arbitrament and adjustment in matters of external action, though necessary, afford no solution of the deeper conflicts of the mind in its struggles towards comprehensive values. There are also many purposes and interests, religious, artistic and intellectual, which cut across State boundaries and either have, or ought to have, organs of expression, just as entitled to our allegiance and loyalty as political organizations. When it is said that the State is the whole complex or system of institutions it should be remembered that some institutions transcend political boundaries and it is questionable whether the State has, or ought to have, "the last word" in cases of conflict or divergence among themselves, or between them and the State. This applies even with greater force to disputes between States. They cannot *each* have supreme authority. That can only lie in a world organization. In dealing with the problems of conflicting allegiance and loyalties that thus arise the individual must be guided by a devotion to the best, and in this arduous task of interpretation and evaluation he may find that "Sittlichkeit," like patriotism, is not enough.

The State and the Problem of Responsibility.—Within its

own territory the duty of the State is, then, to maintain a system of rights and to use the collective resources of the community for the promotion of the good life of its members in accordance with the principles of justice or the rule of equality. But this rule is of universal applicability, and justice enjoins the promotion of the good wherever possible. In so far as the State is concerned, however, it is seen that it is limited by the nature of the means at its disposal and, obviously, by the amount of obedience and willing support it can get from its members. It is clear that its first duty is to promote the good of its own members, not because no one else has a claim, or that the good of others is less important, but because of the greater probability of its being able to secure the conditions required for this realization of the good of its own members than that of others of whose requirements it can have no intimate knowledge, and over whose resources it has no effective control. ("Egoism is undoubtedly superior to Altruism as a doctrine of means: in the immense majority of cases the best thing we can do is to aim at securing some good in which we are concerned, since for that very reason we are far more likely to secure it." [Moore, *"Principia Ethica,"* p. 167].) One may go further and say that, in general, it is dangerous for States to seek to promote the good of others, though it has not been uncommon for civilized States to justify their claims to govern the "uncivilized," on the ground that their suzerainty is for the good of the latter. It is odd that those who have maintained that "there is no recognized moral order," to guide States in their relations with one another, have not felt the difficulty of the appeal to moral considerations so often made by white peoples in their dealings with other races. If each State is the guardian of a moral world but not a factor within an organized world there could never be any justification for any attempt to impose the criteria of one "moral world" on any other "moral world." In opposition to such views it must be urged with the utmost emphasis that moral principles are universal, though their application to the problem of international regulation may present greater difficulties than that with which an individual is confronted in cases of perplexities of conscience. The greater relative difficulty, however, arises not from the absence of principles but from the complexity and intricacy of the problems to which they have to be applied. The principles themselves, though they may not as yet be recognized by the whole of mankind, are binding in the sense that they ought to guide States in their mutual relations. Much has been made in this connection of the difficulty of deciding where responsibility lies. But this again raises no real problem of principles. Men acting in concert do not *on that account* lose their responsibility, though the precise incidence of responsibility in group action may vary according to the nature of the group, the genuineness of the control shared by its members, the degree to which the authority of the leaders and agents is based upon active consultation with the rest of the members, and so forth. In practice we certainly recognize differences in degree of responsibility among the members of a group. The responsibility of an ordinary citizen who refrains from protesting against, or merely acquiesces in, an unjust war, is real, but not so great as that of those who actively participate in it or of the statesmen directly concerned in bringing it about. The tradition of the English law of corporations has, it seems, always been to endeavour to fix responsibility upon some person who can be held accountable, and through whom the activities of the group can be controlled. Ethically the individual is not absolved from responsibility merely because he is acting on behalf of a group, even though that group be the State. The actions of States in turn must be judged by the same principles as those which bind individuals or groups of individuals. The most urgent task of the social philosopher is to apply the universal principles of ethics to the problem of international morality and law.

SOCIAL PSYCHOLOGY: *see* PSYCHOLOGY, HISTORY OF.

SOCIAL SERVICE. The term social service has a somewhat different meaning in Great Britain and America.

GREAT BRITAIN

The term social service is a comparatively new one in Great Britain. If it had been used previous to the 20th century it would have meant philanthropy and charity in the ordinary sense. Now it includes not only personal social service but all the principal public social services, especially the voluntary work attached to these. It is distinguished from the older philanthropy by its scientific and systematic character, by its insistence on seeking out the causes of social evils and by its broad study and action.

Personal Social Service.—This need not be charitable. There is much personal service in relation with Boy Scouts and Girl Guides. In the former case Sir Robert Baden-Powell rightly understood juvenile psychology, and the movement has grown with amazing rapidity. The Girl Guides have employed hundreds of well-educated young women who have rendered good service to the community by the training and discipline they impart. The older movements of Boys' and Girls' Brigades do excellent work.

The physical well-being of the young is dependent upon places in which to play, and the National Playing Fields Association, which began in 1925, is trying to open up the country for their recreation. The movement is rapidly spreading. Much time is given also to guilds of play and folk dancing and both men and women who have leisure can serve the rising generation by giving their time to these movements. Another important development is the growth of camps for boys and girls in connection with innumerable clubs and societies. Here the senior boys and girls from public schools have rendered great assistance. For those who are older the Co-operative Holiday Association and the Holiday Fellowship reach a class already interested in open air life. A great deal of personal service is given by such institutions as the Y.M.C.A. and Y.W.C.A. The men's clubs and institutes are well known, but women's institutes are becoming an important feature in British national life not only in the towns, but also in the country. Boys' and girls' clubs with their national organizations and "Toc H" give opportunity for social service. There is a definite tendency to co-ordinate all this recreative work and even the local education authorities are assisting in this, through the juvenile organisations committees set up in 1920. The rural community councils, established in about a dozen counties, represent an important development. They are aided by the Carnegie United Kingdom trust and organized through the National Council of Social Service.

Although established under the aegis of local education authorities, Care Committees are essentially personal. They seek to make friendly contacts within the homes of the people and to link the official with the parents and the children. Voluntary effort has here been most successful, and there are over 1,000 care committees in London. Medical and dental inspection in the schools has enlarged the scope of the care committees and also the choice of employment.

The Charity Organisation Society is the principal society that investigates the condition of the needy and the unfortunate. The committees are composed of voluntary workers although the secretaries are whole time expert agents. In many towns guilds of help and councils of social service embrace the Charity Organisation Society branches and provide opportunities for service.

Settlement and similar institutions have enabled many like Charles Booth, B. S. Rowntree or Prof. Bowley to carry out investigations into poverty and have marked a new stage in social inquiry. There are now comparative studies of a great many places such as Oxford, Cambridge, Ipswich, Hornsey and West Ham. Such social surveys are required for every large town or

city. Personal services rendered by public schools, colleges and other institutions have opened up a large field of social work in the shape of public school and college missions and settlements. The Cavendish club of London is an outcome of this movement.

One form of personal social service inaugurated by the Mansfield House Settlement in Canning Town was the "poor man's lawyer," the idea being to give free legal advice to the very poor. This effort has been widely extended and has now been regularized by the law societies.

Public Social Service.—In the sphere of public health (*q.v.*), voluntary agencies are doing much to assist the local authorities and the Government.

Although most British hospitals are voluntary efforts and utilize the service of unpaid workers, they are gradually taking on the character of public service. Indeed the poor law authorities are responsible for large numbers of hospitals and infirmaries. There is a National League for Health, Maternity and Child Welfare which has done much to create a sound public opinion. These are now supported by local grants and government aid. There are ante-natal clinics, baby and child welfare clinics, clinics for children up to the age of 5, followed by medical inspection and treatment of children in the public schools. In all these cases there is much voluntary assistance and it is a form of social service which will shape the whole future of the country.

Compulsory education has narrowed the field of social service, so far as children are concerned, to the work of management and the after-care committees, although a development of interest on the part of parents in the work of the school is being encouraged and spreading with great rapidity.

Adult education (*q.v.*) offers great opportunities for voluntary effort.

Whatever may be the future of the boards of guardians, the sense of obligation to the poor which was formerly expressed through the monasteries or the overseers of the parish is bound to continue. Harshness of administration has gradually been ameliorated owing to a more humane public opinion. The services both of men and women on boards of guardians are often rendered purely as giving an opportunity for social work. The Brabazon Society in giving concerts and entertainments in workhouses and infirmaries has created an atmosphere of friendliness and especially in relation to the children has opened up a sphere of helpfulness. Many guardians take a special interest in emigration, which though it is not a final solution of economic problems does in many cases offer a way out and a prospect of future usefulness.

There are many men and women to-day who accept the position of magistrate because they feel they can thus serve society most effectively, and by exercising wisdom and patient consideration enable those who have transgressed the law to recover good citizenship. In connection with the criminal system a good deal of social work is carried on in connection with the Borstal institutions, remand homes and prisons, while the work of probation officers, whether paid or voluntary, in connection with children's courts has wrought a veritable revolution in the treatment of young offenders. (P. A.)

THE UNITED STATES

Social service or social work, as understood in the United States, is that form of persistent and deliberate effort that helps the individual (or family group) to make a satisfactory adjustment to his environment. In another aspect it attempts to provide those aids to living which make for a richer and more wholesome existence. In still another aspect social work, through scientific research, is searching out the causes for human distress, measuring the incidence of poverty, ill health and delinquency, etc., or seeking an evaluation of the methods of treating these ills and the character of the results achieved. Finally, social work is engaged in reform. Through legislation, improved administrative procedures and public education, the struggle to improve living conditions and promote social justice is carried on. As the social worker in his daily practice and through research becomes conscious of wrongs and inequalities, he seeks a remedy and becomes an active protagonist of the changes needed to achieve that end.

Groups of Workers.—Social work is carried on by three groups of workers, *i.e.*, the practitioners who serve dependent families, run settlements, playgrounds, boys' and girls' clubs or serve as probation officers in courts, etc.; the research specialists who are technically trained to do the scientific work which must underlie and guide the progress of the practitioner and who point the way toward social reform; the propagandists and reformers who through writing, speaking, public education and varied forms of agitation help to bring about that better day which men are forever seeking and never fully attaining.

For such tasks as these there are needed education and training of a professional character. Whereas, in an earlier day, any person of "good intentions" and with a desire "to do good" was regarded as qualified to engage in philanthropy, it is now generally recognized that special disciplines attained through colleges, universities and schools of social work are essential. There now exists (1929) a professional organization with nearly 5,000 members, known as the American Association of Social Workers, membership of which is based upon a high professional standard.

Classification of Activities.—The breadth and variety of the activities known as social work may be best indicated by reference to a classification adopted by the Welfare Council of New York city—a clearing house and co-ordinating centre for its 1,200 welfare and health organizations.

Family Welfare.—Under this division are found the following groupings: *Family Service,* charity organization societies that serve dependent families; *Relief Societies,* which provide material assistance but do not engage in "social case work"; *Legal Aid,* societies providing legal service for those unable to pay for it; *Immigrants, Foreign-Born and Travellers,* organizations that assist the immigrant in making his adjustment to the new country; *Homeless,* a group that provides care for those adrift from family, relatives and home; *Seamen,* special services for seamen in American ports; *Care of the Aged,* institutions and homes for aged persons and organizations giving help outside the institutions; *Housing,* societies concerned with improved housing conditions and legislation to attain that end; *Protective and Correctional Agencies,* institutions for delinquents and criminals, prisoners' aid societies, probation and parole, etc.

Child Welfare.—Under this division are: *Dependent Children,* institutions and agencies giving care to children without adequate parental and home supervision; *Day Nurseries and Nursery Schools,* where children are cared for while the parents are away from home in employment; *Auxiliary School Services,* which provide clothing, lunches and special types of aid to children in the public schools; *Summer Camps and Vacation Houses,* which are concerned with providing outings and vacations for children during the summer.

Public Health.—This division includes organizations interested in the promotion of public health through proper *Health Administration and Health Education; Public Health Nursing* organizations, which provide nursing service to those unable to supply it for themselves; *Hospitals,* administered under both public and private auspices; *Clinics; Medical Social Service,* the departments of hospitals that provide special help and service to patients in need; *Convalescent Care,* agencies and institutions serving the patient in convalescence; *Mental Hygiene,* clinics, bureaus of child guidance and other organizations dealing with the problem of mental hygiene.

Neighbourhood Work.—Includes organizations grouped under these headings: *Recreation; Neighbourhood Houses and Settlements; Neighbourhood Associations; Boys' Work; Girls' Work; Education of the Foreign Born; Technical and Professional Education; Employment and Vocational Guidance; Education of the Handicapped.* In addition to the foregoing should be mentioned community organizations whose task is not to serve individuals in need but rather to serve as a co-ordinating centre and clearing house for the various service agencies that exist in the community. These are known as "councils of social agencies," and in many cities are found "community chests" which raise money for philanthropic purposes through a central organization.

Administration.—Social work began very largely as an ac-

tivity of the church; it is now carried on under the auspices of many different organizations. Public departments, Federal, State, county and municipal, are engaged in welfare work of varied sorts. Public hospitals, institutions for the insane and feeble-minded, almshouses, orphanages, homes for the aged, etc., are maintained everywhere by local governments. Other relief administered usually by city and county authorities is now supplemented in most States of the Union by so-called mothers' pensions, *i.e.*, subsidies to enable mothers to keep their dependent children with them in their own homes. State and local public welfare departments are charged with the administration and enforcement of welfare laws designed to protect children and others who are underprivileged or maladjusted. Most large communities now have highly socialized courts such as juvenile courts, dealing with neglected dependent and delinquent children, and family courts which have jurisdiction over such matters as divorce, the enforcement of orders for support, abandonment and desertion, etc.

Voluntary Organizations.—In the field of social service carried on by voluntary organizations supported by the contributions of citizens rather than through taxation, there are various types of societies maintained by churches, nationality groups, fraternal organizations, etc. By far the largest amount of work done in the field is carried on under the auspices of these voluntary and privately supported societies. Some of the work done by recreational organizations and settlement houses is paid for in whole or in part by the beneficiaries of these services and a growing portion of the income of many philanthropic organizations is derived from dues paid by members and from payments for service made by the beneficiaries. (W. Ho.)

SOCIAL SETTLEMENTS. In Great Britain this term is applied to settlements of social workers in depressed areas, whose object is the relief of poverty and its consequent effects. After the opening of Toynbee Hall in 1884 a large number of other settlements sprang up in London and the provinces. Some like Oxford house in Bethnal Green and Cambridge house in Camberwell are connected with a particular university; some like Mansfield house in West Ham with a particular college. Some of the settlements are for men and some for women only. Others like the Manchester University Settlement have separate houses for men and for women. Unlike Toynbee Hall, which has always been non-denominational and non-party, certain settlements are connected with a religious body, usually the Church of England, but no settlement imposes any sort of test upon those who desire to benefit by its operations. Generally all settlements share the ideals of Canon Barnett, the founder of the settlement movement thought they may differ from him and from one another as to the emphasis to be placed upon the several aspects of their work. Thus while some of the settlements are intimately connected with the local government of their areas and encourage their residents to serve on the borough council or board of guardians, others through clubs of all kinds and societies and meetings concentrate upon the personal element in the life of the neighbourhood. It may however be said of all the settlements that though, owing mainly to the development of social legislation in Great Britain they are not as much as heretofore absorbed in tasks connected with the poor or destitute in their areas and tend more than in Barnett's day to specialize in some aspect of social work, they are concerned to further social investigation, education for the young and particularly for the adult, the work of such bodies as the care and after care committees and of such representatives of the public as the school attendance officer and the probation officer. Further all the settlements are the centres of voluntary bodies such as the Children's Country Holiday Fund, the Invalid Children's Aid Association and the Skilled Employment Committee and all are actively assisting the work of such agencies as the Boy Scouts and Girl Guides. Most settlements moreover provide a service of "poor men's lawyers" and are generally willing in any sort of emergency to act as poor man's friend.

Since the end of the World War, the settlements in Great Britain have been drawn together by the Federation of Residential Settlements through which the individual settlements exchange ideas and afford one another various kinds of assistance. The Federation is concerned to promote settlements in areas which seem specially to need them. It has recently established a settlement in one of the villages in the new Kent coalfield and other settlements in socially backward areas are in contemplation. About 50 settlements are affiliated to the Federation of Residential Settlements. Educational as distinct from residential settlements are a development of recent years. Such settlements do not depend upon helpers from the universities and under the direction of a Warden seek to organize higher education in the locality and generally to promote its cultural life. This type of settlement because of the relatively small expenditure which it involves and its singleness of object is particularly suitable to areas inhabited by artisans who desire facilities for education and discussion.

There are settlements in several European countries and in Japan and China but these settlements are not numerous and they tend in important respects to differ from the British type of settlement. The widespread character of the settlement movement is to be judged by the fact that at the first international conference of settlements held at Toynbee Hall in 1922, 21 countries were represented by nearly 300 delegates. At this conference a committee was appointed to keep the settlements in the affiliated countries in touch with one another and to arrange from time to time for the holding of other conferences. A second conference was held in Paris in 1926. (J. J. M.)

The United States.—The founders of the first settlements in the United States lived at Toynbee Hall or talked with Samuel A. Barnett. Neighborhood Guild (University Settlement), the first American settlement, was established August 1886 on the lower East Side of New York by Stanton Coit; Hull House, Chicago, and College Settlement, New York, June 1891; Northwestern University Settlement, Chicago, and South End House, Boston, December 1891. The number reached 103 in 1900 and 413 in 1911. The World War halted the establishment of new houses. In 1928 there were between 600 and 700 houses.

Purpose.—Settlements provide opportunities for working people to meet neighbours and friends and to become acquainted with educated men and women; organize classes in any subject-matter for which there is demand; and obtain for their neighbourhoods better organization of professional service, relief in crises, legal protection against exploitation, improved municipal and governmental public services and public and semi-public recreation. Neighbourliness or friendliness as a means of understanding the problems and point of view of individuals and groups is fundamental. Residence in the area served identifies the settlement staff with the community and its problems. Interpreting the significance of the life of working people to themselves and to the community at large is continuous. Jane Addams (Hull House) has told of the needs and aspirations of individuals and groups with such moving insight and sympathy that all classes have come to think of others with more understanding.

Health.—Lillian D. Wald (Henry Street Settlement) organized the district nursing service for New York city, originated school nursing and helped secure the Federal Children's Bureau. Investigations into midwifery (Union Settlement, New York) and into fly borne typhoid (Dr. Alice Hamilton, Hull House) are typical settlement contributions to public health. Fewer clinics are maintained now than formerly, but more examinations and follow-up in connection with gymnasiums, summer camps, classes in homemaking and women's clubs.

Poverty.—Julia Lathrop (Hull House) brought about improvements in public administration of poor relief in Illinois, and Robert A. Woods (South End House) helped obtain a law which reduced vagrancy in Massachusetts. Settlements in several States assisted in obtaining mothers' pension acts. Most houses cooperate with the family welfare societies in cases of acute need, but do not themselves give relief.

Wage Earning.—Mrs. Florence Kelley (Hull House) and Robert Woods were leaders in the movement to raise the compulsory education age from 14 to 16 years. Graham Taylor (Chicago Commons) has interpreted trade unions and working class life to the Protestant Churches. Mary E. McDowell (University of Chicago Settlement) started forces that led to the

Federal investigation of the conditions of women and child wage-earners in the United States, 1910–1913. John L. Elliott (Hudson Guild) founded a school for printers' apprentices managed jointly by representatives of employers, labour unions and the settlement. The steps which led to the organization of industrial guidance in the public schools were taken at Civic Service House, Boston.

Recreation.—Charles B. Stover (University Settlement, New York) has been a national figure in the playground movement. Public playgrounds, baths, gymnasiums and school centres have been obtained by settlements in many cities. The remarkable public recreation centres in Chicago owe much to Hull House, and in Los Angeles to Bessie D. Stoddard (College Settlement). A great deal of effort continues to be given to promoting public and semi-public recreation.

Clubs and Sociability.—Sociability is an important means through which individuals and groups are trained in ways of living together harmoniously and productively. Settlements were the first to point out the theoretic and practical importance of the "gang" or "natural group" as a useful social instrument. Clubs are usually federated into "councils" which provide training in representative action. There are relatively few men's clubs. The settlement women's clubs have brought the tenement wife and mother into the great woman movement. Classes in physical culture, in home-making and in dancing are an important interest with girls, and athletics and wood work with boys. Summer camps have developed into an educational resource of major importance. The first settlement music school was established by Eleanor Smith (Hull House) in 1892, and there are now (1929) 15 schools with advisory boards of artists, highly trained faculties, and well-rounded curricula; and more than 100 music departments. Drama and the dance have had a similar development. The number of "little theatres" and permanent companies of players grows steadily. Classes in drawing and modelling and pottery are increasing, and needlework departments at a score of houses do work of high practical and educational value. Jane Addams and Mary K. Simkhovitch have made Hull House and Greenwich House (New York) outstanding in range and quality of cultural activities.

Federations of Settlements.—City federations of settlements (1896 ff.) are found in 8 cities. Inter-settlement athletics, art exhibits, dramatics, lectures and gatherings are arranged. Committees on public affairs and legislation are usual. The federated settlements have been influential in child labour and housing legislation, and in control of the liquor trade. A national federation of settlements (1911) included 170 houses of first importance. It holds an annual conference, carries on studies (prohibition, 1927; unemployment, 1928), publishes monographs and a quarterly journal, co-operates with other national agencies and takes occasional part in legislation.

Present Tendencies.—New buildings of exceptional quality are becoming common, *i.e.*, Kingsley House, New Orleans. Endowments are increasing. Programmes are being adjusted to the more comfortable working class income. Housing, irregular employment, adjustment of family relationships, the promotion of understanding across racial, national, religious, economic and social borders engage many leaders. Significant experiments in new forms of co-operative and cultural enterprise, *i.e.*, camps and handwork, are going on. The settlements serve as a bulwark against over-centralization of education and philanthropy. They resist the tendency to stereotype culture, seek for evidence of new life in their communities, and promote adjustment of all kinds in advance of social strain.

SOCIETÀ ANONIMA "ANSALDO," Italian Mechanical and Electrical Engineering Company, Genoa, was founded in 1846, when an Italian engineer, by name G. Ansaldo, set up a small engineering workshop for repairing locomotives and steamers entering the port of Genoa.

The plants which the company owns enable it to undertake any process in mechanical, electrical and naval engineering. It maufactures, not only hulls, boilers, engines, guns, armour-plate and ordnance material generally, but also locomotives (electric and steam), dynamos, transformers, alternators and metallurgical material of every kind.

During the World War the company established new plant and transformed itself into an organization for the production of munitions. At this time, it employed 50,000 people and supplied no fewer than 10,000 guns to the Italian navy and army, in addition to enormous quantities of ammunition and war material of every description. After the World War the company turned to production for peace purposes, developing especially its engineering and electrical works. On the engineering side, special attention has been paid to the construction of steam turbines for marine and land installations, and also to the construction of steam and electric locomotives, and railway carriages and wagons of every type and size.

The present capital of the company is 125,000,000 lire, and its headquarters and main works are situated in the port of Genoa. (E. N.)

SOCIETÀ TRIESTINA DI NAVIGAZIONE COSULICH. Founded in 1903 by the brothers Callisto and Alberto Cosulich, whose activities were for a long time devoted to shipbuilding, the Società Triestina di Navigazione Cosulich rapidly established itself in the maritime world, and in the short period of ten years increased its capital from two to 24 millions of Austrian crowns. In 1913 its fleet consisted of 29 liners, while five more were in course of construction at the naval shipyard at Montefalcone, near Trieste.

The World War checked development, but as soon as business resumed in the port of Trieste, its activities started once more. The capital was increased various times and has reached 500,000,000 lire. A reconstruction of the shipyard at Montefalcone permitted the building of the large motor vessels "Saturnia" and "Vulcania" (24,000 tons each). At present the total tonnage of the fleet is nearly 200,000.

The services performed by the vessels of the Company are:

1) Trieste-Naples-Marseilles-New York Express.
2) Trieste-Buenos Aires Mail Service.
3) Trieste-South America Cargo Line.
4) Trieste-Savannah-Wilmington Cargo Line.
5) Trieste-Mexican Gulf Cargo Line.
6) Trieste-South America Cargo Line.

The Company's association with powerful concerns such as the Steamship Company "Adria" of Fiume, the naval shipyard of Montefalcone, the Società Italiana Servizi Aerei (Italian Air Services) of Portorose, the Hotel Association of Portorose, the Banca Commerciale Triestina, the Cosulich Financial Company, the Insurance Company of Shipowners makes it one of the most conspicuous organizations of Trieste. The Cosulich Line controls the Lloyd Triestino Line and its affiliated companies, *i.e.* the Stabilimento Tecnico Triestino, S. Rocco Shipyard, Officine Navali Triestine, the Marittima Italiana Steamship Company and the Puglia Line of Bari. The principal services from the Adriatic to the Near and the Far East, North Europe and to North and South America are thus under one control, and the Cosulich, with an aggregate tonnage at its disposal of 500,000, is in a position to provide for a perfect organization of all the services. The Banca Commerciale Italiana is associated with this big fusion of interests. (W. STO.)

SOCIÉTÉ INTERNATIONALE D'ÉNERGIE HYDRO-ÉLECTRIQUE (Sidro), a Belgian company, was formed in 1923. Its original capital of 90,000,000 francs was increased, first to 125,000,000 and then to 162,500,000 francs.

Already at the time of its formation, the Sidro had secured large interests in the Barcelona Traction, Light and Power Company and in the Mexico Tramways Company. It was thus able, for instance, to help actively in the financial reorganization of the Barcelona Traction Company, over which it now practically has full control, and it also controls the Mexico Tramways

Company. But it should be observed that the Mexico Tramways and the Sidro together control the Mexican Light and Power Company; the latter also underwent a financial reorganization in 1927.

Finally the Sidro holds an interest in the Société d'Électricité de la Région de Malmédy, which company, amongst other things, has built a hydro-electric station developing the water power of the River Warche (Belgium). (H. Sl.)

SOCIETIES, LEARNED, are societies or institutions whose members are united in some common interest, organized to pursue some definite line of research, and issue periodical publications concerned with the progress of study in such spheres of human knowledge. These societies are so numerous that it would be manifestly impossible to present a complete list of them in any but a publication devoted to that purpose.

It has been found more convenient to group these societies under the headings of the principal subjects of research, and the reader should therefore look up Astronomical Societies, Botanical and Horticultural Societies, Chemical Societies, and so on to Zoological Societies. Kindred subjects are sometimes grouped, as in Literary, Historical and Archaeological Societies. In cases of difficulty, reference to the Index volume will indicate where the desired article is to be found.

SOCIETIES OF ART. According to a pious tradition St. Luke was a painter, and for that reason, one of the earliest art societies, the Guild of St. Luke in Florence, bore his name. Certain it is that, in banding themselves into societies and associations, artists have always been especially remarkable. The fundamental motive of such leaguing together is apparent, for, by the establishment of societies, it becomes possible for the working members of these to hold exhibitions and thereby to obtain some compensation or publicity for their labours.

GREAT BRITAIN

The growth of cults and the specializing of work have given rise to many new associations in Great Britain, besides the Royal Academy. (*See* Academy, Royal.) At the outset, therefore, it will be well to mention the leading art societies. The (now Royal) Society of Painters in Water Colours, founded in 1804, and the (now Royal) Society of British Artists (1823), are typical of those societies which exist merely for purposes of holding exhibitions and conferring diplomas of membership. The British Institution (for the encouragement of British artists) was started in 1806 on a plan formed by Sir Thomas Bernard; and in the gallery pictures were exhibited from time to time till 1867, when the lease of the premises expired. A few years later, scholarships in painting, sculpture, architecture and engraving were instituted, and they are still annually awarded. The Artists' Society was formed in 1830 to enable its members to perfect themselves in their arts. In the furtherance of a cult the Japan Society, devoted to the encouragement of the study of the arts and industries of Japan, is a typical example. Others in this category are the Society for the Promotion of Hellenic Studies, the Society for the Promotion of Roman Studies, the Egypt Exploration Society, the India Society, the Vasari Society, the Walpole Society, the Blake Society and the Wren Society. The Society of Master Glass-Painters, the Church Crafts League, the Society of Parson-Painters, the Society of Wood-Engravers, the Society of Mural Decorators and Painters in Tempera, the Society of Graver-Painters in Colour, the Colour-Woodcut Society, the Senefelder club and the Woodblock Society are representative of bodies formed in the interests of particular groups of workers. One of the remarkable features in the history of art in Great Britain has been the rapid increase of the artistic rank and file. At the end of 1927 it was estimated that there were quite 10,000 practising artists and designers. Portrait painters, pastellists, miniaturists, women artists, etc. have felt the necessity of organization.

Not until 1903, however, did a society exist in England with the determined object to enlist the sympathies and activities of every kind of art lover, either professional or lay, to help the national art institutions to acquire some of the treasures which were rapidly being bought up by millionaire collectors in other countries. This National Art Collections Fund has had some astonishing successes. At the beginning of 1928 the membership of this patriotic association was nearly 7,000. In this connection the Contemporary Art Society, founded in 1910, should also be mentioned. Founded three years earlier, the Scottish Modern Art Association continues to do similar work in Scotland. In 1909 the Imperial Arts League was formed to provide a central organization to which all members can appeal for advice or assistance in matters of professional business.

Another important society, The Faculty of Arts, was founded in 1921 to cover an even wider field, as it embraces the kindred arts of music and the drama. The British Confederation of Arts is the British section of that international *Confédération des Travailleurs Intellectuels* which has its headquarters in Paris, where the fourth international was held in 1927.

Societies created for the specializing of some study or for the display or protection of some particular branch of practice are tinged more with the spirit of the old guilds than with that of modern trade unionism, such as the British Institute of Industrial Art, with which is incorporated the Civic Arts Association, and the Design and Industries Association. The parent body of these is the Arts and Crafts Exhibition Society.

Exhibiting Societies.—(*a*) Old Established.—Those in London are: The Royal Academy, the Royal Water Colour Society, the Royal Institute of Painters in Water Colours, the Royal Institute of Oil Painters and the Royal Society of British Artists. In the provinces, the Birmingham Royal Society of Artists has been in existence since 1825, and has a life academy with professors attached. (*b*) Modern.—In this category are those which reflect the new spirit which came into artistic life in the last quarter of the 19th century. The New English Art Club, founded in 1885 as a protest against academic art, achieves its purpose by exhibition only, yet it is ironical to add that many of its members have been taken into the Royal Academy. The International Society of Painters and Engravers again represents the wider ideas of the 20th century, but, owing to the lack of a fixed home, is compelled to hold its exhibitions infrequently. The Royal Society of Painter-Etchers and Engravers, consisting of fellows and associates, not exceeding 150 in all, conserves the interests of a large body of workers, and, in addition to holding exhibitions, confers diplomas (R.E. and A.R.E.) on the exhibitors of meritorious etchings or engravings. The Society of Women Artists (formerly the Society of Lady Artists) and the Women's International Art club hold annual exhibitions. In 1891 the (now Royal) Society of Portrait Painters was formed to carry out the object conveyed in its title, but this society and the National Portrait Society suffer, similarly to the International Society, from the lack of a gallery. Undeterred by these obstacles the Portrait Society held an inaugural exhibition in 1928. Two associations advance the art of the miniature-painter, and the Pastel Society, formed in 1898, holds displays of members' work at the Royal Institute Galleries. Other London art societies which achieve their purpose by the holding of periodical exhibitions are such as the Society of Graphic Art for the display of every type of monochrome; the New Society of Artists, founded in 1921; the Ridley Art club (1889); the Old Dudley Art Society; the New Forest Group and the London Group of modernist painters. In Scotland there is the Royal Scottish Academy. The Royal Scottish Society of Painters in Water Colours (Glasgow) grants the title R.S.W. to its members, and the Society of Scottish Artists (Edinburgh), founded in 1891, has a membership of nearly 300 young artists; the artist members and lay members of the Paisley Art Institute which has held an annual exhibition since 1876, number 1,000. There is also a flourishing art society in Dundee. Other exhibiting societies which call for mention are: the Society of Yorkshire Artists (Leeds), which consolidates many local societies; the Nottingham Society of Artists, which also encourages drawing from the living model; the Liver Sketching Club, founded in 1872, which holds an annual exhibition; the Oxford Art Society, founded in 1891; the Bath Society of Artists (1904); the Sheffield Society of Artists; the South Wales Art Society at Cardiff and the Royal Institution of South Wales Art Society at Swansea.

The Belfast Art Society has held exhibitions since 1879, and the membership exceeds 300. In the Dominions the Ontario Society of Artists has held displays in Toronto since 1872, and the British Columbia Art League, founded in Vancouver in 1921, is a very enterprising association.

Societies of Instruction and Popular Encouragement.—In this category the most important is the National Art Collections Fund, already mentioned. The Artists' Society, the Art Workers' Guild, and the Junior Art Workers' Guild, provide meetings, from which the public is excluded, where profitable discussions take place on questions of craft and design. The old Langham Sketching Club (1838) and the London Sketch Club may also be cited as furthering an artist's knowledge. The old Society of Arts in the Adelphi, founded in 1754, has in recent years devised a scheme by which travelling scholarships and awards are made to student-workers in industrial art design. The Royal Drawing Society, 1888, has for its object the teaching of drawing as a means of education.

The great wave of enthusiasm aroused by Ruskin's teachings caused Societies of the Rose to be founded in London, Manchester, Sheffield, Birmingham, Aberdeen and Glasgow; but some of these eventually ceased active work, to be revived again, however, by the Ruskin Union, formed in the year of the writer's death (1900). The Home Arts and Industries Association continues a work which was started in 1884, and anticipated much of the present system of technical education.

Societies of Special Study, Practice and Protection.—Under this head should be placed those associations which affect a cult, or are composed of particular workers, or which protect public or private interests. The most important of these is a society which has never yet held an exhibition, the Royal Society of British Sculptors (1904). The Blake Society and the Wren Society throw further light on the work of the great seer and the great architect. The Vasari Society, founded in 1905, carries on the work of reproducing drawings by the old masters. In this category of special study may also be placed the Egypt Exploration Society and the Society for the Promotion of Hellenic Studies. The number of societies devoted to the art of engraving and lithography in their various forms prove unfounded the old fear that photographic processes would cause these graphic arts to become extinct. As an instance of the tendency of art workers to combine, the National Society of Art Masters is a good illustration. This is an association of teachers of art schools, controlled by the art branch of the Board of Education, and has a membership of over 300. Good work of another kind occupies the National Trust for Places of Historic Interest or Natural Beauty. The council of the trust includes 25 representatives of such bodies as the National Gallery, the Royal Academy, the Royal Society of Painters in Water Colours, the Society of Antiquaries, the Royal Institute of British Architects, the Universities, Society for the Protection of Ancient Buildings and the Selborne Society. (X.)

THE UNITED STATES

In the United States there are more than 600 art societies and associations, not counting endowed institutions or art schools, or even art departments of clubs organized for social or general educational purposes. Of this number nearly 200 are professional organizations—painters, sculptors, architects, craftsmen banded together for mutual benefit and the advancement of their art; 40 or more are associations, chiefly of laymen, sponsoring and directing the development of art galleries or museums; the remainder, and the majority, are organizations composed of laymen who have come together to spread knowledge and appreciation of art either locally or throughout the country. Of each kind of organization described in this article there are not one or two but many, yet almost all of the 600 and more will be found to fall naturally into one or another of these types.

The oldest art association in the United States is the Pennsylvania Academy of the Fine Arts, which was established in Philadelphia in 1805 to provide instruction in the fine arts, exhibit works of contemporary artists and maintain a permanent collection and gallery. An Academy of Sciences and Fine Arts had been formed in Richmond, Va., in 1786, but the project had languished and finally been dropped. The New York Academy of the Fine Arts was organized in New York City in 1802; it existed until 1841 and is said to have provided almost the only art influence in New York City for nearly a quarter of a century. In 1825, however, a number of its students formed the New York Drawing Association, an independent society presided over by the painter-inventor Samuel F. B. Morse, which in 1828 was incorporated as the National Academy of Design.

The development of interest in art in the United States has been progressive, for the first 100 years undoubtedly slow, but during the last 50 more rapid, and during the last 20 surprisingly so. It may well be noted that the art movement has been largely fostered by laymen. In 1909 the American Federation of Arts was formed to furnish a channel for the expression of public opinion in matters pertaining to art, to maintain a central clearing house for art organizations throughout the country and to undertake educational work for which only a national organization could qualify; with headquarters at Washington, D.C., it now has more than 400 art associations and museums affiliated with it. To have a central organization, art associations in some states have federated. The Southern States Art League is pledged to the development of art in the South.

Professional Organizations.—Chartered in 1857, the American Institute of Architects, Washington, D. C., has held annual conventions since 1867; its membership of 3,250, included in 58 chapters, is entirely professional. Other architectural organizations include the Society of Beaux-Arts Architects (1874), 272 members; the American Group of the *Société des Architects Diplômés par le Gouvernement Français* (1899), 85 members; and such local societies as the T Square Club of Philadelphia (1888), 400 members. The Archaeological Institute of America (1879), with headquarters in Washington and 46 affiliated societies, is intended to increase knowledge and disseminate information in its field.

The National Academy of Design, already mentioned, elects to membership painters, sculptors and architects who have attained distinction, holds two exhibitions a season and maintains a permanent collection of works by members, of which there are now 293, and a school. The National Sculpture Society, New York, 372 members, was organized in 1893 to advance sculpture and the welfare of American sculptors. In its field, the Mural Painters, New York (1895), is similar. The American Water Color Society, New York (1850), holds annual exhibitions jointly with the New York Water Color Club (1890). Equally important is the Philadelphia Water Color Club (1900), whose annual exhibitions are usually in association with the Pennsylvania Society of Miniature Painters (1901). Boston, Baltimore, Washington and other cities also have well established water-colour clubs. The American Society of Miniature Painters, New York (1899), 31 members, exhibits regularly, and similar societies are active in Chicago and in California. In recent years etching, lithography and wood-block printing have had a renaissance in the United States. The Chicago Society of Etchers (1910), comprising 485 professional and lay members, holds and circulates exhibitions, gives demonstrations and has established a fund for purchase of works exhibited. The Print Makers' Society of California (1914), 310 members, is similar but holds an annual international exhibition of prints. Other societies of a like nature include the Brooklyn Society of Etchers (1915), 489 members; the Print Club of Philadelphia (1914), 678 members, which holds exhibitions of prints every two weeks during the season, has a press and gives lectures and demonstrations open to the public; and the Print Club of Cleveland (1919), 221 members. The Architectural League of New York (1881), 850 members, includes not only architects but painters, sculptors, craftsmen and workers in the allied arts; it holds annual exhibitions and encourages a close alliance of the arts, both fine and industrial.

To further literature and the fine arts, the American Social Science Association organized in 1898 a National Institute of Arts and Letters, New York, which was incorporated by Act of Con-

gress in 1913. It comprises, by election, 250 writers, painters, sculptors, etchers, etc. In 1904 it organized an American Academy of Arts and Letters, New York, limited to 50 members. The American Academy of Arts and Letters, was organized, obviously, along lines similar to the French Academy.

An organization to advance the artist as well as his art is the Guild of Boston Artists (1914), with 77 artist and 600 associate lay members co-operating in sustaining a gallery for exhibition and sale of members' works. Somewhat similar, the Grand Central Art Galleries, New York (1923), with the frank purpose of marketing works of American artists, maintains a continuous exhibition of works of members and also sends out travelling exhibitions. The Société Anonyme, New York City, was founded in 1920 by Marcel Duchamp and Katherine S. Dreier. Its aim is to promote *art progressive* in all its branches. Its first International Exhibition represented 23 countries.

The alumni associations of the leading art schools are closely allied with the professional art organizations. Examples of these are the Fellowship of the Pennsylvania Academy of the Fine Arts, Philadelphia (1897), 800 members; and the Alumni Association of the Art Institute of Chicago (1912), more than 1,000 members; the Art Students' League, New York (1875). (*See* SCHOOLS OF ART.)

Groups Associated with Museums.—Reference has been made to the development of art museums through the instrumentality of art associations. The individual members of the Metropolitan Museum of Art, New York, now number more than 13,250. The Museum of Fine Arts, Boston, formed in the same year (1870) as the Metropolitan Museum, likewise depends to a great extent on its supporting membership, while the Art Institute of Chicago (1879), more than 17,000 members, is essentially a people's institution. The Toledo Museum of Art (1901) was long supported by an associate membership; the Buffalo Fine Arts Academy (1862) is the parent of the Albright Art Gallery; the Cincinnati Museum Association (1881) acquired a gallery through gifts in 1887 and is still supported by private contribution; the Art Association of Indianapolis (1883), 919 members, acquired a gallery, now the John Herron Art Institute, in 1902; and the Minneapolis Society of Fine Arts (1883) erected in 1911 a building, now the Minneapolis Institute of Arts, with which the Friends of the Institute (1922) co-operate in building up its collections and broadening its influence. Various "Friends of Art" groups have been formed in recent years; perhaps the most notable is the Friends of American Art, Chicago (1910); the art department of the Carnegie Institute, Pittsburgh, has an auxiliary circle, Friends of Pittsburgh Art; the Baltimore Museum has the Friends of Art in Baltimore, and the municipally supported Detroit Institute of Art has an Art Founder's Society. The Newark Museum Association (1909) has 1,650 members. The Fine Arts Gallery of San Diego, Calif., is the child of the Fine Arts Society of San Diego (1925), 1,021 members. Art museum directors have organized in two groups: those east of the Rocky mountains in the Association of Art Museum Directors (1916), those on the Pacific coast in the Western Association of Museum Directors (1921). There is also a national organization, the American Association of Museums, Washington, D.C. (1907). (*See* MUSEUMS.)

Art and Industry.—Probably the first organization in the United States to recognize the need of relating art to industry was the Cooper Union, New York (1854). The handicrafts have largely been fostered by societies especially organized for that purpose, such as the Society of Arts and Crafts of Boston (1897), 1,350 members, which has set a high standard of endeavour and has maintained a sales room most successfully for many years in Boston and in recent years in New York. Similar, the Detroit Society of Arts and Crafts (1906), with over 1,000 lay and professional members, has brought to America notable works by foreign craftsmen. More intimately associated with industrial art are such organizations as the Association of Arts and Industries of Chicago, or the Art in Trades Club, New York (1906), made up of 525 men engaged in some form of art in industry. The Art Directors' Club, New York (1920), 200 members, is partly social but is intended to improve art products. The 175 members of the Business Men's Art Club of Chicago (1920) turn to art for recreation rather than as a vocation. The Graphic Sketch Club of Philadelphia is similar in purpose.

Civic Associations.—The American Civic Association (1904), a national organization with headquarters at Washington, D.C., and several hundred affiliated organizations throughout the country, embraces city planning, village improvement, protection of scenic beauty and safeguarding of highways in its objectives. Somewhat akin in purpose is the American Society of Landscape Architects (1899), 215 members, with headquarters in Boston, whose chief aim is the support of professional ideals in the practice of landscape architecture as an art, and whose concern is mostly that of design in city and regional planning and the design of private and institutional parks and grounds. There are also numerous art commissions such as, for example, the National Commission of Fine Arts, Washington, D.C. (1910), appointed by the President with the consent of Congress and comprising an advisory body of experts, serving without pay, to which are referred designs for public buildings, monuments, improvements of public lands, etc.; the Art Commission of the City of New York (1898) and the Art Jury, Philadelphia (1907), intended to safeguard municipal authorities against artistic blunders and secure the maximum beauty for their respective cities; the Municipal Art Society of New York (1892), 1,000 members, a private organization for the development of civic art; and the Community Arts Association of Santa Barbara, Calif. (1920), 1,200 members.

School Organizations.—Public school art teachers have banded together in three organizations: the Eastern Arts Association (1889), 2,000 members; the Western Arts Association (1893), 313 members; and the Art Teachers' Association of Southern California (1917), 150 members. The College Art Association of America (1912), 500 members, is made up of teachers of art in colleges. The purpose of the Federated Council on Art Education (1924) is to study current educational methods and report thereon, with the object of the advancement of art teaching in America. The School Art League of New York City (1911), composed of laymen, art teachers and pupils, fosters art education in the public schools of that city. The Chicago Public School Art Society (1894) is chiefly occupied with placing fine prints and paintings by American artists in Chicago schools but has also been instrumental in securing better design for school buildings and decoration for school rooms.

A complete list of art societies and similar organizations in the United States, together with a report on each, will be found in the American Art Annual, published by the American Federation of Arts. (L. ME.)

THE CONTINENT OF EUROPE

France.—Paris: The *Académie des beaux-arts* dates from 1795, when two academies founded successively by Mazarin and Colbert in 1671 united in a single society. It aims to establish a central meeting place for French and foreign architects, and foster the interests and progress of the profession of architecture. The *Société d'Encouragement à l'Art et à l'Industrie* was founded in 1889 and established as a "public utility" in 1925. The *Société des Architectes Diplômés par le Gouvernement*, founded in 1877 and established as a "public utility" in 1915, has about 1,500 members. The *Association Française des Artistes Graveurs au Burin* is a small but active organization whose object is to propagate the art of engraving. The *Union Centrale des Arts Décoratifs*, founded in 1880 and recognized as a "public utility" in 1882, has for its object the cultivation of those arts which strive to realize beauty in useful things. The *Salon des Tuileries au Palais de Bois* was founded in 1923, and every year invites about 1,000 artists to exhibit. The *Société des Amis du Louvre* endeavours to bring into one association all who are devoted to the Louvre, with a view of enriching its collections.

Germany.—Berlin: The small local societies are affiliated with one large parent body, the *Deutsche Künstlergenossenschaft* in Berlin. The *Deutscher Illustratorenverband* watches over the interests of illustrators and designers. The *Verband Deutscher Architekten- und Ingenieur-Vereine E.V.*, founded in 1871, has

a membership of 8,000 and is very active. The *Deutscher Werkbund,* with a membership of 2,600, has for its aim the ennoblement of craftsmanship in the association of art with industry. The *Reichsverband bildender Künstler Deutschlands* secures representation through one united organization of the artists of Germany in their professional and social interests. It had a membership in 1928 of 8,760, and publishes *Kunst und Wirtschaft.* The *Allgemeine Deutsche Kunstgenossenschaft* has exhibitions at home and abroad. It was founded in 1856 and in 1928 had 500 members. The *Bund Deutscher Architekten,* Frankfort, had 2,764 members in 1928.

Austria.—Vienna: The *Vereinigung bildender Künstler Österreichs* (Society of Austrian Artists) and the *Wiener Künstlergenossenschaft* (Association of Viennese Artists) are prominent.

Belgium:—Brussels: The *Palais des Beaux-Arts de Bruxelles* is the centre of the artistic movement in Belgium and the surrounding countries, Brussels being only a few hours' journey from Paris, London, Amsterdam and Frankfort. During 1928 it held over 50 exhibitions, numerous meetings, concerts, etc. The building was finished in 1926. The *Société des Amis des Musées Royaux de l'État à Bruxelles,* founded in 1907, has about 300 members. Its primary object is to enrich the collections of the museums of the country. The *Société Centrale d'Architecture de Belgique* was organized under the *Union Professionelle* in 1872. It has a membership of about 300.

Scandinavia.—In Stockholm (Sweden) the *Svenska Slöjdföreningen* had 2,800 members in 1928. The *Kungl. Akademien för de fria Konsterna* (The Royal Academy of Fine Arts), founded in 1735, has control of the Royal High School of Art. The *Konstantverkarnas Gille,* founded in 1906, has for its object the promotion of handicraft and the friendly co-existence between handicraftsmen. The *Föreningen för grofisk konst* supports the graphic arts, and the *Föreningen Original-Fräsnitt* interests the public in the art of wood-engraving. Other art societies of Stockholm are the *Svenska Teknologföreningen,* the *Konsthistoriska Sällskapet,* the *Sveriges Allmänna Konstförening,* and the *Svenska Hemslöjdföreningarnas Riksförbund.* In Copenhagen (Denmark) the *Künstnerföreningen* is the outstanding art society.

Italy.—A few of the many organizations interested in the arts are listed. Rome: *Società "In Arte Libertas"; Associazione Internazionale Artistica; Associazione Artistica fra i cultori d'Architectura; Associazione Archeologica Romana; Società degli Amatori e Cultori di Belle Arti; Società degli Acquarellisti; Società Archeologica Anglo-Americana.* Florence: *Associazione Nazionale degli Artisti; Società Artistica; Società Fiorentina per le Sculture artistiche; R. Accademia di Belle Arti.* Bologna: *Comitato per Bologna Storico-Artistica; R. Sopraintendenza alle Belle Arti dell' Emilia: R. Accademia di Belle Arti; Bottega d'arte.* Naples: *Circolo Numismatico Napoletano; R. Accademia di Archeologia Lettere e Belle Arti;* Genoa: *Società di Belle Arti; Società Promotrice di Belle Arti; Società Alere Flamman; Circolo Artistico "Tunnel."* Milan: *Società Italiana di Numismatica; R. Accademia di Belle Arti.*

Other European Countries.—The following societies of art are among the more important: Amsterdam (Holland), *Maatschappij "Arti et Amicitiae";* Budapest (Hungary), the Society of Hungarian Painters and Etchers; Warsaw (Poland), the *Société des Beaux Arts à Varsovie;* Berne (Switzerland), *La Société des Peintres et Sculpteurs Suisses;* Madrid (Spain), *L'Association des Artistes Espagnols;* Lisbon (Portugal), *Sociedade Nacionale de Bellas Artes y Gremio Artistico.*

THE ORIENT

The oldest society dealing with oriental archaeology is claimed to be the *Kon. Bataviaasch Genootschap van Kunsten en Wetenschappen,* Java, founded in 1778, closely followed by the Asiatic Society of Bengal in 1784. In England, the Royal Asiatic Society (1823) has branches in many places in Asia, and also in Canada.

The following societies are the most important in Europe: London: The Royal Asiatic Society (1823) with 950 members and a library of 30,000 volumes, and the India Society (1910), with 350 members; Paris: the *Association Française des Amis de l'Orient* (1920); The Hague: the *Vereenigung van Vrienden der Aziatische Kunst* (1918); Berlin: the *Gesellschaft für Ostasiatische Kunst* (1926); Vienna: the *Verein der Freunde Asiatischer Kunst und Kultur* (1920); Rome: the *Istituto per l'Oriente* (1921); Budapest, Stockholm, Oslo, and Copenhagen have small but active societies.

Other societies interested in the art of the Far East are: the Royal Asiatic Society with the Bombay Branch at Bombay, the Ceylon Branch at Colombo, and the Malayan Branch at Singapore; the Indian Society of Oriental Art (1907), Calcutta; the Mythic Society (1909), Bangalore; the Burma Research Society (1910), Burma; the Punjab Historical Society (1910), Lahore; the Hyderabad Archaeological Society (1915), Hyderabad; and the Bihar and Orissa Research Society, Patna. (*See* INDIAN AND SINHALESE ART AND ARCHAEOLOGY.) (X.)

China.—Temperamentally, the Chinese, especially the highly educated, are not much given to organization (*see* CHINA, *Aesthetic Development*). Consequently in history we hear very little of artistic activity in any organized sense.

The National University of Peking is almost solely responsible for both the moral and intellectual forces now at work in the whole of China. The university faculty is undoubtedly the greatest literary and art society that China has ever known. There are, however, three or four literary and art groups that are perhaps better organized than the faculty group. The Literary Society of China, whose motto is "Art for Life's Sake," has found opposition in another group known as the Creation Society, who started the "art for art" movement in China. A serious effort at regenerating the Chinese culture is represented by another group, The Crescent Moon Society, which was organized in Peking in 1923. Among other things in art, it has produced plays by Ibsen, Shaw, Maeterlinck, Tagore and Eugene O'Neill, as well as the Chinese writers. The *Nan-Kuo* group may be described as representing the Bohemian spirit of young China.

There are innumerable art clubs and societies both in Peking and Shanghai and other cities. The most notable one is the "Pegasus Society" of Shanghai, which has a large membership of artists of the traditional type as well as returned students of art from Western countries. It holds annual exhibitions. The Royal Asiatic Society, North China Branch, Shanghai (1857), has 604 members, possesses a library and museum, publishes a journal and has issued five volumes. (*See* CHINESE ART.)

(T. Hs.; Y. K.)

Korea.—The art of Korea, like that of her great neighbour, China, has always been the product of the leisured class. When Korea's civilization was at its height during the Korai period (10th–14th centuries), literary groups and art societies centered their efforts around Buddhistic culture. The artistic activities of the Buddhists have been carried on in mountain solitudes since the monks were compelled to take refuge there in the 15th century. In 1909, the Chosen Yunkoo Society was established for the purpose of excavating ancient monuments and gathering old prints and fine examples of calligraphy. With the support of the Chosen Government, it has collected about 150,000 prints and specimens. In 1909–15 the members of the Chosen Yunkoo Society made an investigation of the historical monuments. The Korean Art Society was founded in 1922 also under the supervision of the Chosen Government, holding the annual exhibition in Seoul. The Chosen Moondan Society was founded in 1924 in Seoul to spread the doctrine of "Art for Life's Sake," and when it discontinued, the Kaipyuk took its place; it now represents the Bohemian spirit of young Korea. *Kwang Chang Hoi* is a society of artists in Western style, holding annual exhibitions. The *Suwha Yunkoo Hoi,* another society in traditional style, to stimulate calligraphers and painters, develops its work through the Four Sages: the plum, lily, chrysanthemum and bamboo. There are many private societies. (Y. K.)

Japan.—The Japanese are clever in adapting other civilizations to suit their own tastes and needs. This is particularly true in the realm of art, and its various societies. When Buddhism came from Korea in the 6th century, Chinese ideographs and

calligraphy, which included painting, were introduced. Ever since, the Japanese have had art groups, schools or societies—such as the *Yamato* and *Toza* of the 11th century, Kano, founded by Kano Monotobu (1476–1559); *Ukiyoye,* by Iwasa Matahei (1577–1650); *Korin,* following the style of Koyetsu (1552–1637); and *Shijo,* imitating the naturalistic school of Okyo (1733–95). (*See* also JAPANESE PAINTING AND PRINTS.)

The Imperial Art Institute (Teikoku Bijutsu-In), Tokyo, begun under the auspices of the Department of Education in 1907, was modified in 1919, and in 1927 a section of applied arts was added to those of painting and sculpture; exhibitions are held. The National Treasure Preservation Commission (1897) examines treasures in Shinto shrines and Buddhist temples and schedules for State protection paintings, calligraphs, sculpture, buildings, old documents of historical value, armour and weapons, and examples of handicraft. The Fine Arts Association of Japan (*Nihon Bijutsu Kyokai*), Tokyo, was established in 1879 to stimulate art. It arranged a Japanese art exhibition in Paris in 1883. It has over 1,000 members, has always adhered to the old ideals of Japanese art and holds exhibitions. The Japan Art Institute (*Nihon Bijutsu-In*), Tokyo, 1897, conducts a studio, with classes in painting in the traditional style, and in sculpture. *Nika-Kai,* Tokyo, an association of painters in Western style, was organized in 1908 in defiance of the "classical narrowness" of the annual art exhibition then held under the Department of Education. Besides these mentioned above, Tokyo has many other important societies.

Kyoto has a number of societies of art, such as the Fine Arts Association (*Kyoto Bijutsu Kyokai*), Creative National Painting Association (*Kokuga Sosaku Kyokai*), Institute of Painters of the Southern School (*Nihon Nanga-In*).

Osaka has the Art Association of the city of Osaka (*Osakash: Bijutsu Kyokai*) and the Osaka Art Club (*Osaka Bijutsu Kurabu*). (J. HAR.; Y. K.)

SOCIETY ISLANDS: *see* PACIFIC ISLANDS.

SOCIETY OF THE CINCINNATI, an organization formed by the officers of the American Revolutionary Army in May, 1783, a few weeks before the army's disbandment, for the purposes of promoting friendship and union, of cherishing the memory of events through which they had passed, and of aiding members and their families in case of need. Suggestion of such an association is credited to Major General Henry Knox (*q.v.*) and its formation took place at the headquarters of Baron von Steuben near Fishkill Landing, N.Y. George Washington was chosen the first president and remained in that office until his death. State societies, auxiliary to the general society, were formed in the 13 states and a branch was also formed in France. The badge, a golden eagle, suspended by a ribbon, contained in its center a device representing Cincinnatus at his plough receiving the Roman senators who came to offer him a sword. The constitution provided that, in case of death of a member, the eldest male descendant was entitled to wear the badge and enjoy the privileges of the society. In failure of direct male descent the honour passed to male descendants through intervening female descendants, and in case of their failure to collateral descendants judged worthy of becoming members. This hereditary provision aroused opposition for a time from those, especially anti-Federalists, who feared it would result in the creation of an hereditary nobility which would assume to itself political and military offices. The fear, easily understood, did not prove justified by subsequent events, for with the death of the officers themselves the society all but died out, most of the state auxiliaries passing entirely out of existence. Toward the close of the 19th century the society was revived by eligible descendants, and, by 1902, the last of the original 13 state auxiliaries was reconstituted. The state auxiliaries now hold annual meetings and the general society a meeting every three years. The number of members reported at the triennial meeting in 1926 was 1,047.

Proceedings of the state auxiliaries and the general society are issued after each meeting. *See* also A. H. Mattox, *History of the Cincinnati Society* (1880), and F. A. Foster, *The Institution of the Society of the Cincinnati* (1923).

SOCINUS, the latinized form of the Italian Sozini, Sozzini or Soccini, a name borne by two Italian theologians of the sixteenth and seventeenth centuries.

I. LELIO FRANCESCO MARIA SOZINI (1525–1562) was born at Siena on Jan. 29, 1525. His family descended from Sozzo, a banker at Percena, whose second son, Mino Sozzi, settled as a notary at Siena in 1304. Mino Sozzi's grandson, Sozzino (d. 1403), was ancestor of a line of patrician jurists and canonists, Mariano Sozzini senior (1397–1467) being the first and the most famous, and traditionally regarded as the first freethinker in the family. Lelio (who spells his surname Sozini, latinizing it Sozinus) was the sixth son of Mariano Sozzini junior (1482–1556) by his wife Camilla Salvetti, and was educated as a jurist under his father's eye at Bologna. He told Melanchthon that his desire to reach the *fontes iuris* led him to biblical research, and hence to rejection of "the idolatry of Rome." At Chiavenna in 1547 Sozini came under the influence of Camillo of Sicily, a gentle mystic, surnamed Renato, whose teaching at many points resembled that of the early Quakers. He travelled in Switzerland, France, England and Holland. Returning to Switzerland at the close of 1548, with commendatory letters to the Swiss churches from Nicolas Meyer, envoy from Wittenberg to Italy, we find him (1549–50) at Geneva, Basle (with Sebastian Münster) and Zürich (lodging with Pellican). He is next in Wittenberg (July 1550 to June 1551), first as Melanchthon's guest, then with Johann Forster for improvement of his Hebrew. From Wittenberg he returned to Zürich (end of 1551), after visiting Prague, Vienna and Cracow. Political events drew him back to Italy in June 1552; two visits to Siena (where freedom of speech was for the moment possible, owing to the shaking off of the Spanish yoke) brought him into fruitful contact with his young nephew Fausto. He was at Padua (not Geneva, as is often said) at the date of Servetus's execution (Oct. 27, 1553). Thence he made his way to Basle (Jan. 1554), Geneva (April) and Zürich (May), where he, eventually, took up his residence.

Of the Reformers, Bullinger was Sozini's closest intimate, his warmest and wisest friend. Sozini's theological difficulties turned on the resurrection of the body, predestination, the ground of salvation (on these points he corresponded with Calvin), the doctrinal basis of the original gospel (his queries to Bullinger), the nature of repentance (to Rudolph Gualther), the sacraments (to Johann Wolff). The fate of Servetus directed his mind to the problem of the Trinity. At Geneva (April 1554) he made incautious remarks on the common doctrine, emphasized in a subsequent letter to Martinengo, the Italian pastor. Bullinger, at the instance of correspondents (including Calvin), questioned Sozini as to his faith, and received from him an explicitly orthodox confession (reduced to writing on July 15, 1555) with a frank reservation of the right of further enquiry. A month before this Sozini had been sent with Martino Muralto to Basle, to secure Ochino as pastor of the Italian church at Zürich; and it is clear that the minds of Sozini and Ochino acted powerfully on each other.

In 1556, by the death of his father, Sozini was involved in pecuniary anxieties. He visited in 1558 the courts of Vienna and Cracow to obtain support for an appeal to the reigning duke at Florence for the realization of his own and the family estates. Sozini did not proceed beyond Venice. The Inquisition had its eye on the family; his brother Cornelio was imprisoned at Rome; his brothers Celso and Camillo and his nephew Fausto were "reputati Luterani," and Camillo had fled from Siena. In Aug. 1559 Sozini returned to Zürich, where he died on May 14, 1562.

Sozini's extant writings are: (1) *De sacramentis dissertatio* (1560), four parts, and (2) *De resurrectione* (a fragment); these were first printed in *F. et L. Socini, item E. Soneri tractatus* (Amsterdam, 1654). To these may be added his *Confession* (1555), printed in Hottinger, *Hist. eccles. N.T.* ix. 16, 5 (1667); and about 24 letters, not collected, but may be found dispersed, and more or less correctly given in Illgen, in Trechsel, in the *Corpus reformatorum* edition of Calvin's works, and in E. Burnat, *L. Socin* (1894); the handwriting of the originals is exceedingly crabbed. Sand adds a *Rhapsodia in Esaiam prophetam,* of which nothing is known. Beza suspected that Sozini had a hand in the *De haereticis, an sint persequendi* (1553); and to him has also been assigned the *Contra libellum Calvini* (1554); both are the work of Castellio, and there is no ground for attributing any part of them to

Sozini. Beza also assigned to him (in 1567) an anonymous *Explicatio* (1562) of the proem of St. John's Gospel, which was the work of Fausto; this error, adopted by Zanchi, has been a chief source of the misconception which treats Lelio as a heresiarch. In Franc Guinio's *Defensio cath. doct. de S. Trin.* (1590–91) is an anonymous *enumeratio* of motives for professing the doctrine of the Trinity, by some ascribed to Lelio; by others, with somewhat more probability, to Fausto.

For the life of L. Sozini the best guide is Trechsel, *Die prot. antitrin. vor F. Socin*, vol. ii. (1844); but there are valuable materials in Illgen, *Vita L. Socini* (1814), and especially *Symbolae ad vitam et doctrinam L. Soc.*, etc. (1826). R. Wallace, *Antitrin. biog.* (1850), gives the ordinary Unitarian view, relying on Bock, Da Porta and Lubieniecki. *See* also *Theological Review* (July 1879), and Bonet-Maury, *Early Sources of Eng. Unit. Christ.* (trans. E. P. Hall, 1884). Use has been made above of unprinted sources.

II. Fausto Paolo Sozzini (1539–1604) was born at Siena on Dec. 5, 1539, the only son of Alessandro Sozzini, "princeps subtilitatum," by Agnese, daughter of Borghese Petrucci, a descendant of Pandolfo Petrucci, the Cromwell of Siena. Unlike his uncle Lelio, Fausto spells his surname Sozzini, latinizing it Socinus. His father died in 1541. Fausto had no regular education, being brought up at home with his sister Fillide, and spent his youth in desultory reading at Scopeto, the family country-seat. His early intellectual stimulus came from his uncle Celso, a nominal Catholic, but an *esprit fort*, founder of the short-lived *Accademia dei Sizienti* (1554), of which Fausto was a member. In 1561 he went to Lyons, probably engaging in mercantile business; he revisited Italy after his uncle Lelio's death; we find him in 1562 on the roll of the Italian church at Geneva; there is no trace of any relations with Calvin; to Lyons he returned next year. The evangelical position was not radical enough for him. In his *Explicatio* (1562) of the proem to St. John's Gospel he already attributes to Christ an official, not an essential, deity; a letter of 1563 rejects the natural immortality of man (a position subsequently developed in his disputation with Pucci). Towards the end of 1563 he returned to Italy, conforming to the Catholic Church, and for 12 years was in the service of Isabella de Medici, daughter of the grand-duke Cosimo of Tuscany. At the instance of "a great personage" he wrote (1570) his treatise *De auctoritate s. scripturae*. In 1571 he was in Rome, probably with his patroness. He left Italy at the end of 1575, and after the murder of Isabella he declined the invitation of her brother Francesco, now grand-duke, to return. Sozzini now settled at Basle, began translating the Psalms into Italian verse, and became a centre of theological debates. His discussion with Jacques Couet on the doctrine of salvation issued in a treatise *De Jesu Christo servatore* (finished July 12, 1578), which was read in manuscript by Giorgio Blandrata (*q.v.*), court physician in Poland and Transylvania.

Transylvania had for a short time (1559–71) enjoyed full religious liberty under an anti-Trinitarian prince, John Sigismund. The existing ruler, Christopher Báthori, favoured the Jesuits; it was now Blandrata's object to limit the "Judaic" tendencies of the eloquent anti-Trinitarian bishop, Francis Dávid (1510–79), and he called in Sozzini to reason with Dávid, who had renounced the worship of Christ. Sozzini used terms in themselves orthodox in a heretical sense. Thus Christ was God, though in nature purely human, namely as *un Dio subalterno, al quale in un dato tempo il Dio supremo cedette il governo del mondo* (Cantù). In matter of worship Sozzini distinguished between *adoratio Christi*, the homage of the heart, imperative on all Christians, and *invocatio Christi*, the direct address of prayer, which was simply permissive; though in Sozzini's view, prayer, to whomsoever addressed, was received by Christ as mediator, for transmission to the Father.

In Nov. 1578 Sozzini reached Kolozsvár (Klausenburg) from Poland, and, during a visit of four months and a half under Dávid's roof, tried to persuade him to adopt this modified doctrine of invocation. The upshot was that Dávid from the pulpit exerted all his powers in denouncing all cultus of Christ. His civil trial followed, on a charge of innovation. Sozzini hurried back to Poland before it began. He cannot be accused of complicity with what he calls the rage of Blandrata; he was no party to Dávid's incarceration at Déva, where the old man miserably perished in less than three months. But his references to the case show that theological aversions froze up his native kindness and blinded his perceptions of character.

The remainder (1579–1604) of Sozzini's life was spent in Poland. Excluded at first by his views on baptism (which he regarded as applicable only to Gentile converts) from the Minor or anti-Trinitarian Church (largely anabaptist), he acquired by degrees a predominant influence in its synods. He converted the Arians from their avowal of Christ's pre-existence, and from their rejection of the *invocatio Christi;* he repressed the semi-Judaizers whom he failed to convince. Through correspondence with friends he directed also the policy of the anti-Trinitarian Church of Transylvania. Forced to leave Cracow in 1583, he found a home with a Polish noble, Christopher Morsztyn, whose daughter Elizabeth he married (1586). In Oct. 1590 the Holy Office at Siena disinherited him, allowing him a pension, apparently never paid. He now began to publish in his own name, with the result that in 1598 a mob finally expelled him from Cracow. He died at Luslawice on March 4, 1604.

His treatise on the Saviour renders a real service to theology, placing orthodoxy and heresy in new relations of fundamental antagonism, and narrowing the conflict to the main personal benefit of religion. Of the person of Christ in this treatise he says nothing; its one topic is the work of Christ, which in his view operates upon man alone; the theological sagacity of Sozzini may be measured by the persistency with which this idea tends to recur. Though his name has been attached to a school of opinion, he disclaimed the rôle of a heresiarch, and declined to give his unreserved adhesion to any one sect. His confidence in the conclusions of his own mind has earned him the repute of a dogmatist; but it was his constant aim to reduce and simplify the fundamentals of Christianity. Not without some ground does the memorial tablet at Siena (inscription by Brigidi, 1879) characterize him as vindicator of human reason against the supernatural. Of his non-theological doctrines the most important is his assertion of the unlawfulness not only of war, but of the taking of human life in any circumstances. Hence the comparative mildness of his proposals for dealing with religious and anti-religious offenders, though it cannot be said that he had grasped the complete theory of toleration. Hence, too, his contention that magisterial office is unlawful for a Christian.

Sozzini's works, edited by his grandson Andrew Wiszowaty and the learned printer F. Kuyper, are contained in two closely printed folios (Amsterdam, 1668). They rank as the first two volumes of the *Bibliotheca fratrum polonorum*, though the works of Crell and Schlichting were the first of the series to be printed. They include all Sozzini's extant theological writings, except his essay on predestination (in which he denies that God foresees the actions of free agents) prefixed to Castellio's *Dialogi IV*. (1578, reprinted 1613) and his revision of a school manual *Instrumentum doctrinarum aristotelicum* (1586). His pseudonyms, easily interpreted, were Felix Turpio Urbevetanus, Prosper Dysidaeus, Gratianus Prosper and Gratianus Turpio Gerapolensis (=Senensis). Some of his early verse is in Ferentilli's *Scielta di stanze di diversi autori toscani* (1579, 1594); other specimens are given in Cantù and in the *Athenaeum* (Aug. 11, 1877); more are preserved at Siena. Sozzini considered that his ablest work was his *Contra atheos*, which perished in the riot at Cracow (1598). Later he began, but left incomplete, more than one work designed to exhibit his system as a whole. His reputation as a thinker must rest upon (1) his *De auctoritate s. scripturae* (1570) and (2) his *De Jesu Christo servatore* (1578). The former was first published (Seville, 1588) by Lopez, a Jesuit, who claimed it as his own, but prefixed a preface maintaining (contrary to a fundamental position of Sozzini) that man by nature has a knowledge of God. A French version (1592) was approved by the ministers of Basle; the English translation by Edward Coombe (1731) was undertaken in consequence of the commendation in a charge (1728) by Bishop Smalbroke, who observes that Grotius had borrowed from it in his *De veritate Christ. rel.* In small compass his *De auctoritate s. scripturae* anticipates the historical argument of the "credibility" writers; in trying it by modern tests, it should be remembered that Sozzini, regarding it (1581) as not adequately meeting the cardinal difficulties attending the proof of the Christian religion, began to reconstruct its positions in his *Lectiones sacrae* (unfinished).

For the biography of Sozzini the best materials are his letters; a collection is in his works; others are given by Cantù; more are preserved at Siena and Florence; his correspondence is open and frank, never sparing his weak points. The earliest life (prefixed to his works) is by S. Przypkowski (1636); in English, by J. Bidle (1653). This is the foundation of the article by Bayle, the *Memoirs* by J. Toulmin (1777), and the article by R. Wallace (*Antitrin. Biog.*, 1850). Cantù's sketch in *Gli Eretici d'Italia* (1866) gives a genealogy of the Sozzini.

(A. Go.; X.)

SOCIOLOGICAL SOCIETIES. The societies listed below are those of the widest appeal in sociology and allied subjects. Allied subjects (Economic Science, Statistics, Law and Education) are included and the chief institutions for research into these subjects will be found below.

The international societies are the *Association Internationale pour le Progrès des Sciences Sociales* and the *Congrès International de Statistique,* which first met at Brussels in 1853. Both have issued *Comptes rendus.* The *Inst. Internat. de Sociologie* (1893) has its headquarters at Paris. The *National Association for the Promotion of Social Science* (1857) had united with it in 1864 the *Society for Promoting the Amendment of the Law.* It held a yearly migratory meeting, and published *Transactions* (1858, etc.) and *Social Science* (1866, etc.). The *Sociological Soc.,* the *Eugenics Education Soc.* and the *Roy. Economic Soc.* are established in London. The *Royal Statistical Society* (1834), incorporated 1887, publishes a *Journal* (1839, etc.); *Cobden Club* (1866), for the diffusion of the political and economical principles with which Cobden's name is associated, has issued a variety of publications; *Institute of Actuaries* (incorp. 1884); *Institute of Chartered Accountants* (1880); *Institute of Bankers* (1879); the *Society of Incorporated Accountants and Auditors* (1885), and the *Chartered Institute of Secretaries,* also meet in London. There are also the *Manchester Statistical Society* (1833), with *Transactions;* the *Faculty of Actuaries in Scotland* and the *Scottish Society of Economists* (1897), both meeting at Edinburgh; and the *Statistical and Social Inquiry Society of Ireland* (1847), with a *Journal,* at Dublin. After the INNS OF COURT (*q.v.*), the most important of British legal societies is the *Law Society* (1827, incorporated 1832, reincorp. 1845); it began courses of lectures for students in 1833, and was appointed registrar of solicitors ten years later, and obtained supplementary charters in 1845 and 1878. The *Selden Society,* established in 1887 for the promotion of the study of the history of law, prints ancient records. The headquarters of the *Association for the Reform and Codification of the Law of Nations* are in London, but conferences are held in various continental towns. The *Chartered Institute of Patent Agents* (founded 1882, incorporated 1891) issues *Transactions.* The *Juridical Society of Edinburgh* (1773) published five editions of a *Complete System of Conveyancing.* The *Ascham Society* was founded in 1879 for the improvement of educational methods; and the *Society for the Development of the Science of Education* (1875) issued *Transactions.*

SOCIOLOGY. The word was introduced in 1837 by Auguste Comte in the lectures which resulted in the publication of his "Positive Philosophy." Comte's intention in introducing the word has been widely misunderstood. It has been confused with the suggestions of practical change in polity and in religion, which, in the later part of his life, he advocated.

COMTE, HIS PREDECESSORS AND SUCCESSORS

The circumstances out of which the word and the idea arose are these. Comte considered himself to be in succession with a line of thinkers historically beginning with Thales and Pythagoras, continuing with Bacon and Descartes, and culminating in Hume's "Treatise of Human Nature," which attempted to unify and evaluate the total available knowledge of Man. Between the publication of Hume's "Treatise" in 1739 and Comte's attempt at a fresh synthesis, almost exactly a century intervened. It was a century in which the range of verifiable knowledge was enormously extended in all departments of investigation. It was a period of immense activity, analytic and synthetic, in the mathematical and physical sciences—witness the names of Fourier, Lagrange and Laplace, of Carnot, Coulomb and Volta, of Scheele, Lavoisier, Cavendish, Davy, Berthollet and Dalton. But as affecting the genesis of sociology, the main features of the century were, in the first place, the creation of the Biological Sciences as definite systems of study, and in the second place the growth of the conception of a Science of History. In whole or in part belong to this period the labours of Linnaeus, Haller and Jussieu, of Buffon and Cuvier; and finally, the attempt of Bichat, of Lamarck and of Treviranus to institute a general science of the phenomena of life, for which both the latter used the title Biology. The idea of a science of Human History, if it belongs to any individual, belongs to Vico, who held that he had established it by his "New Science" in 1725. This idea, in the interval between Hume's "Treatise," and Comte's "Positive Philosophy," had been notably developed by Montesquieu, Turgot, Condorcet and Saint-Simon, by Lessing, Herder and Kant, by Adam Smith, Ferguson and Millar.

Comte's Aim.—The immediate task which Comte proposed to himself was to survey with the eye of philosophy the scientific and historical labours of this prolific century intervening between Hume and himself. His attempted unification was propounded under the name of the Positive Philosophy, and, for that portion of the Positive Philosophy which set forth the bearing of the new scientific and historical knowledge on the conceptions of Human Nature and Society, he proposed the name sociology.

Between Vico's "New Science" and Comte's "Sociology," the infiltration of the phrase social science marks a general tendency towards the expansion of science into the field of humanistic studies. Among Comte's contemporaries J. S. Mill (only eight years younger than Comte) declared (in 1836) that the time was ripe for marking off from other studies—both scientific and philosophical—a general social science, and for this he used such phrases as Social Philosophy, Social Science, Natural History of Society, Speculative Politics and Social Economy. After the appearance of the "Positive Philosophy," Mill abandoned both the phrases he had previously recommended as being the most

suitable titles—Social Economy and Speculative Politics. He even denied to the latter any right to exist as a separate department of scientific studies. The word sociology he sanctioned by frequent use in the final book of his "Logic"; that "On the Logic of the Moral Sciences."

Herbert Spencer.—For a long time the word sociology made little headway, and this notwithstanding Mill's sanction and usage of it, and the rapid acquisition and long maintenance by his "Logic," of classic rank throughout the western world; carrying as it did the new term into quarters—notably in Germany and America—where the "Positive Philosophy" did not penetrate. It was not in fact till more than half a century had passed, that the word could be said to be accepted as part of the international vocabulary of the learned world. To this end, Spencer contributed much by his book "The Study of Sociology," which won recognition in almost every civilized country during the two decades between 1870 and 1890. The first volume of Spencer's "Principles of Sociology" appeared in 1876 and the last in 1896. Though comparatively neglected by British universities, Spencer's sociological work has been extensively studied in German and still more in American universities. In France, too, Spencer's influence has tended to the dissemination of the idea and the word sociology; for he is there considered as a continuator of the philosophical and scientific work of Comte.

But the main sociological movement has issued from other origins than those of Comte and Spencer. The master idea, which animated alike the initiator of sociology and his chief continuator, was that of evolution. The evolutionary concept of an orderly development proceeding by discoverable "laws" was applied by Comte to the past, present and future of Western civilization, itself taken as the essential feature of man's activity. Spencer extended this evolutionary concept to other types of society than that of Western civilization; aiming indeed in his "Descriptive Sociology" (of which the volumes continue to be compiled and published under the terms of his testamentary dispositions) at a comprehensive account of every social type to be found on the earth.

Evolution in the Social Sciences.—Independently of the writings of both Comte and Spencer, there proceeded during the 19th century, under the influence of the evolutionary concept, a thoroughgoing transformation of older studies like History, Law and Political Economy; and the creation of new ones like Anthropology, Social Psychology, Comparative Religion, Criminology, Social Geography. It is from these sources that have sprung the main body of writing, investigation, research, that to-day can properly be called sociological. To give content to this statement some illustrative cases may be examined. Take, to begin with, the transformation of Law and History from relatively isolated studies of discursive or narrative type into something ever approximating to social sciences of an evolutionary kind. Discoveries relating to the history of the family contributed largely to the renewal of juristic studies on an evolutionary basis. Disputable as the theories of Bachhofen, Morgan, MacLennan, etc., were in many respects, they proved by evidence the existence of forms of the "family," very different from those known up to that time, and also their *generality*. The remarkable identity of the nomenclature of parentage in Australia, and among the redskins of North America, was significant. The similarities between the Iroquois tribes and the Romance nations, if exaggerated by Morgan, were not purely fictitious. Resemblances of the same kind were proved in the case of criminal law and the law of property, and thus a school of comparative law was founded, whose object was to bring out these agreements, to classify them systematically, and endeavour to explain them as evolutionary phenomena. Of this school of ethnographic jurisprudence Herman Post may be regarded as founder, and other names such as those of Kohler, Bernhoeft, and Steinmetz are to be associated with his.

Simultaneously with the foregoing changes, the concept of Institutions as social phenomena exerted a profound influence upon modes of study in both History and Law. It was observed that Institutions during their evolution preserve their essential characteristics throughout long periods of time, and even on occasion through all the series of a continuous collective existence; for they express the more constitutional elements in every social organization. Stripped of the covering of particular facts which conceals their internal structure and function, institutions, it could be asserted, while varying more or less from one country to another, presented striking similarities in different societies. *Rapprochements* thus became possible, and comparative history came into prominence. The Germanists and the German Romanists, Maurer, Wilda and Ihering, established resemblances between the laws of the various Germanic peoples, and between those of the Germans and Romans. By comparison of the classical texts relating to the organization of Greek and Roman cities, Fustel de Coulanges managed to portray in its essential particulars the abstract type of the city. With Sumner Maine, the field of comparison, still further widened, embracing besides Greece and Italy, India, Ireland, the Slav nations.

Political Economy.—Nothing better testifies to the importance of the scientific transformations in the whole field of social studies than the evolution which political economy underwent during the 19th century. Under the influence of different ideas, otherwise ill-defined, but which it is, however, possible to refer to two principal types, it lost, first in Germany something of that merely dialectical character which made it possible for Comte to contrast it with sociology as the type of the "idealogic" method of construction. To establish the legitimacy of Protection, and more generally of the economic action of the State, List reacted against both the individualism and the cosmopolitanism of the Liberal school. The "National System of Political Economy" maintains the principle that intermediate between humanity and the individual is the nation, with its language, literature, institutions, manners and past. The classical economist fashioned an economic world having no visible existence—the *Güterwelt*—an isolated world uniform throughout—in which the conflict of individual forces acted according to inflexible economic laws. As a matter of fact, it is observable that individuals make their efforts to grow rich in collectivities widely different from one another; and the nature of these efforts changes, and their success varies with the characteristics of the collectivity in which they are displayed. A practical consequence of this principle is that the State acts on the economic conduct of individuals by means of the "reforms" which it introduces, and by its external policy. A theoretical consequence is that economic "laws" are seen to vary from one nation to another, and it becomes increasingly manifest that a "National Economy" based on observation, should take the place of the abstract, *a priori* economics. True, the conception of a "nation" is an obscure idea; and the very definition of national economy would appear to negate the possibility of truly scientific laws, since it conceives its object as unique and excludes comparison. List made, nevertheless, an important step in advance by introducing into economic speculation the idea that a given society has a real existence, and that the economic and other manifestations of its own life are in reciprocal relations.

Under the title of "Socialism of the Chair," studies emerged, which, while attempting also to establish theoretically the political conception of the rule of the State, adapted and developed List's idea. It is not enough to say that economic activity of individuals is dependent on social phenomena; for is it not true that only by abstraction can we speak of individual economic activity? A more concrete reality is the *Volkswirtschaft,* the economic activity of society associated not only with economic, but also with ethical and juridical phenomena. This *Volkswirtschaft* was taken as the immediate object of economic science; it occupied itself essentially with social concerns, and, indirectly only, with individual interests. Here, political economy, though preserving a normative more than speculative character, was at least clearly conceived as a social science with truly social phenomena for its object, of the same nature as other social institutions.

Another phase of progress, akin to the foregoing, was accomplished at the same time. The historical spirit is applicable to all the particular characteristics which distinguish societies and epochs from one another. "National Economy" had therefore to find in

history its argument against the universalist theories of the classical school. List invokes the historical method; and Roscher, the founder of the historical school, does not separate the study of economic facts from that of juridical facts in particular, and from social facts in general. Language, religion, art, science, law, the state, and industry—all are viewed as different aspects of one complete whole, conceived as national life. This school has had a special influence in the development of political economy. Without at any time losing sight of historical research as a means of judging the value of a given political action in given circumstances, it has occupied itself with matters more or less apart from their practical aspect, and has insisted on studying them with a view to their understanding in a detached spirit. It has introduced to some slight extent the comparative method in economic history, and, among its most notable exponents, Schmoller clearly formulated the idea that economic laws are inductive. Another—Bucher—sketched a classification of economic régimes, thus constructing abstract types to which by their economic organisations all nations, whether present or past, might be assumed to belong. Both, and particularly the latter, were no longer content with studying historic societies. In particular they demanded information from ethnography as to the economic condition of lower races.

SPECIALIZED STUDIES

What, however, even more than this reconstruction of law, history and economics on a more or less evolutionary basis, constitutes the main movement towards a system of social sciences, is the appearance of a whole array of new disciplines of an essentially sociological nature. First, may be mentioned the two allied studies—Anthropology, and the Development of Civilization, which the Germans call *Kulturgeschichte;* and amongst the initiators may be mentioned Klemm in Germany, Pritchard in England, and Broca in France. The founding of prehistoric archaeology, by submitting evidence that the human race in very ancient times had everywhere passed through a state similar to that in which savage or barbarian peoples remain who can actually be observed to-day, went yet further in extending the field of these investigations and fortifying their methods. Not only the unity of human minds, but the relative identity of human evolution, was thus affirmed. The impulse once given, anthropologic discoveries rapidly followed one another, calling attention to remarkable similarities between the most different nations. This it was which the partial encyclopaedias of Schoolcraft and Bancroft revealed, but it was most clearly put in evidence by the great work of Waitz Gerland, in which is found synthesized the anthropological work of a whole epoch.

Comparative Religion.—Studies of religions have been submitted to an evolutionary treatment, which, however, has been applied, as yet, almost exclusively to the simple and more primitive forms of cult. With the help of comparative grammar, Max Müller founded comparative mythology; but this comparative study remained for a long while confined to the primitive historical religions of the Aryan nations. Under the influence of anthropology the field of comparison was widened. Numerous scholars, —Mannhardt in Germany, Tylor, Lang, Robertson Smith, Frazer, Sidney Hartland in England, Wilken in Holland,—collected a great number of facts which tended to prove the uniformity of religious beliefs and observances throughout the whole human race. Armed with the "survival" theory, the same authors annexed at one stroke to the comparative science of religions, the whole mass of facts which the Folklore or *Volkskunde* of the Germans—observed, registered and brought together during the 19th century—contained; and they received by that incorporation a new significance. The customs of European peasants, magical practices, ideas concerning death, tales and legends, all appeared now as the debris of ancient civilisation and ancient beliefs.

The Psychological Approach.—And a new science took its birth in Germany, with a view to studying the products of psychological activity in primitive minds or in the underlying mentalities of the more cultured peoples; that is, the *Völkerpsychologie* or folk-psychology, of which Lazarus and Steinthal are the founders. This has been but one of many psychological approaches towards an ever-growing enrichment of the sociological repertoire. The others most notable are: (a) observational and systematic studies of the child-mind in its growth from infancy onwards, culminating in the profound mental and emotional changes of adolescence. This approach has been pioneered mainly by Americans, and notably by Stanley Hall, whose great work *Adolescence* constitutes a landmark in the understanding of those mental changes which transform the "individual" into a social being; (b) the comparative study of animal and human societies, pioneered by Darwin's investigations of emotional expression in animal life; developed by Espinasse in his *Les Sociétés Animales;* and carried fully into the world of man by Trotter in his *Instincts of the Herd in Peace and War;* (c) Durkheim's theory of *Collective Representations,* which goes to show that men united in organised groups think and feel differently from isolated individuals; that societies have *representations* which are peculiar to them, collective representations charged with collective emotions; and that these representations (beliefs, myths, aesthetic images, moral notions, scientific concepts, technical ideas), form the greater part of thought and sensibility strictly human; that it is by its participation in this collective treasure that the thought of individuals surpasses that of animals; and finally above all that these collective representations express not only the exterior world and the individual consciousness, but society itself, a real being and a system of forces, which dominate individuals and act in and through them; (d) the psycho-analytic school founded by Freud and Breuer (but developed by the former and his pupils and continuators, notably Jung and Adler), which shows, with a wealth of detail, how the mind of every individual is built up by a complex interplay between more or less organic impulses (especially those of sex) and social factors such as parental control, the inhibitions and ordinances of custom, the aspirations and repressions of manners, law, religion, politics, etc.

Partial Sociologies.—From the foregoing psychological approaches collectively there is growing up a doctrine of society, its structure, functions, origins and purpose which, in popular estimation, probably outranges any sociological presentation as yet made. Similarly the anthropologists are in course of creating a sociology of their own. Ignoring the vast and profound labours of Comte in establishing and elaborating the concept of Social Inheritance as the differential characteristic of Man in society and therefore the essential subject matter of sociology, those anthropologists who emphasize and work out the idea of Cultural Diffusion are in danger of substituting a biassed particularism for the synthetic generality which a genuine sociology demands. And the same criticism could be levelled against the more generalizing exponents in each one of many specialized subsciences found within the social field. Since these specialisms began, under the influence of the evolutionary spirit, to orient themselves in a sociological direction (as illustrated above), they have collectively accumulated a body of more or less verified knowledge, which to-day must be held to constitute the main corpus of sociology, if that word be taken in a scientific rather than a philosophic sense. But this body of specialized knowledge suffers several grave defects. It is, (a) unsystematized, and therefore, since lacking in real unity, is ill-adapted to the concerted activity on which assured progress in science depends; (b) uninformed by many of the master concepts on which the scientific foundations of sociology were originally laid; (c) inadequately related to biology and the other established sciences which, preliminary to sociology, compose an essential part of the equipment needed for the culminating study of society in evolution. Meantime an expanding flood of literature, in book and periodical form, appearing under the title Sociology gives too much occasion for a widely prevailing belief that sociology is a vague general study of discursive and philosophical rather than scientific character.

LE PLAY AND HIS CONTINUATORS

Two of the grand sources of current sociology have been indicated, viz., on the one hand, the initiative work of Comte and his continuator Spencer, and on the other, the multifarious and unco-ordinated researches of numerous specialized studies which

are, or should be, subsciences of one comprehensive master science. There is a third grand source. It is the writings, impulse and tradition of Frédéric Le Play (1806–1882). He is to be regarded as the creator of an observational method, applicable to concrete outdoor studies in the social sciences, which holds promise of freeing sociology from its dialectical and discursive bias, bringing it into line with biology, and so imparting to it a definite and recognized place in the hierarchy of the sciences. Le Play is best known in England and America for his monumental work *Les Oeuvriers Européens.* In preparation for this, Le Play spent in foreign travel and observation, during more than a score of years, the annual holiday of five to six months which his official duties (as Inspector of Mines) allowed. He visited nearly every country in Europe (England seven times), and extended his travels into Asia. He thus studied and monographed over three hundred working-class families representative of characteristic industries and localities throughout Europe. From all these "Monographies Sociales," thirty-six of the most complete were selected for publication in the *Oeuvriers Européens,* the first edition of which appeared in 1855. Le Play's system of monographs inspired the classic work of Charles Booth in his *Life and Labour of the People in London* (10 vols. 1889–1903, now under systematic revision by the London School of Economics). From the same source came the model and inspiration of much investigation and research in Britain and America on Family Budgets. In these ways Le Play's influence has been conspicuous in helping to transform the older type of discursive political economy into an observational and concrete study growing increasingly fit to take its place as a specialized subscience of a renovated sociology.

The Elemental Occupations.—The social monographs of Le Play which have exerted a marked influence in re-orienting Political Economy in a sociological direction, were themselves antecedent to his later and more mature work upon the primary occupations. In the elemental activities of Hunting, Herding, Mining, Woodcraft, Agriculture and Fishing, which primitively and perennially link Man with Nature, Le Play and his continuators (notably De Tourville and Demolins in France, and Patrick Geddes in Britain), discovered material for the renovating of sociology (though Le Play himself never used that word) extending far beyond the purview of anthropology, economics and social geography. Le Play's original formula of Lieu, Travail, Famille, used in the study of these nature occupations, has grown into the Place, Work, Folk, of a school at once observational and interpretative, which pushes on from "field" studies of the simpler peoples into the most elaborate urban and rural phenomena of civilization.

But, to study these nature-occupations on the spot, most students will not need to go further afield than to the more mountainous regions of their own country, such as the moorlands, glens, forests and estuaries of the Welsh, Scottish and Irish Highlands, or even to the English Pennines. In the course of a walking tour down a typical valley of these regions one can usually see something both of the nature-occupations and of their mode of family and folk life, and how these are conditioned by environment. Picture for instance the appearance of a typical valley as seen, for example, from an aeroplane. On the broad hill-tops, bare rock or moss-grown surface alternating with scrub, heath and bracken, the whole affording scanty food and cover for game, of which the grand source is in the deciduous forest below, sheltering a rich variety of animal life; next is the belt of upland pasture with its wandering flocks; below this the agricultural belt ranging from the poor hill-side croft onwards through the rich farms of the plains, to the market gardens on the outskirts of the great city at the river mouth. Finally, at the estuary is the region of the seafaring folk. Here are four characteristic areas, and the addition of the coniferous forest and mining belts on the western slope altogether make up, as it were, a six-square chequer board. On their respective squares stand the sextet of occupational types, Miner, Woodman, Hunter, Shepherd, Peasant, Fisherman, each ready for his part in the interplay of the rural drama, which constitutes the subject matter of the rural survey.

Pursued systematically, such an investigation is a Rural Survey of genuinely scientific type. If the student pauses to specialize on its environmental aspects, the study becomes social geography; if on aspects of work, it becomes economics; if on folk life and custom, anthropology. Thus these three large sub-sciences of the social group fall into orderly relation to each other and to the facts under investigation. Attempts to co-ordinate these more determinist or objective sciences (social geography, economics and anthropology) give rise to sociology in its more determinist and objective sense.

The Civic Survey.—Now the typical river valley that constitutes the unit of open-air survey, pursued in the Le Play tradition, has, of course, its towns or cities at "nodal" points, and often its great city at the river mouth. In the survey of these towns and cities, the central interest is not nature-occupations, but culture occupations, commonly called vocations. On the more social side, it is not family and folk custom that we emphasize, but the group of people associated for some immaterial purpose (as of religion, political progress, science, literature, art, etc.). Such a group becomes an institution, when lastingly organized. And the word "Polity" may conveniently denote all such groups alike the more and the less permanently organized. In the higher forms of city life, polities largely determine vocation; young men (and, increasingly, young women) choosing careers in relation to the polities with which they are associated. Vocation freely chosen usually results in a development of personality which produces some form of art, and thereby transforms "place" (environment) in terms of purpose. Thus the Civic Survey supplements the Rural Survey and in the former the terms and sequence of the formula used for observation and for interpretation are—Polity →Culture→Art. And this, manifestly, is the formula of the rustic survey reversed, and read as Folk→Work→Place, but with more appropriate civic terms replacing those of the rustic formula. Pausing in the civic survey to specialize on polities, we are from one point of view studying Ethics, and from another (speculative) Polities; specializing on cultures (as embodied in militant types of personality), we study from one point of view History (as Biography) from another, Social Psychology (the "Ethology" of J. S. Mill); specializing on studies of environment transformed to art, our sub-science is Aesthetics. Thus do the more subjective or "idealistic" social sciences take orderly rank in the scheme.

Sociology in its more subjective aspect emerges as the endeavour to co-ordinate these. Rustic surveys combine with civic surveys to make the Regional Survey (*i.e.,* systematic study of the various human societies inhabiting a given region). And as such surveys proceed city by city, region by region, their comparison and generalization should yield a unified social science with adequate and orderly basis of fact. Amongst the advantages claimed for this method are: (1) it supersedes the old-standing dispute between the "sciences" and the "humanities" by bringing them together as the more objective and subjective approaches to the one single study of social life in evolution; (2) it continues the concrete open air method of Nature Study into the human field, thus finding its material in the objects of everyday observation, and putting the student face to face with these, and only falling back on books and classroom work as a secondary aid; (3) it parallelizes the social with the biological sciences, not through the old vague "organic analogy," but by precise correspondence of the elemental concepts in each order of science. Place, work, folk, are manifestly the social equivalents of the biologist's elemental triad, environment, function, organism. The biologist, as his observations ascend the scale of life, sees organisms decreasingly hammered into shape by environment, and increasingly modifying environment in terms of their own vital activities. So also the social student reverses his determinist formula in passing from rustic to civic surveys, and adapts its terms to the observation and interpretation of life, individual and social, increasingly impelled towards the expression and realization of ideals.

THE FUTURE OF SOCIOLOGY

Unfortunately, there does not, as yet, exist any monographic study of the typical Region—a river valley, which, from source

to sea, can be taken as representative of a given civilization. Indeed an organization adapted to a working correlation of all the relevant specialisms, both social and naturalist, has still to be created for this purpose. But there are small tentative beginnings such as the Outlook Tower in Edinburgh, and Le Play House in London. To be sure, many "surveys" of particular cities, towns, villages and other areas, have been, and continue to be, made and published, especially in America. But these are social rather than sociological. In other words such usage, systematization and even synthesis of specialisms, as they make and apply to observation and interpretation of their region, are either personal or appertain to some sectional tradition rather than to the main line of sociological advance. It may well be that effective progress towards the establishment and maintenance of sociology as the culminating synthetic member in the hierarchy of the sciences awaits the coming of a generation of students and investigators, observers and interpreters all of whom shall have been specially trained in definite ways.

These, without doubt, must include: (a) a working knowledge of Comte's master-generalization still awaiting thoroughgoing application to recent history and contemporary social evolution as well as to past history, *i.e.*, of congruent temporal and spiritual powers, operating through characteristic social types for which he used as technical terms, "chiefs" and "people" for the respective arms of the temporal power; and similarly "intellectuals" and "emotionals" for those of the spiritual power; (b) a similar habit of using for everyday observation and interpretation, both versions of Le Play's reversible formula (Place, Work, Folk); (c) a working knowledge of Geddes' development and elaboration of the Le Play formula; (d) a preliminary training in biology and in field-naturalist modes of observation and study; (e) some mastery of contemporary resources in (social) geography, economics and anthropology as the three chief subsciences of sociology on its objective side, and similarly for ethics, psychology and aesthetics as the three chief subsciences of sociology on its subjective side; (f) recurrent travel on foot particularly for observation of the elemental occupations with their rural varieties and their transformations in urban life; (g) similar open-air studies of historic formations and their survivals and renewals in town and country; (h) habitual watching (and interpreting) everywhere and at all times of the interplay between past, present and future; (i) unflagging endeavours to discern the "individuality" of every village, town and city, as a unique factor in the "culture" which every region receives and reflects from the larger civilization; (j) a clear distinction between organic heredity and social inheritance; and persistent effort to see and evaluate the social heritage not only in language and literature, art and religion, occupations, manners, customs, business and politics, but also and more concretely in the edifices, streets and quarters of towns and cities; and above all in the complex life of a whole region fully representative of a given civilization.

Equipped with these (and no doubt other) essentials of his science, the coming sociologist will work towards the long-delayed synthesis of the newer specialisms and of these specialisms with the older studies and knowledges.

BIBLIOGRAPHY.—The great bulk of sociological literature is either specialized on some one or more of the many approaches (economic, anthropologic, psychological, juristic, etc.), or proceeds by a method more dialectical and discursive than observational and hence belongs rather to social philosophy than to science. The best of both kinds will be found either in the specialized journals or in the general reviews. Of the latter the chief are *The Sociological Review* (the organ of the British Sociological Society); *The American Journal of Sociology; Social Forces; The Journal of Applied Sociology* (both the latter, American); the *Année Sociologique* (which summarizes the chief books of the year); the *Revue Internationale de Sociologie;* the *Archiv für Sozialwissenschaft und Sozial politik; Kölner Vierteljahrschrift für Soziologie; Jahrbuch für Soziologie; Ethos: Vierteljahrschrift für Soziologie, Geschichte und Kultur-philosophie; Zeitschrift für Völkerpsychologie und Soziologie;* and the *Rivista di Sociologia.* For the titles of specialized periodicals *see* the relevant articles (Economics, Anthropology, etc.). Of general works may be mentioned: J. J. Findlay, *An Introduction to Sociology* (1920); R. M. MacIver, *Elements of Social Science* (1926); and four books by L. T. Hobhouse, together constituting his principles of sociology, viz., *The Metaphysical Theory of the State* (1926), *The Rational Good* (1921), *The Elements of Social Justice* (1922), *Social Development* (1924); Ellwood's *Cultural Evolution* (1927); Park and Burgess, *Introduction to the Science of Sociology* (1921); Graham Wallas, *The Great Society* (1919); E. R. Groves, *An Introduction to Sociology* (1928), and *Sociological Papers* (British Sociological Society, 1904–06) attempted a comprehensive systematization. On the general history of sociology, *see* E. Bogardus, *History of Social Thought* (Los Angeles, 1922); S. O. Hertzler, *History of Utopian Thought* (1923); J. P. Lichtenberg, *Development of Social Theory* (1924); Albion W. Small, *Origins of Sociology* (1924). For social psychology, *see* L. L. Bernard, *An Introduction to Social Psychology* (1927); C. A. Ellwood, *Psychology of Human Society* (1925); M. Ginsberg, *The Psychology of Society* (1924); W. McDougall, *The Group Mind* (2nd ed., 1927). For the development of the regional survey and its applications, *see* various papers by P. Geddes contributed to the (British) Sociological Society from 1904 onwards, and in two books written jointly with V. Branford, *The Coming Polity* (2nd ed., 1919) and *Our Social Inheritance* (1919); and in *Whitherwards,* by V. Branford. A small *Introduction to Regional Surveys* by S. Branford and A. Farquharson is useful for field work. For an account of the recent and current state of sociological studies in France, Germany and America, *see* three papers respectively by P. Fauconnet, L. von Wiese, and C. A. Ellwood, in the *Sociological Review* for January 1927. As regards social service, *see* "A Select Bibliography," in W. J. Roland's *Social Service,* and *see* also the article SOCIAL SERVICE. (V. BR.)

SOCRATES (*c.* 470 B.C.–399 B.C.), the great Athenian philosopher, was put to death in 399 B.C. at the age of 70. His birth thus falls in or about 470, ten years after Salamis. His father, Sophroniscus, was a friend of the family of the "Just" Aristeides; the tale that he was a sculptor first appears in the 3rd century in Timon of Phlius and seems to be only a misinterpretation of a playful remark in Plato. His mother, Phaenarete, acted as a "midwife," but no inference as to social status can be founded on this. The memoir writer, Ion of Chios, mentioned meeting him at Samos in the company of Archelaus, the Athenian successor of Anaxagoras, presumably during the military operations of 441–440. The connection between the two men is also asserted by Aristoxenus the Peripatetic and the doxographical tradition based on Theophrastus calls Socrates the "disciple" of Archelaus. Plato, Xenophon, Aeschines of Sphettus agree in depicting him as intimate with the leading figures of the Periclean circle (Aspasia, Alcibiades, Axiochus, Callias). Xenophon (*Mem.* iv. 7) concurs with Plato in saying that he was well versed in geometry and astronomy, and this representation agrees with the narrative of Plato's *Phaedo* and the Aristophanic burlesque of the *Clouds.* Socrates must already have been a conspicuous figure at Athens when Aristophanes and Ameipsias both made him the subject of their comedies in 423, and since the comedians made a special point of his neediness he had probably suffered recent losses. (The marked poverty of his old age is said in Plato's *Apology* to have been caused by his preoccupation with his mission to mankind.) Socrates was married, apparently late in life, to Xanthippe, by whom he left three sons, one an infant. Xenophon speaks of her high temper; there is no evidence that she was a "shrew"; the sons, according to Aristotle, proved insignificant (*Rhetoric B.,* 1390, b. 31).

Socrates' record for prowess and endurance was distinguished. He served as a hoplite, perhaps at Samos (441–440), at Potidaea, where he saved the life of Alcibiades (432–430), Delium (424) and Amphipolis (?422 or ?437–436). In politics he took no part, knowing, as he told his judges, that office would mean compromise with his principles. Once at least,[1] in 406–5 he was a member of the council of 500, and at the trial of the victors of Arginusae, being one of the *prutaneis,* resisted, at first with the support of his colleagues, afterwards alone, the unconstitutional condemnation of the generals by a collective verdict. He showed the same courage two years later in the "Terror" of 404. The "thirty" wishing to implicate honourable men in their proceedings, instructed Socrates with four others to arrest Leon, one of their victims. Socrates disobeyed, and says, in Plato's *Apology,* that this might have cost him his life but for the counter-revolution of the next year.

In 399, four years after the amnesty, he was indicted for "impiety." The author of the proceeding was the influential Anytus, one of the two chiefs of the restored democrats, but the

[1]This was not, of course, a "magistracy." Plato, *Gorgias* 474*a,* seems to refer to another earlier occasion.

nominal prosecutor was the obscure and insignificant Meletus. There were two counts in the accusation, "corruption of the young" and "neglect of the gods when the city worships and the practice of religious novelties."[1] Socrates, who treated the charge with contempt and made a "defence" which amounts to avowal and justification, was convicted, probably by 280 votes against 220. The prosecutors had asked for the penalty of death; it now rested with the accused to make a counter-proposition. A smaller, but substantial, penalty would have been accepted, but Socrates took the high line that he really merited the treatment of an eminent benefactor, maintenance at the public table. He only consented for form's sake to suggest the small fine of one *mina*, raised at the entreaty of his friends to 30.

This incensed the court and "death" was voted by an increased majority,[2] a result with which Socrates declared himself well content. As a rule at Athens the condemned man "drank the hemlock" within 24 hours, but in the case of Socrates the fact that no execution could take place during the absence of the sacred ship sent yearly to Delos caused an unexpected delay of a month, during which Socrates remained in prison, receiving his friends and conversing with them in his usual manner daily. An escape was planned by his friend Crito, but Socrates refused to hear of it, on the ground that the verdict, though contrary to fact, was that of a legitimate court, and must therefore be obeyed. The story of his last day has been perfectly told in the *Phaedo* of Plato, who, though not himself an eye-witness, was in close touch with many of those who were present.

Socrates wrote nothing; therefore our information about his personality and doctrine has to be sought chiefly in the dialogues of Plato and the *Memorabilia* of Xenophon. Both men were nearly 45 years younger than Socrates, and can therefore only speak from first-hand knowledge about the last ten or twelve years of his life. Xenophon's relations with him seem not to have been close, and he has even been suspected of deriving much of his material from Plato's dialogues. His admitted deficiencies in imagination and capacity for thinking do not make him the more faithful exponent of a philosophical genius.

To call him a "Boswell" does poor justice to the intellect of Boswell. (It must also be remembered that Boswell collected his material largely during Johnson's life, and with his knowledge and help.) We need also to discount Xenophon's apologetic purpose. His most valuable statements are those which appear most at variance with his main thesis that the prosecutors of Socrates were mistaken from their own point of view. Plato's more vivid picture has been suspected on the ground that Plato used Socrates as a "mouthpiece" for speculations of his own. What this really means is that the so-called "Ideal Theory" expounded in the *Phaedo* is held to have been originated by Plato after the death of Socrates. There are serious reasons for denying this assumption though they have not yet convinced all scholars; in any case it is a *petitio principii* to employ it, without investigation, as an argument to discredit Plato's testimony. Xenophon's silence at most only proves that Socrates did not converse on such matters with him. In some important respects Plato's testimony is confirmed by the remains of Aeschines of Sphettus. The *Clouds* of Aristophanes yields valuable information about Socrates in his middle "forties," when allowance is made for its character as a burlesque. It should be compared carefully with the autobiographical statements put into the mouth of Socrates in the *Phaedo* (96*a*–100*a*). These are not "contemporary evidence," but they are clearly meant to express Plato's *bona fide* belief about his master's intellectual history.

Personal Characteristics.—Though Socrates was a good fighting man, his outward appearance was grotesque. Stout and not tall, with prominent eyes, snub nose, broad nostrils and wide mouth, he seemed a very Silenus. But, as his friends knew, he was "all glorious within," "the most righteous man of the whole age" (Plato, *Ep.* vii. 326 *e*). His self-control and powers of endurance were exemplary; "he had so schooled himself to moderation that his scanty means satisfied all his wants."

But he was no self-tormenting ascetic; he "knew both how to want and how to abound," and could be the soul of the merriment at a gay party. He had no sympathy—this was a main point in the *Telauges* of Aeschines—with the slatternliness of his friend Antisthenes or the godly dirtiness affected by "Pythagorists." There was nothing of the complacent self-righteousness of the Pharisee, nor of the angry bitterness of the satirist, in his attitude towards the follies or even the crimes of his fellow men. It was his deep and life-long conviction that the improvement not only of himself, but of those with whom he might have to do, was a task laid upon him "by God," but the task was not to be executed with a scowling face and an upbraiding voice. Like St. Francis Xavier, he thoroughly understood how important it is to one who would win men's souls to be "good company." Conscious of his own infirmities, he felt a real and profound sympathy for those who had not learned to master their frailties and passions.

He was a true patriot, and his devotion to the city in which he had been born and bred was only made the more evident by his conviction that he could best prove it by setting his face resolutely against the attractions of specious and popular, but deadly, false theories of public and private morality. When the city brought him to trial and threatened him with death his sense of civic duty forbade him to withdraw into exile before the trial, or to accept the opportunity of escape during his unforeseen imprisonment. It was his very patriotism which made him an unsparing critic of the "democracy," which means, in Nietzsche's phrase, "one flock and no shepherd," and so led directly to the accusation which proved fatal to him.

Nothing was more marked in his character than an unusually keen sense of humour, an appreciation of the comic in human nature and conduct which protected him at once against sentimentality and against cynicism. This is what his opponents in Plato call his "irony," and treat as an irritating affectation. "Intellectually the acutest man of his age, he represents himself in all companies as the dullest person present. Morally the purest, he affects to be the slave of passion" (W. H. Thompson). No doubt, in part this irony was "calculated"; it "disarmed ridicule by anticipating it." But its true source is the spontaneous sense of "fun" which makes its possessor the enemy of all pretentiousness, moral or intellectual, in himself and in others. And it is certain that, though the purity of Socrates is beyond question, he really had an ardent and amorous temperament.[3]

Religion.—Socrates was clearly a man of deep piety with the temperament of a "mystic." Like other educated men of his age, he regarded mythology, with its foolish or immoral tales about gods, as a mere invention of the poets. But he found it easy to combine his own strong belief in God, the all-wise and all-good ruler of the world, with the view that in practice we could worship God in the way prescribed by "the usage of the city." God's existence is shown, he held, not only by the providential order of nature and the universality of the belief in Him, but by warnings and revelations given in dreams, signs, oracles. The soul of man partakes of the Divine; the concluding pages of Plato's *Apology* prove that Socrates had a strong belief in its immortality. (Xenophon for apologetic reasons is silent on the point, but has reproduced the argument in the dying speech of his Cyrus in the *Cyropaedia*. Aristophanes, too, makes Socrates combine the parts of "infidel" physicist and hierophant of a mysterious private faith, and in the *Birds* [1553, *seq.*] represents him as presiding at a fraudulent *séance*.) He was regular, says Xenophon, in prayer and sacrifice, though he held that since only the gods know what is good for us, our prayer should simply be "give me what is good"; we must not dictate the form the blessing should take. It is clear from Plato that Socrates was deeply influenced by Pythagorean and Orphic religious ideas, though he regarded the ordinary Orphic mystery-monger with healthy contempt.

[1] *καινὰ δαιμόνια* in the edictment means literally "novel practices in religion," not "novel deities," (though the second is insinuated).

[2] What offended the court was not the smallness of this sum—30 *minae* was not a small sum in the economic circumstances of the time—but Socrates' description of himself as a distinguished public benefactor.

[3] *Cf.* Aeschines, *Alcibiades* Fr. 4 (Krauss), which confirms the representation of Plato on this point.

The evidence that Socrates had a markedly "mystical" temperament is abundant. Plato tells of his curious "rapts," in one of which he stood spellbound for 24 hours in the trenches before Potidaea, and there seems to be an allusion to this singularity in the *Clouds* (171 *seq.*).

The familiar "Divine sign" tells the same story. This, according to Plato, was a "voice" often heard by Socrates from childhood. It forbade him to do things; but never gave positive encouragement. (Xenophon, who makes more of the matter, says, less probably, that it did give positive directions.) Plato treats the "voice" very lightly; by his account, it merely gave prognostications of good or ill luck, and the occasions of its occurrence were often "very trivial." Thus it was neither an "intuitive conscience," nor a symptom of mental disorder, but an "interior audition," a "psychic phenomenon" of a kind now known to be not specially uncommon.

Mode of Life.—Socrates' whole time seemed to be spent "out of doors," in the streets, the market-place, and more particularly, the *gymnasia.* He cared little for the country and rarely passed the gates. Though he frequented by choice the society of lads of promise, he also talked freely to politicians, poets, artisans about their various callings, their notions of right and wrong, the familiar matters in which they might be expected to take an interest. The object of all this, he says in the *Apology,* was to test the famous Delphic oracle which had pronounced him the wisest of men. It is clear from the *Apology* that the oracle had made this declaration, no doubt because the Delphic authorities knew from the form of the question what answer was desired. The presupposition of the *Apology* is that this happened before Socrates had become conscious of his mission to his fellow men; even at that early date, it is implied, he had the highest of reputations in circles interested in wisdom.[1] Acutely sensible of his own ignorance, Socrates set himself to convict "the god" of falsehood.

But when experience showed that those who thought themselves wise were unable to give any coherent account of their wisdom, he had to admit that he was wiser than others, just because he alone was aware of his own ignorance. This account is plainly tinged with the usual "irony." Socrates did not take Apollo and his oracle very seriously. But that he was quite serious in believing himself charged with a mission, not from "Apollo," but from God, to preach to his fellow men the supreme importance of knowledge of what is for the soul's good is proved by his declaration that he is more than ready to face instant death rather than to neglect his commission. The poverty in which this mission had involved him, and the austerity of the rule of life it entailed were notorious.

Summer and winter, his coat was the same; he had neither shoes nor shirt. "A slave who was made to live so," the sophist Antiphon said, "would run away." This self-imposed life of hardships was the price of his spiritual independence. His message was variously received. Some of those whose false pretentions were exposed by his trenchant criticizing regarded him with ill-will; many thought him an officious busybody. Among the younger men, many merely thought it good sport to see their elders silenced. Others (Xenophon says that this was the case with Alcibiades and Critias), deliberately attached themselves to him for a time "for private ends," believing that to learn the secret of so acute a reasoner would be the best preparation for success in the law courts, the council and the assembly. Others sincerely hoped by associating with him to become good men and true, capable of doing their duty by house and household, by relations and friends, by city and fellow-citizens.

Finally, there was an inner circle who entered more deeply into his principles and transmitted them to the next generation. But these were not "disciples" united by a common doctrine. Socrates finally repudiated all claim to have "disciples." The bond of union was a common reverence for a great man's intellect and character. It was, in the main, this group who were collected round Socrates in the day of his death; many of them, *e.g.,* Eucleides from Megara, and the young Theban Pythagoreans, Cebes and Simmias, were foreigners from States which had been enemies of Athens in the Peloponnesian War.

[1]This is also proved by the attachment to him shown by Eleatics from Megara and young pupils of the Pythagoreans from Thebes and Philius. These connections must have been founded before the Peloponnesian War

The Accusation and Its Causes.—The explanation of the attack made on Socrates is simple. He had been on terms of close friendship with the two men whose memories were most obnoxious to the democrats, Critias, the fiercest spirit among the extremists of the "Terror" of 404, and Alcibiades, whose self-will had done so much to bring about the downfall of the Athenian empire. The charge of "educating Alcibiades" was made prominent in the pamphlet written a few years after the trial by the "sophist," Polycrates, in justification of the verdict. More than half a century later, the orator Aeschines reminds his audience that Socrates had been put to death because he was believed to have educated Critias. In point of fact, it was absurd to make Socrates responsible for the ambitions of Alcibiades, and, as he reminded his judges, he had disobeyed an illegal order from Critias and his colleagues at the risk of his life. But it is natural that he should have had to suffer for the crimes of both men, the more that he was known to have been an unsparing critic of democracy, and of the famous democratic leaders. These suspicions would be made the more acute by the remembrance that Socrates had not, like the advanced democrats, withdrawn from Athens during the "Terror."

He was, in fact, suspected of using great abilities and gifts to pervert his younger associates from loyalty to the principles of democracy, and the convinced democrats who had recovered the city in 403 were unwilling, as Burnet has said, "to leave their work at the mercy of reaction." That they took no steps for four years is probably explained by the state of complete confusion and congestion into which the disorders of 404 had thrown the law courts. The motives of Anytus, an upright, unintelligent democrat, are thus quite explicable. From his point of view, Socrates would be at the best a "whig," and democrats who remembered the career of Theramenes could not be expected to make a fine distinction between the "whig" and the traitor.

The real grounds for the attack could not be disclosed in the indictment, since the amnesty which terminated the struggle of 404–403, and of which Anytus himself had been a main promoter, covered all offences committed before the archonship of Eucleides (403). Hence the charge had to be couched in the form of a vague accusation of "corruption of the young." Probably for the same reasons Anytus was ashamed to appear as the principal in the matter and put forward the obscure Meletus, who might venture on "indiscretions" more openly. If Meletus was the same person who also prosecuted Andocides in the same year on the same charge of "impiety," and if, as is not unlikely, he is the real author of the speech *Against Andocides* ascribed to Lysias, he must have been a half-witted fanatic, and this may explain why the charge of irreligion was added. The real nature of this "irreligion" appears never to have been explained. Xenophon suggests that the allusion was to the "Divine sign" but this cannot be correct. It is clear from Plato's *Apology* that Meletus said nothing about the "sign" at the prosecution, and that Socrates is speaking with his "usual irony" when he pretends to guess that the mention of "religious novelties" in the indictment referred to it. In the *Apology,* Socrates says that the prosecution is, no doubt, relying on memories of Aristophanes' *Clouds,* where he had been made to talk "atheism" as part of the burlesque on men of science.

But there must have been more behind the charge, and it seems likely that Burnet is right in reminding us that the prosecution of Andocides revived the old scandal of the "profanation of the mysteries," which had thrown Athens into a ferment on the eve of the Sicilian expedition in 416–415. The two chief victims, Alcibiades and his uncle Axiochus, were both among the intimates of Socrates, and there is reason to think that others of his friends were affected. If this is what lay behind the charge, we can understand why its real meaning seems never to have been explained. Owing to the terms of the amnesty, the matters in question were not really within the competency of the court. Socrates himself, in the account of Plato, who was present at the trial, treats the whole matter with contempt. His defence consists in narrating the facts

of his past life, which proved that he was equally ready to defy the populace and the "thirty" in the cause of right and law, and in insisting on the reality of his mission from God and his determination to discharge it, even at the cost of life. The prosecutors had no desire for blood. They counted on a voluntary withdrawal of the accused from the jurisdiction before trial; the death penalty was proposed to make such a withdrawal certain. Socrates himself forced the issue by refusing at any stage to do anything involving the least shade of compromise. The prosecution had raised the question whether he was a traitor or, as he held himself to be, an envoy from God; Socrates was determined that the judges should give a direct verdict on the issue without evasion. This is what makes him a martyr, but also what forbids us to call Anytus a murderer.

Doctrine and Method.—Socrates was a man of the Periclean age, and the Periclean age witnessed one of the periodical "bankruptcies of science." Cosmological speculation, which had been boldly pursued from the beginning of the 6th century seemed by the middle of the 5th to have led to a chaos of conflicting systems, each of which could establish only one point, that all its rivals were wrong. Parmenides of Elea had apparently cut away the ground from science by showing that the real world must be quite unlike anything which our senses reveal to us, and that, consequently, the method of cosmology, interpretation of the world by analogies from familiar sensible experiences, is inherently fallacious. His pupil Zeno seemed to have shown that even the postulates of mathematics are mutually contradictory.

Science, then, seems impossible, and this is why the ablest men of the generation before Socrates, such as Protagoras and Gorgias, turned away from the pursuit of it and tried to find a use for the intellect in professions which concern themselves, not with the discovery of truth, but with making a success of human life. "Probability is the very guide of life," and in practical matters "useful" points of view may be attainable, even if scientific certainty is beyond our reach. According to the narrative of the *Phaedo*, Socrates, as a young man, began with an experience typical of his age. He was enthusiastically interested in "natural science," and familiarized himself with the various current systems, being specially interested in the contrast between the old Milesian type of cosmology with its flat earth and the Italian type with its spherical earth. He was also interested in the mathematical puzzles raised by Zeno about "the unit" (*i.e.*, the problem of continuity). He discovered, to his distress, that though each authority was quite sure that the views of the others were wrong, none of them could give any proof that his own were right.

There was a complete lack of critical method. For a moment he hoped to find salvation in the doctrine of Anaxagoras that "mind" is the source of all cosmic order, since this seemed to mean that "everything is ordered as it is best that it should be," that the universe is a rational teleological system. But on reading the book of Anaxagoras, he found that the philosopher made no effective use of his principle; the details of his scheme were as arbitrary as those of any other. After this disappointment, Socrates decided that he had "no head for physics" and must fall back on his own mother-wit. Accordingly he resolved henceforth to consider primarily not "facts" but λόγοι the "statements" or "propositions" we make about them. His method should be to start with whatever seemed the most satisfactory "hypothesis," or postulate, about a given subject, and to consider the consequences which follow from it. So far as these consequences prove to be true and consistent, the "hypothesis" may be regarded as provisionally confirmed; if they are false or mutually inconsistent it is discredited. But it must be a strict rule of method not to confuse enquiry into the consequences of the "hypothesis" with proof of its truth. If the question of its truth is raised, the issue can only be settled by deducing the initial "hypothesis" as a consequence from some more ultimate "hypothesis" which both parties to the dispute are content to accept. The method, still familiar to us as that of true science, is manifestly suggested by reflection on the "antinomies" of Zeno, whom Aristotle called the creator of "dialectic," and whom Plato, in the *Parmenides*, afterwards described as meeting Socrates in the youth of the latter. So far, Plato's story has every appearance of being historical. But it is still the fashion to hesitate to follow it any further. According to him, Socrates next proceeded to take it as his own fundamental "hypothesis" that every term (such as "good," "beautiful," "man") which has a single unequivocal denotation directly names a single self-same object of a kind inaccessible to sense-perception and apprehensible only by thought. Such an object Socrates calls an ἰδέα or εἶδος, Form. (The transliteration "Idea" is misleading, owing to the psychologizing of the sense of the word by Locke and his followers.) The sensible things of which we predicate beauty, goodness, humanity, have only a secondary and derivative reality. Strictly speaking, we must not say that they *are* this or that, but only that they *become* this or that for a time, in virtue of the temporary "presence" (παρουσία) to them of the corresponding Form, or, as it is also expressed, in virtue of their "participation" (μέθεξις) in the Form. A sensible thing, in fact, is simply a temporary complex of Forms.

In the *Parmenides* of Plato Socrates is made to expound this doctrine to the great philosophers Parmenides and Zeno as his solution of the standing puzzle of the one and the many. This is the doctrine of Forms (the "Ideal Theory") as it is stated in the *Phaedo* and *Republic*. Though it is quite different from the version of the doctrine ascribed by Aristotle to Plato, it has been usual in the 19th century to assume that it is an earlier form of that doctrine consciously devised by Plato after the death of Socrates. The chief argument for this view is based upon the observation of Aristotle that Socrates rightly "did not separate" the universal from the particular (*Met. M.*, 1078 *b*30) as, it is apparently implied, Plato did. It is, however, not clear that Aristotle means by this, what he never says expressly, that Socrates did not teach the doctrine ascribed to him in the *Phaedo*. He might equally mean that the doctrine of the *Phaedo* does not itself involve the kind of "separation" of the universal from the particular to which he objects in what he describes as the Platonic theory, and, since the *Phaedo* is one of the Platonic dialogues to which he most frequently alludes, it is strange that he should never have said that it misrepresents the historical Socrates on a capital point, if he really thought so.

On the other side, the doctrine is expressly said in the *Phaedo* to be a familiar one which Socrates "was always" repeating, and it is hard to believe that Plato could have made such a statement about a speculation of his own, especially as most of the personages of the *Phaedo* were certainly still alive long after the dialogue was written. It is hard to see what could be the point of such a mystification, and harder to understand how its author could have expected it to be successful. Of course, demonstration is out of the question in such a matter; we can only be guided by considerations of probability. If we think the probabilities against the view which credits Plato with deliberate mystification, we must be prepared to admit the possibility that he is also reproducing the thought of Socrates in the further development of the *Symposium* and *Republic*, where we hear of a supreme Form, that of Beauty, or Good, the vision of which is the far-off goal of all intellectual contemplation. We may fairly suspect that the thought of Socrates is undergoing development in the mind of Plato, but it will be natural to regard the development as, in the main, unconscious, and to recognize that no complete separation of the Socratic and the Platonic in the result is possible.

It is certain that on the logical side the thought of Socrates proceeded "as if" the doctrine of Forms expounded in the *Phaedo* were its point of departure. Both Plato and Xenophon bear out the remark of Aristotle that Socrates may fairly be credited with two things, "inductive arguments" and "universal definitions" (*Met. M.*, 1078 *b*27). The "universal definition" is an attempt to formulate precisely the meaning of a universal significant predicate, *i.e.*, to apprehend what the *Phaedo* calls a Form, and it is from the practice of Socrates, who aimed at the clarification of thought about the meaning of moral predicates as the first indispensable step to the improvement of practice, that the theory of logical division and definition, as worked out in Plato's later dialogues and the logical treatises of Aristotle, has arisen.

The "inductive arguments" mean the characteristic attempts

to arrive at such formulations by the consideration of simple and striking concrete illustrations familiar to us from both Xenophon and Plato, the perpetual arguments about "shoemakers and carpenters and fullers," which the fashionable speakers in Plato profess to think vulgar. Induction, on this view of it, is not regarded as a method of proof. Its function is that of suggestion; it puts the meaning of a proposed "definition" forcibly and clearly before the mind. The justification of the definition, then, has to be sought in a consideration of the satisfactoriness of the "consequences," which would follow from its adoption. Socrates himself sought for his "definitions" principally in the sphere in which he was most interested, that of conduct, private and public. As Aristotle says, he concerned himself with the "ethical," character and conduct, not with "nature" at large. This is what Cicero means by saying that he "brought down philosophy from heaven to earth."

Before him cosmology had been the chief topic of interest, after him, the central problem of philosophy was to formulate a rule of life. With him the "practical use of reason" comes by its rights. In this respect Socrates stamped on philosophy a character which it has never lost. The main outlines of his philosophy of conduct are fortunately quite certain, and could be discovered if we had no more material than the Platonic *Apology* and the *Memorabilia* of Xenophon. As the *Apology* tells us, the specific message from God which Socrates brought to his fellow men was that it is the great business of life to practice the "care" or "tendance" (ἐπιμέλεια, θεραπεία), of one's *soul,* to "make one's soul as good as possible," and not to ruin one's life, as most men do, by putting care for the body or for "possessions" before care for the "soul."

The thought which is here fundamental is that of the "soul" (ψυχή) as that which is most truly a man's self. In Greek literature, down to the end of the 5th century, we can trace two main senses of the word ψυχή. (1) It means "the breath of life" which a man parts with in dying. It is this which, in popular superstition, is left as a mere "ghost," or "shade," when the man "himself," his body, has perished. In earlier Ionian science this is identified with the "air" which a man inhales so long as he is alive. (2) In circles influenced by the Orphic religion the soul is thought of as something which has a destiny beyond the grave, but this, too, is something different from the self. It is a sort of stranger inhabiting the body, but having little to do with the conduct of normal life. It "sleeps while the body is active, but wakes when the body sleeps," and reveals itself chiefly in dream and trance. From the beginning of the 4th century we find ψυχή coming at last to mean what "soul" means to us, the normal waking personality, the seat of character and intelligence, "that," as Socrates says in Plato, "in virtue of which we are called wise or foolish, good or bad," and as this usage of the word first appears in writers whom we know to have been influenced by Socrates (Isocrates, Plato and Xenophon), we may fairly ascribe it to his influence. The thought now works out thus. The soul *is* the man (in the later Academic formulation a man *is* "a soul using a body").

Our happiness or well-being, then, depends directly on the goodness or badness of the soul. It is no happiness to possess health, or strength, or wealth, unless we know how to *use* these advantages rightly. If we use them wrongly, they will only be so many means to misery. The reason why hardly any one achieves happiness is not that men do not wish to be happy. No one ever wishes for anything but true good, that is, true happiness, but men miss their happiness, in spite of the universal wish for it, because they do not *know* what it is. They mistake for real good things which are not really good (*e.g.,* unlimited wealth or power). In this sense, "all wrong-doing is involuntary." The first and fundamental requisite for happiness, then, is that men should *know* true good and not confuse it with anything else. The good state of the soul is precisely that state in which it never makes the mistake of taking anything to be good when it is not really good. To "make one's soul as good as possible" thus means to attain the knowledge of good which will prevent us from *using* strength, health, wealth, opportunity, wrongly. If a man has this knowledge, he will always act on it, since to do otherwise would be to prefer known misery to known happiness, and this is impossible. *"All* the virtues are one thing," *knowledge* of good, and all "vice" is one thing, ignorance of true good.

"Popular" goodness—what passes current as virtue—is mostly illusory, because it is mainly a matter of habit, not of assured conviction about good. It breaks down under temptation; but if a man really knew that, *e.g.,* to commit a crime is worse than to suffer loss or pain, or death, no fear of these things would lead him to commit the crime. The professional "sophist," again, claims to be able to teach "goodness," but the claim is shown to be unfounded by the very fact that the sophist treats "goodness" as though it were a neutral "accomplishment" which can be conveyed by mere instructions. Now an accomplishment, or "art," can always be put to either of two uses, a good or a bad, as the physician, for instance, can use his professional knowledge to cure or to kill.

Knowledge of good is the one knowledge of which it is impossible to make an ill use; the possession of it is a guarantee that it will always be used aright. Thus Socrates becomes, as against the relativism of Protagoras, the founder of the doctrine of an absolute morality based on the conception of a felicity which is the good, not of Athenians or Spartans, or even of Greeks, but of man as man. It is not in virtue of our allegiance to a particular city, nor even of our place in a particular historical civilization, but in virtue of our universal humanity, that we have the task of "making the soul as good as possible," or, as Socrates also said, in language influenced by Pythagoreanism, "making it like God."

Politics, from this point of view, does not differ in principle from ethics. The business of the statesman also is the "tendance" of souls, though his task is to aim at making, not only his own soul, but the souls of all his fellow-citizens "as good as possible." The knowledge of good is also the "royal" science or science of governing, the foundation of all statesmanship. The radical vice of ancient democracy, according to Socrates, is that of not demanding evidence of any special knowledge in its leaders; it suffers the destinies of society to be in the hands of men without true insight. Partly this means that by not demanding intellectual qualifications for office, democracy surrenders the control of affairs into the hands of men with no adequate expert knowledge. But this is only a minor part of Socrates' indictment. His main criticism is that though in some departments, at least, the democracy refuses to take the advice of any one but a qualified expert, on the question of the morality and justice of a proposed policy it treats any one citizen's opinion as of equal value with another's.

Even a Themistocles or a Pericles plainly had no knowledge of true statesmanship, as we see from the fact that they neither taught the principles of it to their sons, nor had them taught these principles by others, and if we look at the actual achievements of these men we can see that they were, so to say, good "body-servants" of the *Demos,* they gave it the things which tickled its taste, such as a navy and a commerce; they were no "physicians of the body politic," for they did not promote "righteousness and temperance," the spiritual health of the community. That is, they measured national greatness by wealth and empire, not by character. According to Plato, Socrates maintained that he himself, who abstained all through from active politics, was the one Athenian of the time who deserved the name of statesman. He deserved it because he understood, as the men of action did not, that national, like individual felicity, depends on the knowledge of good which inevitably leads, where it is possessed, to the action which makes the soul "as good as possible."

The well-known Platonic *Republic* may fairly be said to be, on its political side, a picture of the life of a society in which the whole system of social and economic life is based on this Socratic conviction that "politics" is the application to the community at large of the principle that knowledge of the absolutely good is the necessary and sufficient condition of well-being. How far any of the special regulations of Plato's *Utopia* embody actual convictions of Socrates is more than we can say, though it is significant that the *Aspasia* of Aeschines represented Socrates as maintaining

one of Plato's "paradoxes," the capacity of women for war and politics.

The Socratics.—The thought of Socrates has, in the main, been made fruitful for subsequent ages by being taken up and continued in the life-work of Plato. A more temporary influence was exercised by certain other members of the group of Socratic men whom it has become customary to speak of as the "minor" Socratics. The most important of them are Antisthenes of Athens and Eucleides of Megara, with whom the Cynics and Megarians of the 4th and early 3rd centuries are historically connected. With them it is usual also to mention Aristippus of Cyrene, often still spoken of as somehow connected with the Cyrenaic school of the early 3rd century.

It is probable, however, that the current accounts exaggerate the closeness of the connection between these men and the later schools. Aristippus of Cyrene figures in Xenophon's *Memorabilia* simply as a luxurious and refined man of the world who makes it his rule of life to extract personal enjoyment from existence, sitting loose to all attachments which might interfere with his ease and not allowing himself to take root anywhere. The later anecdotes about him bear out this representation. There is no good evidence that he had a philosophy or originated a school. Aristotle ascribes no doctrine to him and never mentions a "Cyrenaic" school of Hedonists, though he could hardly have avoided doing so in his discussions of Hedonism in the *Nicomachean Ethics* if he had known of one. Plutarch expressly describes the Cyrenaics as contemporaries of Epicurus, and all the names of members of the school known to us belong to the time of the successors of Alexander the Great. The one point of doctrine common to them appears to have been that they rejected the notion of a good more permanent than the pleasure of the moment. The supposed connection of Aristippus with them seems to be based on a confusion with his grandson of the same name, who, according to Eusebius, reduced his grandfather's practice to theory.

Eucleides of Megara was a friend both of Socrates and of Plato, who temporarily took refuge with him after the death of Socrates, and, at a later date, dedicated the *Theaetetus* to him. All we know of his teaching is that he held to the Monism of Parmenides, maintaining that nothing is real except "the One," which is also called "wisdom" φρόνησις, "intellect" (νοῦς) and "God" (*D.L.*, ii. 106). The mention of "wisdom" as a synonym for "the One" seems to reveal the influence of Socrates. Most of our notices of Megarians deal with men of a later time, Eubulides, a contemporary of Aristotle, Diodorus Cronus and Stilpo. These men were pugnacious formal logicians famous for their rejection of the notion of "possibility" which is so fundamental in the Aristotelian philosophy. According to them, nothing is possible except the actual. Aristotle resented the criticism so keenly that "sophist" in his terminology appears to be regularly equivalent to "Megarian logician." It is not clear how these ἐριστικοί are connected with the Monism of Eucleides. There are reasons for supposing the puzzling antinomies of Plato's *Parmenides* to be a parody of Megarian logic, and it is a view which has been widely accepted in recent times that they are also meant in Plato's *Sophistes* by the "friends of Forms" who are there contrasted with the materialists and said to maintain that reality consists of a multitude of "incorporal Forms" which can only be apprehended by thought. This identification is, however, uncertain (and, in the present writer's opinion, mistaken).

Antisthenes was a friend of Socrates of long standing, with a marked individuality of his own, and a voluminous writer much admired for his style. He does not appear to have been a "disciple," though he was personally attached to Socrates, and particularly admired his strength of will and mastery of his passions. In philosophy he is chiefly known for two things, his denial of the possibility of making judgments in which the predicate and subject terms are non-identical, and his insistence in ethics on the simplification of life by the reduction of our wants to an indispensable minimum. In virtue of the latter he was commonly regarded as the founder of Cynicism and it is certain that he personally influenced the famous Diogenes and that the later Cynics were in the habit of regarding him as a model man. But it is not clear either that the Cynics of the 4th century were a "sect" or "school" in any real sense of the words, or that the nickname "dog" was ever given to anyone before Diogenes. It was believed in later antiquity that there was a personal feud between Antisthenes and Plato, and it seems certain that one of the works of Antisthenes, called *Sathon*, was a virulent personal attack on Plato. But the ingenuity spent in the 19th century on discovering polemical allusions to Antisthenes in Plato's dialogues seems to have been mostly wasted. According to Plato, the logical paradox that "contradiction is impossible" was maintained by numerous persons in the days of Socrates. Hence it seems unreasonable to detect special allusions to Antisthenes in the frequent references to this paradox in the dialogues.

BIBLIOGRAPHY.—The following may be specially mentioned among recent works: J. Burnet, *Greek Philosophy, Thales to Plato* (1914), *Plato's Phaedo* (1911), *Plato's Euthyphro, Apology of Socrates and Crito* (1924), *Early Greek Philosophy* (3rd ed., 1920), *The Socratic Doctrine of the Soul* in Proceedings of the British Academy (1915–16); A. E. Taylor, *Varia Socratica* (1911), *The Platonic Biography of Socrates*, in Proceedings of the British Academy (1916–17), *Plato, the Man and his Work* (1926); A. Dies, *Autour de Platon* (Paris, 1927); K. Joel, *Der echte und der Xenophontische Sokrates* (1893–1901); H. von Arnim, *Xenophons Memorabilia und Apologie des Sokrates* (Copenhagen, 1923); H. Maier, *Sokrates, sein Werk und seine geschichtliche Stellung* (Tübingen, 1913); U. von Wilamowitz-Moellendorf, *Platon*, vol. i. (1919); A. Busse, *Sokrates* (1914); I. Bruns, *Das literarische Porträt in Altertum* (1896); T. Gomperz, *Griechische Denker*, vol. ii. (Leipzig, 1902; Eng. trans. *Greek Thinkers*, 1901–12); G. Zuccante, *Socrate* (Turin, 1909). Among earlier works, besides the standard histories of ancient philosophy, which, however, need revision in all that relates to Socrates, *see* particularly G. Grote, *History of Greece*, ch. lxviii. (last ed. 1907), and *Plato and the Other Companions of Socrates* (last ed. 1885); W. H. Thompson, *The Phaedrus of Plato* (1868), Appendix I.

SOCRATES, the name of a famous 5th-century church historian. The Ἐκκλησιαστικὴ ἱστορία of Socrates, still extant in seven books, embracing the period from 306 to 439, was written in 439, or within a few years thereafter. He was born about 380 and brought up at Constantinople. He was a "scholasticus" or advocate. His work is dedicated to one Theodorus, who had urged him to write such a history. He had no thorough preparation for the task, and for the period down to the death of Constantius (361) was practically dependent on Rufinus. After his work was finished he became a student of Athanasius's writings and came to see how untrustworthy his guide had been. He accordingly rewrote his first two books (see *H.E.* ii. 1) certainly before 450 and probably before 444 (*see* Geppert, p. 8), and it is only this revision that has reached us. The chief sources from which he drew were: (1) the *Church History*, the *Life of Constantine* and certain theological works of Eusebius; (2) the *Church History* of Rufinus; (3) certain works of Athanasius; (4) the no longer extant Συναγωγὴ τῶν συνοδικῶν of the Macedonian and semi-Arian Sabinus—a collection of acts of councils with commentaries, brought down to the reign of Theodosius I. (this was a main source); (5) the *Constantinopolitan Chronicle*; (6) possibly a collection of imperial biographies; (7) lists of bishops; (8) collections of letters by members of the Arian and orthodox parties.

The theological position of Socrates, so far as he can be said to have had one, is at once disclosed in his unlimited admiration for Origen. All the enemies of the great Alexandrian he regards merely as empty and vain obscurantists; for the orthodoxy of his hero he appeals to Athanasius. Closely connected with his high regard for Origen are his appreciation of science generally and the moderation of his judgment on all dogmatic questions. According to him, Ἑλληνικὴ παιδεία is quite indispensable within the Church; many Greek philosophers were not far from the knowledge of God, as is proved by their triumphant arguments against atheists and gainsayers of divine providence. The apostles did not set themselves against the study of Greek literature and science; Paul had even made a thorough study of them himself. The Scriptures, it is true, contain all that appertains to faith and life, but give no clue to the art of confuting gainsayers. Greek science, therefore, must not be banished from the Church, and the tendency within the Church so to deal with it is wrong. This

point of view was the common one of the majority of educated Christians at that period, and is not to be regarded as exceptionally liberal. The same holds true of the position of Socrates in regard to dogmatic questions.

EDITIONS AND LITERATURE.—Socrates' *History* has been edited by Stephanus (Paris, 1544; Geneva, 1612), Valesius (Paris, 1659 *sqq.*), Reading (Cambridge, 1720), Hussey (Oxford, 1853, reissued by Bright, 1878). It is also to be found in volume lxvii. of Migne's *Patrologia,* and there is an Oxford school edition (1844) after Reading. An English translation, revised by Zenos, is published in the Nicene and post Nicene Fathers, 2nd series, vol. ii.

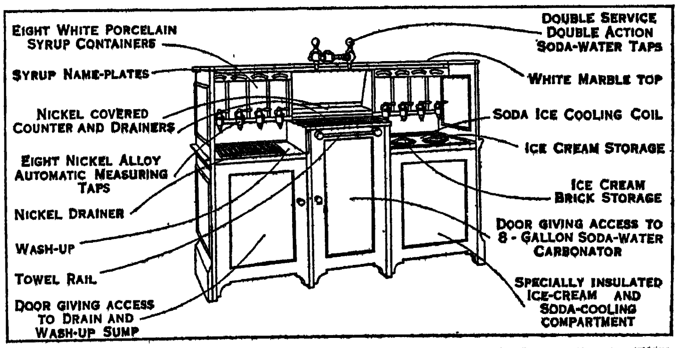
See Harnack, *"Socrates u. Sozomen"* in Herzog-Hauck's *Realencykl.,* 2nd ed., where bibliographical references will be found.

SODA. Under this somewhat loose title are included a number of substances of great industrial importance; viz., sodium carbonate, sodium bicarbonate, sodium hydrate or caustic soda, sodium sesquicarbonate or trona, and soda crystals or washing soda. The bulk of soda compounds is manufactured, but there exist in various parts of the world, notably in Canada, the United States, and East Africa, natural deposits of trona in the form of salt lakes. Washing soda, which is sodium carbonate combined with a proportion of water to form crystals, is a familiar substance; as also is sodium bicarbonate in medical preparations. The remainder of the group provide raw material for other industries and are not commonly met elsewhere. (*See* ALKALI.)

(A. E. H.)

SODA FOUNTAIN. This term was used to designate the equipment from which carbonated water, flavored and sweetened, is drawn and dispensed. An apparatus to serve soda water in a glass or tumbler instead of from a bottle came with the development of carbonating machinery. English and French manufacturers in the period from 1800 to 1825 devised improved equipment for making what was called "soda water." One improvement was a strongly built metal tank, cylindrical in form and holding several gallons of water, in which carbonic gas entered. This "cylinder," as it was called in England, and a "fountain" in the United States, was mounted on a frame and was rocked back and forth so as to increase the saturation of the water by the gas. The cylinder, being portable, was placed under the counter in the shop, and the soda water was drawn through a pipe which had a draft arm above the counter.

The important changes and improvements in the fountain have been made by American manufacturers. About 1855 the marble soda fountain was introduced, the apparatus being a marble box with an ice-chest to cool the coil of pipe and a metal container for the syrups which were drawn from a row of faucets. The early soda fountain changed from time to time as improvements were



REAR OR WORKING SIDE OF A WILSON SODA FOUNTAIN USED IN THE PREPARATION OF SOFT DRINKS

made. At first carbon dioxide was obtained by the interaction of an acid and a carbonate, then the gas was prepared from various sources—from natural gas, collected from brewers' fermenting vats, and from burning coke. The last-named source now supplies most of the carbonic gas, which comes in liquid form in steel tubes for carbonating beverages. Other improvements made in recent years are mainly in perfecting the carbonating machinery, in mechanical or electric refrigeration, in extending the service of the soda fountain, and in simplifying the working of the equipment so that the process or system is more or less automatic.

The present-day standardized soda fountain is built on a steel or iron frame. It resembles a long, narrow metal box, thoroughly insulated and sealed to keep out air and heat, and is divided into many sections and compartments. A 10 ft. fountain unit is commonly equipped with a cooling chamber for soda and ice water, two or three compartments for chipped ice, four cabinets for holding 5 gal. of bulk ice cream in cans and two cabinets for 5 gal. of brick ice cream, six syrup jars with pumps, four crushed fruit jars, one or two dry cold storage compartments for fresh fruits, milk or bottled goods, and two open sections (one at each end of the counter) with drainboard, sink, tumbler rinsers, a dish and spoon vat.

Soda fountains are made in two styles, the counter fountain and the back bar fountain. The latter has a so-called bar back of the counter, a structure 3 or 4 ft. high with a polished wood, tile or marble cornice supported on the two sides by columns of similar materials to match, with shelves for a display of glassware or candy, and with a large mirror in the centre.

At the present time the soda fountain is to be found everywhere in America: in most drug and candy stores, in department stores, in motion picture houses and at the road-side stands and inns for the patronage of tourists and the travelling public. The "soda parlor," as it was originally called, has developed into the soda fountain luncheonette—a place where not only an infinite variety of drinks, but foods such as soup, bouillon, sandwiches, salads, pastry and cake, are served. It is estimated there are from 90,000 to 100,000 fountains in the United States. The number of fountains in the European countries is rather small, probably not more than 1,000, and the demand has increased slowly. The soda fountain is becoming popular in Canada and in South American countries, and in the Australian Commonwealth where some 2,500 are now in use. (L. J. V.)

SODALITE, a member of the group of rock-forming minerals comprising the following isomorphous species:—

Sodalite	$Na_4(AlCl)Al_2(SiO_4)_3$
Haüynite	$(Na_2Ca)_2(NaSO_4{\cdot}Al)Al_2(SiO_4)_3$
Noselite	$Na_4(NaSO_4{\cdot}Al)Al_2(SiO_4)_3$
Lazurite	$Na_4(NaS_3{\cdot}Al)Al_2(SiO_4)_3$

These are sodium (or calcium) aluminium silicates, with chloride, sulphate, or sulphide. In their orthosilicate formulae, as above written, and in their cubic crystalline form they present a certain resemblance to the members of the garnet group. Crystals usually have the form of the rhombic dodecahedron, and are often twinned with interpenetration on an octahedral plane. They are white, or often blue in colour, and have a vitreous lustre. The hardness is $5\frac{1}{2}$, the specific gravity 2·2–2·4. These minerals are characteristic constituents of igneous rocks rich in soda, and they also occur in metamorphic limestones.

The species sodalite (so named because it contains soda) occurs as well-formed, colourless crystals in the ejected limestone blocks of Monte Somma, Vesuvius. In the elaeolite-syenite of Dungannon in Ontario bright sky-blue material has been quarried for use as an ornamental stone. Haüynite, or haüyne (named after R. J. Haüy), occurs as bright blue crystals and grains in the lavas of Vesuvius, Rome, the Eifel, etc. Noselite, or nosean, is found as greyish crystals in the sanidine bombs of the Eifel. Lazurite is an important constituent, together with some haüynite and sodalite, of lapis-lazuli (*q.v.*). (L. J. S.)

SODA WATER: *see* AERATED WATERS.

SODDY, FREDERICK (1877–), British scientist, was born at Eastbourne, Sussex, on Sept. 2, 1877, and was educated at Eastbourne college, the University college of Wales, Aberystwyth and Merton college, Oxford. From 1900–2 he held the post of demonstrator of chemistry at the McGill university, Montreal, where he carried out research work on radioactivity with Sir E. Rutherford, and for the next two years he worked under Ramsay at University college, London, becoming in 1904 lecturer in physical chemistry and radioactivity at the University of Glasgow. Ten years later he went to Aberdeen university as professor of chemistry, but he left there in 1919 to become Lee's professor of inorganic and physical chemistry in the university of Oxford. He made many valuable contributions to the science

of radioactivity, and with Sir E. Rutherford he developed the disintegration theory of the radioactive elements. As a result of his study of the disintegration series of the radio-elements Soddy concluded that certain elements should exist in two or more forms which may have different atomic weights, but are indistinguishable and inseparable chemically; these forms he called "isotopes." This theory, which probably constitutes Soddy's main contribution to scientific knowledge, was first published in 1912 and has since been brilliantly confirmed in many directions. He was awarded the Nobel Prize for chemistry in 1921. He was elected F.R.S. in 1910 and was a member of many British and foreign scientific societies, being president of the Röntgen Society 1905–6. (*See* X-RAYS.)

His numerous scientific publications, chiefly on radioactivity, include *Radioactivity* (1904); *The Interpretation of Radium* (1909) revised and enlarged by a section on the "Structure of the Atom" (1920); *Chemistry of the Radioactive Elements* (Part I., 1920; Part II., 1914); *Matter and Energy* (1912); *Science and Life* (1920); *Cartesian Economics* (1922); *Inversion of Science* (1924).

SÖDERBLOM, NATHAN (1866–), Swedish ecclesiastic, was born in Trönö on Jan. 15, 1866, and educated at the University of Uppsala. After the Lambeth Conference in 1908, Söderblom worked with success to secure an approach to "evangelical catholicity" among various Christian societies, and played an important part in the preparations for the universal Christian Conference on Life and Work held at Stockholm in Aug. 1925, in which he was one of the leaders. He had been appointed archbishop of Uppsala in 1914.

SÖDERHAMN, a seaport of Sweden, in the district (*län*) of Gefleborg, on an inlet of the Gulf of Bothnia, near the mouth of the Ljasne River, 183 m. N. by W. of Stockholm by rail. Pop. (1928), 11,680. Vessels drawing 15 ft. have access to Branthäll. The harbour is usually ice-bound for some four months in winter.

SÖDERTÄLJE, a town of Sweden, in the district (*län*) of Stockholm, 23 m. W.S.W. of Stockholm by rail. Pop. (1928), 14,811. It is on a bay of Lake Mälar, here connected with the Baltic by the Södertälge canal, $1\frac{1}{4}$ m. in length, with a minimum depth of 10 ft. This is on the route followed by the Göta Canal steamers between Stockholm and Gothenburg; it was opened in 1819, though a canal was begun here in the 15th century at the instigation of Engelbrecht. The town contains a church, believed to date from *c.* 1100.

SODIUM [symbol Na; atomic number 11; atomic weight 23·00 (O=16)], a chemical element belonging to the group of alkali metals. It is abundantly and widely diffused in nature, but always in combination. Sodium chloride, or common salt (*q.v.*), is exceedingly common, being the chief salt present in sea-water, besides occurring in extensive stratified deposits. Sodium carbonates are also widely dispersed in nature, forming constituents of many mineral waters, and occurring as principal saline components in natron or trona lakes, as efflorescences in Lower Egypt, Persia and China, and as urao in Mexico, Colombia and Venezuela. The solid crusts found at the bottom of the salt lakes of the Araxes plain in Armenia contain about 16% of carbonate and 80% of sulphate. In Colombia there occurs a double salt, $Na_2CO_3 \cdot CaCO_3 \cdot 5H_2O$, known as gay-lussite. In Wyoming, California and Nevada enormous deposits of carbonates, mixed in some cases with sulphate and with chloride, occur. Vast areas of the steppes in Hungary contain sodium carbonate in the soil. Natural sulphate occurs in an anhydrous condition as thenardite, Na_2SO_4, at Tarapaca, Chile, and in the rock-salt deposits at Espartinas near Aranjuez, Spain. Hydrated sulphates occur at several localities in certain provinces of Spain, and at Mühlingen in Aargau, and copious deposits of glauberite, the double sulphate of sodium and calcium, are met with in the salt-mines of Villarrubia in Spain, at Stassfurt, and in the province of Tarapaca, Chile, etc. A native nitrate of soda is obtained in great abundance in the district of Atacama and in Tarapaca, and was formerly imported into Europe in enormous quantities as cubic nitre for the preparation of saltpetre. Cryolite, a fluoride of aluminium and sodium, is extensively mined in Greenland and elsewhere for industrial purposes. These form the principal natural sources of sodium compounds—the chloride as rock salt and in sea-water being of such predominating importance as quite to outweigh all the others. But it is questionable whether, taken altogether, the mass of sodium they represent is as much as that disseminated throughout the rocky crust in the form of soda felspar (*i.e.,* as silicate of soda) and in other soda-containing rocks. From this source all soils derive small proportions of sodium in soluble forms, hence the ashes of plants, although they preferably imbibe potassium salts, contain traces and sometimes notable quantities of sodium salts, which also form essential ingredients in all animal juices.

Although many sodium compounds have been known from very remote times, the element was not isolated until 1807, when Sir H. Davy obtained it by electrolysing caustic soda. This method was followed by that proposed by Gay-Lussac and Thénard, who decomposed molten caustic soda with red-hot iron; and this in turn was succeeded by Brunner's process of igniting sodium carbonate with charcoal. In spite of many attempts, however, the metal could not be cheaply produced until electrolytic methods were perfected, and that patented by Castner in 1890 formed the basis of subsequent successful methods. If sodium chloride is used, there are several disadvantages: the fused salt and both the products of its electrolysis exert a destructive action upon containing vessels, and, further, the boiling point of the metal (877°) is inconveniently near the melting point (775°) of the salt. Borchers endeavoured to contend against the first difficulty by employing an iron cathode vessel and a chamotte (fireclay) anode chamber united by a specially constructed water-cooled joint. The other difficulty is to some extent met by using a mixture of sodium, strontium and potassium chlorides, which melts at a lower temperature than the pure chloride. In Castner's process (as employed at Oldbury and Niagara Falls and in Germany) fused caustic soda is electrolysed. The apparatus consists of an iron cylinder heated by gas rings below, with a narrower cylinder beneath, through which passes upwards a stout iron cathode rod cemented in place by caustic soda solidified in the narrower vessel. Iron anodes are suspended around the cathode, and between the two is a cylinder of iron gauze at the bottom with a sheet-iron continuation above, the latter being provided with a movable cover. During electrolysis, oxygen is evolved at the anode and escapes from the outer vessel, while the sodium deposited in globules on the cathode floats upwards into the iron cylinder, within which it accumulates, and from which it may be removed at intervals by means of a perforated iron ladle, the fused salt, but not the metal, being able to pass freely through the perforations. The sodium is then cast into moulds. Sodium hydroxide has certain advantages compared with chloride, although it is more costly; its fusing-point is only 320° C, and no anode chlorine is produced, so that both containing vessel and anode may be of iron, and no porous partition is necessary.

Properties.—Metallic sodium possesses a silvery lustre, but on exposure to moist air the surface is rapidly dulled by a layer of the hydroxide. It may be obtained crystalline by melting it in a sealed tube containing hydrogen, allowing it to cool partially, and then pouring off the liquid portion. The specific gravity is 0·971 at 20° C. At ordinary temperatures the metal has the consistency of wax and can be readily cut; on cooling it hardens. On heating it melts at 97° to a liquid resembling mercury, and boils at about 880° C, yielding a vapour, colourless in thin layers but a peculiar purple, with a greenish fluorescence, when viewed through thick layers. (For the optics of sodium vapour *see* R. W. Wood, *Physical Optics.*) Sodium ranks fourth to silver, copper and gold as a conductor of electricity and heat, and is the most electropositive metal with the exception of caesium, rubidium and potassium.

The metal is very reactive chemically. Exposed to moist air it rapidly oxidizes to the hydroxide; and it burns on heating in air with a yellow flame, yielding the monoxide and dioxide; in extremely dry air it is inert. (*See* DRYNESS, CHEMICAL.) A fragment thrown on the surface of water rapidly disengages hy-

drogen, which gas, however, does not inflame, as happens with potassium; but inflammation occurs if hot water be used, or if the metal be dropped on moist filter paper. Sodium combines directly, sometimes very energetically, with most non-metallic elements. It dissolves in liquid ammonia giving a blue solution in which its molecular weight is 23 (Kraus)—*i.e.*, the molecules are monatomic. It also combines with dry ammonia at 300–400° to form sodamide, $NaNH_2$, a white waxy mass when pure, which melts at 155°. Heated in a current of carbon dioxide sodamide yields caustic soda and cyanamide, and with nitrous oxide it gives sodium azoimide; it deflagrates with lead or silver nitrate and explodes with potassium chlorate. Sodamide was introduced by Claisen as a condensing agent in organic chemistry, and has since been applied in many directions. Sodium is largely employed in the manufacture of cyanides and was formerly used in reduction processes leading to the isolation of such elements as magnesium, silicon, boron, aluminium, etc.; it also finds application in organic chemistry. With potassium it forms a liquid alloy resembling mercury, which has been employed in high temperature thermometers. (*See* THERMOMETRY.)

COMPOUNDS

In its chemical combinations sodium is usually univalent; its salts are generally soluble in water, the least soluble being the pyroantimoniate, the dihydroxytartrate, and the triple nitrite $5Bi(NO_2)_3$, $9CsNO_2$, $6NaNO_2$.

Sodium hydride, NaH, is a crystalline substance obtained directly from sodium and hydrogen at about 360°. It burns when heated in dry air, and ignites in moist air; it is decomposed by water, giving caustic soda and hydrogen. Dry carbon dioxide is decomposed by it, free carbon being produced; moist carbon dioxide, on the other hand, gives sodium formate.

Several oxides have been described, but only two are important. The monoxide, Na_2O, is obtained by heating the metal above 180° in a limited amount of slightly moist oxygen. It forms a grey mass, which melts at a red heat and violently combines with water to give the hydroxide. The hydroxide or caustic soda, NaOH, is usually manufactured from the carbonate or by electrolysis of salt solution. (*See* ALKALI MANUFACTURE.) When anhydrous it is a colourless opaque solid which melts at 318°, and volatilizes with partial decomposition at a white heat. It is very soluble in water, yielding a strongly alkaline solution; it also dissolves in alcohol. It absorbs moisture and carbon dioxide from the atmosphere. Several hydrates are known; plus $2NaOH{\cdot}7H_2O$ is obtained crystalline by cooling concentrated solutions, $NaOH{\cdot}H_2O$ by allowing the very concentrated solution to crystallise while hot, and $NaOH{\cdot}2H_2O$ from a solution in 96·8% alcohol.

Sodium peroxide, Na_2O_2, is formed when the metal is heated in an excess of air or oxygen. In practice the metal is placed on aluminium trays traversing an iron tube heated to 300°, through which a current of air, freed from moisture and carbon dioxide, is passed; the process is made continuous, and the product contains about 93% Na_2O_2. When pure, sodium peroxide has a faint yellowish tinge, but on exposure it whitens. When dissolved in water it yields some NaOH and H_2O_2, but from a cold solution $Na_2O_2{\cdot}8H_2O$ separates as large tabular hexagonal crystals, and this is also obtained by precipitating a mixture of caustic soda and hydrogen peroxide solutions with alcohol. Acids yield a sodium salt and free oxygen or hydrogen peroxide; with carbon dioxide it gives sodium carbonate and free oxygen; carbon monoxide gives the carbonate; whilst nitrous and nitric oxides give the nitrate. A solution in hydrochloric acid, consisting of the chloride and hydrogen peroxide, is used for bleaching straw under the name of soda-bleach; with calcium or magnesium chlorides this solution gives a solid product which, when dissolved in water, is used for the same purpose. Sodium peroxide is chiefly employed as an oxidizing agent, being used in mineral analysis and in various organic preparations; it readily burns paper, wood, etc., but does not evolve oxygen unless heated to a high temperature. Sodyl hydroxide, $NaHO_2$, is said to exist in two forms: one, Na·O·OH, obtained from hydrogen peroxide and sodium ethoxide; the other, O:Na·OH, from absolute alcohol and sodium peroxide at 0°. They are strong oxidizing agents and yield alkaline solutions which readily evolve oxygen on heating.

Generally speaking, sodium salts closely resemble the corresponding potassium salts, and their methods of preparation are usually the same. For sodium salts not mentioned below reference should be made to articles wherein the *acid* is treated, unless otherwise indicated.

Sodium combines directly with the halogens to form salts which are soluble in water and crystallize in the cubic system. The fluoride, NaF, is sparingly soluble in water (1 part in 25). For the chloride see SALT. The bromide and iodide crystallize from hot solutions in anhydrous cubes; from solutions at ordinary temperatures in monoclinic prisms with $2H_2O$; and at low temperatures with $5H_2O$. The iodide differs from the other haloid salts in separating from solution in alcohols with "alcohol of crystallization." Sodium sulphide, Na_2S, obtained by saturating a caustic soda solution with sulphuretted hydrogen and adding an equivalent of alkali, is employed in the manufacture of soluble soda glass. Sodium sulphite, Na_2SO_3, which is employed as an antichlor, is prepared (with $7H_2O$) by saturating a solution of sodium carbonate with sulphur dioxide, adding another equivalent of carbonate and crystallizing. The anhydrous salt may be prepared by heating a saturated solution of the hydrated salt. The acid sulphite, $NaHSO_3$, or probably $Na_2S_2O_5$ (*i.e.*, metabisulphite) when solid, obtained by saturating a cold solution of the carbonate with sulphur dioxide and precipitating by alcohol, is employed for sterilizing beer casks. Sodium sulphate, Na_2SO_4, known in the hydrated condition (with $10H_2O$) as Glauber's salt, is manufactured in large quantities for conversion into the carbonate or soda. (*See* ALKALI MANUFACTURE.) For many years sodium was not known to form an alum (*q.v.*), but if a supersaturated solution of sodium and aluminium sulphates is allowed to crystallise below 20° C, the alum $Na_2SO_4{\cdot}Al_2(SO_4)_3{\cdot}24H_2O$ is obtained, higher temperatures giving monoclinic crystals. The acid sulphate, $NaHSO_4$, also known as bisulphate of soda, is obtained as large asymmetric prisms by crystallizing a solution of equivalent quantities of the normal sulphate and sulphuric acid above 50°.

The manufacture of sodium carbonate, commonly called soda, is treated under ALKALI MANUFACTURE. The anhydrous salt is a colourless powder or porous mass, having an alkaline taste and reaction. It melts at 852°. On solution in water, heat is evolved and hydrates formed. Common washing soda or soda-crystals is the decahydrate, $Na_2CO_3{\cdot}10H_2O$, which appears as large clear monoclinic crystals. On exposure, it loses water and gives the monohydrate, $Na_2CO_3{\cdot}H_2O$, a white powder sold as "crystal carbonate"; this substance, which is also formed on heating the decahydrate to 34°, crystallizes in the rhombic system. Both these hydrates occur in the mineral kingdom, the former as natron and the latter as thermonatrite. The heptahydrate, $Na_2CO_3{\cdot}7H_2O$, is obtained by crystallizing a warm saturated solution in a vacuum; it appears to be dimorphous. The acid carbonate or bicarbonate of soda, $NaHCO_3$, is produced in the ammonia-soda process for alkali manufacture. Another acid carbonate,

$$Na_2CO_3{\cdot}NaHCO_3{\cdot}2H_2O,$$

is the mineral trona or urao. We may here notice the "percarbonates," obtained by acting with gaseous or solid carbon dioxide on Na_2O_2 or $NaHO_2$ at low temperatures. For sodium nitrite *see* NITROGEN; for sodium nitrate *see* SALTPETRE; for the cyanide *see* PRUSSIC ACID; and for the borate *see* BORAX.

Of the sodium silicates the most important is the mixture known as soluble soda glass formed by calcining a mixture of white sand, soda-ash and charcoal, or by dissolving silica in hot caustic soda under pressure. It is a colourless transparent glass mass, which dissolves in boiling water to form a thick liquid. It is employed in certain printing processes, as a cement for artificial stone and for mending glass, porcelain, etc., and also for making the so-called silicated soaps. (*See* SOAP.) Sodium silicates containing excess of silica in solution are useful adhesives.

Sodium is most distinctly recognized by the yellow coloration which volatile salts impart to a Bunsen flame, or, better, by its emission spectrum which has a line (double), the Fraunhofer D

line, in the yellow (the wave-lengths are 5896 and 5890). It is estimated as sulphate by evaporation of its solutions with concentrated sulphuric acid, or as the sparingly soluble triple nitrite, $5Bi(NO_2)_3,9CaNO_2,6NaNO_2$, or, in 50% alcohol, as the triple acetate, $3NO_2(C_2H_3O_2)_2$, $Mg(C_2H_3O_2)_2$, $Na(C_2H_3O_2)$, $9H_2O$.

MEDICINE

Pharmacology.—The metal sodium is not used in medicine, but many of its salts are employed. Besides *liquor sodii ethylatis* the following salts and preparations are used in the British Pharmacopoeia. (1) *Sodii carbonis,* known as washing soda which on heating yields *sodii carbonis exsiccatus; sodii bicarbonas,* from which is made *trochiscus sodii bicarbonatis.* (2) *Sodii phosphas.* From sodium phosphate are made *sodii phosphas effervescens* and *sodii hypophosphis.* (*See* PHOSPHORUS.) (3) *Sodii sulphas* (Glauber's salt), with its sub-preparation *sodii sulphas effervescens.* (4) *Soda tartarata* (Rochelle salt), a tartrate of sodium and potassium, from which is made *pulvis sodae tartaratae effervescens,* known as Seidlitz powder. (5) *Sodii citro-tartras effervescens,* a mixture of sugar, sodium bicarbonate, citric and tartaric acids. (6) *Sodii chloridum,* common salt. (7) *Sodii sulphis.*

For *sodii bromidum, iodidum* and *salicylatum* see BROMINE, IODINE and SALICYLIC ACID respectively. For *sodii arsenas* and *cacodylate* see ARSENIC. *Sapo durus* (hard soap) is a compound of sodium with olive oil, and *sapo animalis* (curd soap) is chiefly sodium stearate.

Poisoning by caustic soda is rare; the symptoms and treatment are the same as described under POTASSIUM. The salts of sodium resemble potassium in their action on the alimentary tract, but they are much more slowly absorbed, and much less diffusible; therefore considerable amounts may reach the small intestine and there act as saline purgatives. They are slowly absorbed into the blood, and are a natural constituent of the blood plasma, which derives them from the food. Sodium is excreted by all the mucous surfaces and by the liver and kidneys. On the latter they act as diuretics, but less powerfully than potassium, increasing the flow of water and the output of urea and rendering the urine less acid.

Therapeutics: External Use.—The liquor sodii ethylatis is a powerful caustic and is used to destroy small naevi and warts. A lotion of sodium bicarbonate is useful to allay itching. Solutions of sodium sulphite are used as mild antiparasitics. *Internal Use.*—Sodium chloride is occasionally used in warm water as an emetic, and injections of it into the rectum as a treatment for thread worms. A 0.9% solution forms what is termed normal saline solution, which is frequently injected into the tissues in cases of collapse, haemorrhage and diarrhoea. It forms a valuable treatment in diabetic coma and eclampsia, acting by diluting the toxins in the blood. From this has developed the intramuscular injection of diluted sea-water in the treatment of gastro-enteritis, anaemia and various skin affections. Sodium chloride is an important constituent of the waters of Homburg, Weisbaden, Nauheim and Kissingen. Sodium bicarbonate is one of our most useful gastric sedatives and antacids, relieving pain in hyperchloridia. It is the constituent of most stomachic mixtures. Effervescent soda water is a mild gastric sedative. Sodium phosphate and sulphate are cholagogue purgatives and are used in the treatment of gall-stones. The sulphate is the chief constituent of Marienbad and Carlsbad waters. Large doses of these salts are used to remove fluid in dropsy. Soda tartarate is purgative and diuretic, as is the citro-tartarate. These purgative sodium salts are most useful in the treatment of chronic constipation, and of the constipation associated with gout and hepatic dyspepsia. They should be dissolved in warm water and taken in the morning, fasting. In visceral gout and chronic catarrhal conditions of the stomach a course of alkaline waters is distinctly beneficial. Sodium salts have not the depressant effect so marked in those of potassium.

SODOMA, IL (1477–1549), the name given to the Italian painter Giovanni Antonio Bazzi. He was born at Vercelli in Lombardy in 1477. His first master was Martino Spanzotto, by whom one signed picture is known. Acquiring thus the strong colouring and other distinctive marks of the Lombard school, he was brought to Siena in 1501 by some agents of the Spannocchi family; and, as the bulk of his professional life was passed in this Tuscan city, he counts as a member of the Sienese school, although not affined to it in point of style. He does not seem to have been a student in Siena, apart from some attention which he bestowed upon the sculptures of Jacopo della Quercia. With Pinturicchio, he was one of the first to establish there the matured style of the *Cinquecento.* His earliest works of repute are a series of 31 paintings executed from 1505 to 1508 in the Benedictine monastery of Monte Oliveto, on the road from Siena to Rome, illustrating the life of St. Benedict, in continuation of the series which Luca Signorelli had begun in 1498. Hence he was invited to Rome by the celebrated Sienese merchant Agostino Chigi, and was employed by Pope Julius II. in the Camera della Segnatura in the Vatican. He executed two great compositions and various ornaments and grotesques. The latter are still extant; but the larger works did not satisfy the pope, who engaged Raphael to substitute his "Justice," "Poetry" and "Theology." In the Villa Farnesina Bazzi painted some frescoes; "Alexander in the Tent of Darius" and the "Nuptials of the Conqueror with Roxana" (by some considered his masterpiece) are more particularly noticed. Bazzi afterwards returned to Siena and later went in quest of work to Pisa, Volterra and Lucca. From Lucca he returned to Siena, not long before his death, which took place on Feb. 14, 1549. He had squandered his property and is said (rather dubiously) to have died in penury in the great hospital of Siena.

It is uncertain whether Bazzi was a pupil of Leonardo da Vinci, though Morelli (in his *Italian Pictures in German Galleries*) speaks of his having "only ripened into an artist during the two years (1498–1500) he spent at Milan with Leonardo"; and some critics see in Bazzi's "Madonna" in the Brera (if it is really by Bazzi) the direct influence of this master.

His most celebrated works are in Siena. In S. Domenico, in the chapel of St. Catherine of Siena, are two frescoes painted in 1526, showing Catherine in ecstasy, and fainting as she is about to receive the Eucharist from an angel—a beautiful and pathetic treatment. In the oratory of S. Bernardino, scenes from the history of the Madonna—the "Visitation" (1518) and the "Assumption" (1532)—are noticeable. In the Academy are the "Deposition from the Cross" (1513) and "Christ Scourged"; by many critics one or other of these paintings is regarded as Bazzi's masterpiece. In the choir of the cathedral at Pisa is the "Sacrifice of Abraham," and in the Uffizi Gallery of Florence a "St. Sebastien."

See *Giovanni Antonio Bazzi,* by Robert H. Hobart Cust (1906), which contains a full bibliography.

SODOM AND GOMORRAH, two of the five "cities of the plain" in the Dead sea region, the others being Admah, Zeboim and Zoar (Bela) (Gen. xiii., xiv., xix.). They were destroyed by a rain of "fire and brimstone." Various identifications of these cities with modern sites have been suggested, based mainly on similarity of names. Jebel Usdum, for instance, the salt hill at the south-west corner of the Dead sea, has radically the same name as Sodom, which, indeed, may have been situated in its neighbourhood. The element of history in the narrative of the "cities of the plain" is as difficult to assess as the sites are to determine. A scientific explanation of the catastrophe is not excluded. (*See* DEAD SEA.)

See Report of the Joint Expedition of the Xenia Seminary and the American School of Oriental Research at Jerusalem to seek for the cities of the Plain in *Bibliotheca Sacra* (1924). (E. Ro.)

SODOR AND MAN, bishopric of the Church of England which includes the Isle of Man and adjacent isles. In 1154 the diocese of Sodor was formed to include the Hebrides and other islands west of Scotland (Norse *Suðreyjar,* Sudreys, or southern isles, in distinction from *Norðreyjar,* the northern isles of Orkney and Shetland) and the Isle of Man. It was in the archdiocese of Trondhjem in Norway. (*See* MAN, ISLE OF.) The Norwegian connection was broken in 1266, and in 1334 Man was detached from the Scottish islands. The cathedral of Sodor was on St. Patrick's isle at Peel (*q.v.*). The termination "and Man" seems to have been added in ignorance in the 17th century by a legal draughtsman. The see, while for some purposes in the archdiocese of York, has its own convocation; its relationship to the

scheme of election of bishops to the House of Lords is not clear.

SOEST, a town in the Prussian province of Westphalia, 33 m. E. of Dortmund, on the main railway Cologne-Elberfeld-Berlin. Pop. (1925) 21,038. Mentioned in documents as early as the 9th century, Soest was one of the largest and most important Hanseatic towns in the middle ages. It was one of the chief emporiums on the early trading route between Westphalia and Lower Saxony. Its code of municipal laws (*Schran; jus susatense*), dating from 1144 to 1165, was one of the earliest and best, and served as a model even to Lübeck. On the fall of Henry the Lion, Soest passed with the rest of Angria to Cologne. In the 15th century the strife between the townsmen and the archbishops broke out in open war, and in 1444 the strong fortifications of the town withstood a long siege. Papal intervention ended the strife, and Soest was permitted to remain under the protection of the dukes of Cleves. The prosperity of the town waned in more modern times: in 1763 its population was only 3,800; in 1816 it was 6,687. Of its churches the most striking are St. Peter's, the Wiesenkirche, a gem of Gothic architecture, Maria zur Höhe with beautiful mural frescoes, founded in 1314 and restored in 1850–1852, and the Roman Catholic cathedral, founded in the 10th century by Bruno, brother of Otto the Great (the present building was erected in the 12th century). Remains of the broad wall and one of the gates remain; but the thirty-six strong towers which once defended the town have disappeared. The town-hall (1701) contains valuable archives; the gymnasium was founded in 1534, through the instrumentality of Melanchthon. Iron-working, the manufacture of soap, sugar, marmalade, machinery, lamps, cigars, bricks and tiles, linen-spinning and brewing, together with market-gardening in the neighbourhood, and trade in timber and grain are the leading industries.

SOFALA, a Portuguese seaport on the east coast of Africa, at the mouth of a river of the same name, in 20° 12′ S. Pop. (1927) 18 Europeans and 21,015 natives. Its trade declined after the establishment of Beira (*q.v.*) a little to the north in 1890. The harbour, once capable of holding 100 large vessels, is silting up and is obstructed by a bar. Previous to its conquest by the Portuguese in 1505 Sofala was the chief town of a wealthy Mohammedan state, Arabs having established themselves there in the 12th century or earlier. At one time it formed part of the sultanate of Kilwa (*q.v.*). Pero de Covilhão was attracted thither in 1489 by the reports of gold-mines. In 1505 Pero de Anhaya sailed up the river and later raised a fortress (San Gaetano) at its mouth. Portuguese settlement dates from that time. The first governors of the Portuguese East African possessions were entitled captains of Sofala. (*See* PORTUGUESE EAST AFRICA.) Thomé Lopes who accompanied Vasco da Gama to India in 1502, identifies Sofala with Solomon's Ophir but this is untenable. The small island of Chiloane with a good harbour, 40 m. S. of Sofala has been colonized from Sofala (the township being named Chingune) as has also the island Santa Carolina, in the Bazaruto archipelago. Chiloane has good anchorage and is a trading settlement.

See G. McC. Theal's *Records of South Eastern Africa*, 1898–1903; Sir R. Burton's notes to his edition of *Camoens; Delagoa Bay Directory* (1927); *South and East Africa Year Book and Guide* (annually).

SOFFIONI or **SUFFIONI,** a name applied in Italy to certain volcanic vents which emit jets of steam, generally associated with hydrogen sulphide and carbon dioxide, sometimes also with a little ammonia and marsh-gas. The soffioni are usually arranged in groups, and are best represented in the Maremma of Tuscany, where they contain a small proportion of boric acid, for which they are utilized industrially. (*See* FUMAROLE.)

SOFIA (sō-fē′ah), capital of Bulgaria, in an upland plain, about 1,700 ft. above sea-level, between the Western Balkans on the north and Mt. Vitoš on the south. Pop. (1926), 213,162. Two small tributaries of the river Isker, the Perlovetz and the Eleshnitza or Boyana, flow respectively on the east and west sides of the town. Since 1880 the city has been entirely renovated in the "European" style. The oldest building in Sofia is the little round chapel of St. George in the Jewish quarter—originally a Roman bath. Of the principal mosques the large Buyuk Djamía, with nine metal cupolas, has become the National Museum; the Tcherna Djamía or Black Mosque, formerly used as a prison, has been transformed into a church; the Banyabashi Djamía, with its picturesque minaret, is still used by Muslim worshippers. Close to the last-named, in the centre of the town, are the public baths with hot springs (temperature 117° F). The old cathedral of Sveta Nedelya (formerly Sveti Kral), in which the remains of the Serbian king Stefan Uroš II. are preserved, was wrecked by an infernal machine on April 16, 1925, but since rebuilt. The ruined church of Saint Sofia (12th century) contains interesting frescoes. The new cathedral of Alexander Nevski was built as a memorial to the Russians fallen in 1877–78. The palace, occupying the site of the Turkish konak was built by Prince Alexander in 1880–82, and enlarged by King Ferdinand. The city is well drained and has a good water supply; it is lighted by electricity and has an electric tram system. It contains breweries, flour-mills, tanneries, sugar, tobacco, cloth and silk factories, and exports skins, cloth, cocoons, cereals, attar of roses, dried fruit, etc. Sofia forms the centre of a railway system radiating to Constantinople (300 m.), Belgrade (206 m.) and central Europe, Varna, Rustchuk and the Danube, and Kiustendil. The climate is healthy; owing to the elevated situation it is somewhat cold, and is liable to sudden diurnal and seasonal changes; the temperature in January sometimes falls to 4° F below zero and in August rises to 100°. The population, which is mainly Bulgarian, was only 20,501 in 1881. It grew very rapidly after the Balkan and European wars, owing to the influx of refugees.

History.—The colony of Serdica, founded here by the emperor Trajan, became a Roman provincial town of considerable importance in the 3rd and 4th centuries A.D., and was a favourite residence of Constantine the Great. Serdica was burnt by the Huns in A.D. 447; few traces remain of the Roman city, but more than 100 types of its coins attest its importance. The town was taken by the Bulgarians under Krum in A.D. 809; the name Serdica was converted into Sredetz by the Slavs, who associated it with *sreda* (middle), and the Slavonic form subsequently became the Byzantine Triaditza. The name Sofia, which came into use towards the end of the 14th century, is derived from the early mediaeval church of St. Sophia. The town successfully resisted the attacks of the emperor Basil II. in 987; between 1018 and 1186, under Byzantine rule, it served as a frontier fortress. During this period Petchenegs were settled around Sofia; these are probably the ancestors of the modern Šops (*see* PETCHENEGS). In 1382 Sofia was captured by the Turks; in 1443 it was for a brief time occupied by the Hungarians under John Hunyady. Under Turkish rule the city was for nearly four centuries the residence of the beylerbey or governor-general of the whole Balkan peninsula except Bosnia and the Morea. During this period the population was mainly Turkish; in 1553 the town possessed 11 large and 100 small mosques. It was occupied by Russian troops in 1829 and 1878. Though less central than Philippopolis and less renowned in Bulgarian history than Trnovo, Sofia was selected as the capital of the newly-created Bulgarian State in view of its strategical position, which commands the routes to Constantinople, Belgrade, Macedonia and the Danube.

SOFT DRINKS, a term widely used in the United States and elsewhere to designate non-alcoholic drinks generally, but particularly beverages that are carbonated (aerated) and flavoured, including ginger ale. (*See* CARBONATED BEVERAGES.) The term likewise embraces mild cereal beverages, cider, grape juice and other non-carbonated beverages which have natural or synthetic flavouring.

SOGDIANA, a province of the Achaemenian empire (O. Pers. *Sughuda*), corresponding to the modern districts of Samarkand and Bukhara; it lay north of Bactriana between the Oxus and the Iaxartes, and embraced the fertile valley of the Zerafshan (anc. Polytimetus). Under the Greeks Sogdiana was united in one satrapy with Bactria, and subsequently it formed part of the Bactrian Greek kingdom till the Scythians (*see* SCYTHIA) occupied it in the middle of the 2nd century B.C. The valley of the Zerafshan about Samarkand retained even in the middle ages the name of the Soghd of Samarkand.

SOGNE FJORD, an inlet of the west coast of Norway, penetrating 136 m. eastward into the mainland. It is the longest fjord in Norway, and the deepest, approaching 700 fathoms in some parts. Sognefest at its entrance is 50 m. by water from Bergen, in 61° 5′ N. For the first 50 m. the flanking mountains are unbroken by any considerable branch, but beyond this point several deep, narrow inlets penetrate the Jostedalsbrae and Jotunfjeld to the north, and the Hardangerfjeld to the south, being walled in at their heads by snow-clad mountains. The chief fjords are Fjaerlands, Sogndals and Lyster fjords to the north, Aardals fjord to the east, Laerdals and Aurlands fjords to the south. Branching from the last is the Naerö fjord, with a precipitous valley of great beauty (Naerödalen) at its head, and traversed by a road, from Gudvangen, across the Stalheim Pass to Vossevangen. Other villages are Vadheim, the terminus of the road from Nord fjord; Balholm and Fjaerlands (centres for visiting the glaciers of Jostedal); Lekinger, Sogndal and Laerdalsören, whence a road strikes south-east for the Valdres and Hallingdal districts.

SOIGNIES (or Soignes, the Walloon form), a busy and flourishing town of the province of Hainaut, owing its prosperity to the important limestone (Carboniferous) quarries in the neighbourhood. It contains a fine abbey church of the 12th century and in the cemetery connected with it are many tombstones of the 13th and 14th centuries. Pop. (1925) 10,676.

The forest of Soignies once extended over south Brabant up to the walls of Brussels and was part of the *Silva Carbonaria* of antiquity; even at the time of the French Revolution it was very extensive. Napoleon ordered 22,000 oaks to be cut down in it to build the Boulogne flotilla for the invasion of England. King William I. of the Netherlands continued the process because he thought it promoted prosperity. A considerable portion of the forest in the neighbourhood of Waterloo was assigned in 1815 to the duke of Wellington, and to the holder of the title as long as it endured. This portion of the forest was converted into farms only in the time of the second duke. The Bois de la Cambre (456 acres) on the outskirts of Brussels was formed out of the forest, and beyond it stretches the Forêt de Soignes, still so called.

SOIL. Soil is the surface layer of earth on which the land plants grow. It is derived from, and therefore is made of the same constituents as the rocks, but it has been subjected to the action of air and water which have altered and removed some of the original components so that the proportions of the various substances in the soil are not the same as in the parent rock. The mineral particles constitute the basis or foundation of the soil, but not the whole of it. In any region where rainfall and temperature conditions are favourable, vegetation rapidly springs up, obtaining its mineral nutrients and its nitrogen from the soil. The plants build up complex organic matter from the carbon dioxide of the air, using for this purpose the energy of sunlight, and when they die and their dead remains fall back on the soil there is introduced a new group of constituents: organic substances containing nitrogen, phosphorus, calcium, potassium, etc., and also stored up energy. These two components, the mineral substances derived from the rock, and the organic substances derived from previous generations of plants, constitute soil.

The obvious method of classifying soils would be to group them according to the rock from which they are derived. This method answers over restricted areas: it was used by Fallou in Central Germany and by Hall and Russell in their survey of Kent, Surrey and Sussex, but it is inapplicable over wide areas where the soil properties are much affected by the changes they have undergone during their formation. The first division, therefore, is:

1. Soils whose properties are determined mainly by the character of the parent rock, called by Glinka endodynamomorphic soils because internal factors have been the chief agents in making them.

2. Soils whose properties are determined mainly by external factors, rainfall, temperature, etc., called by Glinka ectodynamomorphic soils.

To the first division belong the soils of recent origin which have not yet had time to go through much of the decomposition they will still have to suffer: examples are furnished by many British soils which have been in existence only since the last glaciation. In the second group belong many of the continental soils which have been exposed to climatic agencies for long periods. These soils have been much studied by the Russians Dokuchaiev followed by Sibirtzev, Wysotski, Glinka, Neustruev and others who have shown that they are largely the product of climatic conditions: so much so, in fact, that the soil type can be predicted when the climatic type is known. They are subdivided by Glinka according to the amount and nature of the leaching they have suffered through the operation of climatic factors.

I. **Wet Conditions: Material Washed Down: Tendency to Acidity.**—1. *Efficient Leaching: Much Water and High Temperature. "Optimum Moisture Conditions." The Laterite Group.*—The organic matter rapidly oxidises, the carbonic acid dissolves out the sodium and potassium from the rock forming weak alkali carbonate solutions which dissolve out the silica formed by the hydrolysis of the silicates: finally so much of the silica and of the alkaline bases have gone that the residue consists chiefly of iron and aluminium oxides, the so-called sesquioxides. This group includes the laterites, found in the rainy region near the equator: possibly also the red soils of the Mediterranean region.

2. *Less Efficient Leaching: Less Water and Low Temperature. "Average Moisture Conditions." The Podsol Group.*—The organic matter does not decompose completely: alkali carbonate solutions are not formed: the silica formed by hydrolysis of silicates therefore does not wash out. Weak organic acids are, however, formed which dissolve out both the alkalis and the sesquioxides leaving a residue mainly of silica. This group includes the podsols, thoroughly leached acid forest soils: the grey clay soils of deciduous forests mainly oak (these contain some calcium carbonate) and the Brown earths of Ramann. Where the water cannot easily drain away the soil becomes waterlogged for longer or shorter intervals and the bog soils result. The material leached out is deposited not far below the surface where the conditions are somewhat different and usually form a compact layer or pan which is almost impervious to water.

II. **Between I. and III.**—*Still Less Leaching: Less Water but Higher Temperature: "Moderate Moisture Conditions" Steppe Soil Group.*—There are several sub-groups of these. (*a*) The black earths or Chernozens. Here there is good grass vegetation but very incomplete decomposition of the dead residues therefore much accumulation of humus which, however, being saturated with lime is not carried down as in the podsol group. The carbonic acid forms some alkaline carbonates as before and they wash down but the calcium carbonate does not get far before it is deposited. The calcium sulphate, however, washes farther down. These soils are neutral and fertile. (*b*) The chestnut coloured soils, formed in drier conditions where there is not much vegetation and little humus formation: in the cooler regions the surface layer contains humus and differs in colour from the layer below: in the warmer regions, however, the humus layer is either very thin or non-existent. Neither calcium carbonate nor calcium sulphate have washed down as in the preceding soils. There has been but little decomposition of the rock and consequently little or no transfer of bases or of silica from one level to another. Other sub-groups include grey soils and red soils of the desert steppes. These soils are neutral or alkaline.

III. **Dry Conditions:** *Soil Material Brought Up: Saline Soils with Tendency to Alkalinity.*—These soils occur only in arid regions: they are characterised by the presence of soluble salts in quantities that may be sufficient to interfere with vegetation. They fall into two groups: 1. those liable to occasional flooding: the "solonetz" group, 2. those not liable to flooding: the "solonchak." The former possess structure, the latter do not. In the solonetz group the sodium salts form a sodium clay which is less stable than the calcium clay and therefore lose iron and aluminium oxides which wash down leaving the surface layer richer in silica. Some of the humus is also carried down along cracks which, once formed, tend to be planes of weakness: the

soil therefore, on drying breaks into columns or irregular prisms. The solonchaks (no flooding) contain in their upper layers chlorides, sulphates and carbonates of calcium, magnesium and sodium: the group is subdivided according to the preponderance of the various cations: there is no washing down of humus, the different levels have somewhat similar textures, and there is no definite structure.

Finally there are the desert soils.

This method of classifying soils necessitates the study not only of the surface but also of the lower layers. The material dissolved out from the upper layer, or "A horizon," is washed down to the lower layer, or "B horizon," and is there and then precipitated more or less unchanged, or it interacts with other substances. Lower down the unaltered material, the "C horizon" is formed. The three horizons constitute the "profile" of the soil.

In a continental area where the character of the climate varies regularly in passing from one region to another the soils also vary regularly in the same way. The best illustration is in Russia itself: in the north are the frozen tundra: then farther south the podsols under forest: farther south still the grey soils all tending to be acid; then the black earths; then the chestnut coloured steppe soils all neutral, and finally in the dry arid regions come the alkali and the desert soils. Western Europe does not show so simple a zoning, but there still remains the relationship with the climate.

Agricultural and Ecological Groupings.—In many countries including the British Empire and America it is usual to study the soil in its relation to plant growth, and for this purpose a closer classification is necessary, the grouping being according to the texture and physical properties of the soils. The divisions are:—

I. *Mineral soils.* (1) sands, (2) loams, (3) clays.
II. *Calcareous soils.* Chalky soil.
III. *Organic soils.* (1) Peat: acid. (2) Fen or calcareous peat: neutral.

I. **Mineral Soils.**—The properties of the mineral soils are determined largely by the proportions of particles of different sizes. The grouping is only approximate, there being no rigid definitions or boundaries, and sandy soils shade off into loams, and loams into clays, through a continuous series where no sharp lines can be drawn. By international agreement among soil investigators it is now usual to divide the soil particles into groups of the following diameter sizes:

	English	German
Above 2 mm.	Stones	Kies
2·0–0·2 „	Coarse sand	Sand
0·2–0·02 „	Fine sand	Mo
0·02–0·002 mm.	Silt	Schluff, Staub
Below ·002 „	Clay	Schlamm, Ton

This grouping, like that of the soils, is in the main arbitrary, but it has ample justification, even though the actual figures for the limits could not be rigidly defended.

Sandy soils usually contain more than 60% of coarse and fine sand and less than 10 per cent of clay: loams contain 8 to 15 per cent of clay and more silt: clays contain still more clay—occasionally in England up to 40 per cent and not infrequently 20 per cent or more. The physical properties are discussed in detail later; the agricultural properties are:—*sandy soils:* easily permeable by air and water hence the plant roots are well aerated but may suffer from drought; these soils are easily cultivated and hence are much used for fruit, market garden and nursery work; *loams:* less easily permeable but sufficiently to allow ample aeration of roots and to prevent waterlogging: these are suitable for all types of crops; *clays:* much less permeable, liable to be waterlogged, sticky when wet, hard and difficult to cultivate when dry, and usually difficult for plant roots to penetrate. They are greatly improved by lime and by organic matter, usually in Great Britain they are left as grassland, cultivation being too costly, but they are well suited to wheat and beans.

These distinctions are closely connected with the chemical composition of the particles.

Coarse sand, fine sand, and probably also silt consist in the main of the unaltered mineral particles: complex silicates such as orthoclase, the ferrosilicates; and quartz; these can be identified by the mineralogical methods of Delage and Lagatu, van der Kolk, Steinriede and others. These are chemically almost inactive, and their composition plays only a subordinate part in determining their properties: the chief factor is their size, hence the grouping according to size.

Clay (*below ·002 mm.*) differs from sand and silt in two important respects (1) it is a colloid, (2) it differs from the original mineral and consists of much changed silicates, now regarded as compounds of insoluble complex alumino-silicic acids. The particles appear to consist of aggregates of much smaller particles, perhaps as little as 10 $\mu\mu$ in diameter, which however, are only with difficulty kept from joining up to form particles of 50 $\mu\mu$ or more. This fine material is isolated by means of the supercentrifuge and is called "Ultra clay"; it appears to be of the same general nature in all soils, the difference being in degree only; its physical properties are related to its chemical composition, varying approximately as the ratio $\frac{SiO_2}{Al_2O_3+Fe_2O_3}$ which varies in different samples between 1·2 and 3·2. As obtained by R. Bradfield from the prairie soils of Missouri the ultra clay contained 24·5% Al_2O_3; 45·5% SiO_2; 7% Fe_2O_3; 1·7% CaO; 1·4% MgO; 0·3% K_2O; it easily loses bases especially calcium. When these are gone it behaves like a weak acid showing all the usual titration phenomena with sharp end points. The equivalent weight of this "clay acid" is estimated by D. J. Hissink to be between 1,000 and 2,000, while Bradfield assigns it a dissociation constant of the order of 3^{-10}, the same as carbonic acid. The bases and their chemical interchanges have been much studied by Gedroiz in Russia and Hissink in Holland. They are readily displaced by dilute acids and other bases, hence they are called exchangeable bases: they consist mainly of calcium, magnesium, potassium and sodium. From the circumstance that the whole of the calcium of the clay can be so displaced, but only part of the others, it is inferred that the calcium is present entirely as exchangeable base while the others occur partly in some other form. Clay thus behaves like a complex acid and its interactions with soluble salts follow the ordinary stoichiometric laws and can be expressed by the usual type of equation:

$$\underbrace{\left[SiO_2, nAl_2O_3\right]\!\begin{cases}Ca\\H\\Mg, Na, K \text{ etc.}\end{cases}}_{\text{Solid phase}} \underbrace{+K+Cl}_{\text{Solution}} = \underbrace{\left[SiO_2, nAl_2O_3\right]K}_{\text{Solid phase}} \underbrace{+(Ca+Mg+H \text{ etc.})+Cl}_{\text{Solution}}$$

Among its basic radicals or cations there is usually hydrogen *i.e.*, the clay is not a saturated salt, hence in any interaction of this kind some acidity appears: it seems strange that an alumino-silicic acid should be able to displace so strong an acid as hydrochloric but the fact is easily demonstrated.

Little is known about the constitution of the acidic part beyond what is stated above. It is much larger than the ordinary acid molecule: the relative sizes are probably as a wheat grain is to a football, hence surface phenomena come much into play. The rapidity of exchange of cations when the clay is brought into a salt solution suggests that the clay cations are all on the surface, which would imply that the anions should be immediately below the surface of the ultimate particle, the same conception as the Helmholtz double electric layer, the inner being negative, and the outer positive. The flocculation produced by salts or acids under certain conditions accounts for some of the advantages of liming and it is discussed later.

The clay of normal fertile soils is mainly a calcium clay, calcium forming 80 per cent or more of the exchangeable bases: all present agricultural methods and varieties of crops have been developed for this. Two other clays occur fairly commonly in nature: acid or hydrogen clay, and sodium clay. Acid clay is formed in wet regions where, as the result of continual leaching with rain water containing always some carbonic acid, the calcium tends to be displaced by hydrogen: it differs in physical properties from calcium clay and is not amenable to the usual agricultural treatment used for calcium clay: it is less suited for plant growth

partly because of its acidity, partly because it competes with the plant for available bases. It is less stable than calcium clay, and tends to give up iron and aluminium oxides as its acidity increases. The best methods of dealing with acid clays are (1) to find crops tolerant of the conditions, *e.g.*, rye, oats, alsike, etc. and to breed more tolerant varieties: (2) to add sufficient calcium oxide or carbonate to reform the calcium clay. Sodium clay may form whenever sodium chloride comes in contact with soil: when the sea breaks in and floods the land, or, in arid regions, whenever drainage is not good and when the irrigation water contains sodium salts in solution, which it frequently does. As compared with calcium clay it is more easily deflocculated, it has more affinity for water, becomes more sticky and impervious when wet and much harder when dry. It is also less stable and tends to lose iron and aluminium oxides. Its worst property, so far as the plant is concerned, is that in presence of water it readily hydrolyzes and the sodium may combine with the CO_2 in the soil to form sodium carbonate, which not only intensifies its stickiness and imperviousness, but is toxic to plants. It can be reconverted to calcium clay by treatment with calcium sulphate and then flooding to wash out the sodium sulphate, but considerable improvement is effected by treatment with sulphur which oxidises to form sulphur acids and so reduces or neutralises alkalinity, a trouble that cannot be overcome by suitable cultivation.

Organic Matter.—The organic matter, as already stated, is derived from plants and therefore at the outset is composed of cellulose, lignin, protein, carbohydrates, waxes, oils and other plant constituents. In the soil it rapidly undergoes changes, being attacked by the vast population of micro-organisms which use it for food and energy supply. The general direction of the change, therefore, is a decomposition to simple compounds such as CO_2, water and ammonia, which is rapidly oxidised by specific micro-organisms first to nitrite then to nitrate. The reverse changes, however, go on. The micro-organisms during their growth build up their own tissue, which, in the aggregate forms an appreciable part of the soil organic matter. Some of the organisms, *e.g.*, the nitrifying organisms and the algae on the surface, assimilate CO_2 like plants, building it up in new organic matter; others, like *Clostridium* and *Azotobacter* may (though it is not known how far they actually do) assimilate gaseous nitrogen, converting it into protein; others again assimilate the decomposition products and reconvert them into complex organic substances, while still others such as the active amoebae, feed on members of the soil population. The net result is that the soil always contains the whole range of substances: the starting products mentioned alone: the simple end products CO_2, nitrate and inorganic compounds of phosphorus, sulphur, potassium, etc.; and a number of intermediate products in constant state of change. Among these the most characteristic are the black, sticky compounds collectively known as humus, which like clay, are colloidal, and therefore have great power of absorbing water and soluble substances but differ from clay in that they do not make the soil sticky but on the contrary render it more pliable. It is a complex mixture which has been resolved into the following groups:—

- Soluble in alkalis.
  - Soluble in water or dilute acids. Mulder's Apocrenic acid.
  - Precipitated by acids.
    - Soluble in water. Odén's Fulvic acid.
    - Soluble in alcohol. Hoppé-Seyler's and Oden's Hymatomelanic acid.
    - Insoluble in alcohol and organic solvents. Humic acid.
- Insoluble in alkalis, Humin*.

*Cold alkali.

Most investigators have confined their studies to humic acid although there is no evidence that it is any more important than the humin. Humic acid can be (and in the soil apparently is) formed in three different ways (1) from cellulose by micro-organisms (2) from lignin by chemical changes (3) from the mycelium of fungi: there are differences between all three, but all agree in general physical properties and also in their general effects in the soil. Humic acid from soil contains about 5% of nitrogen apparently as part of its molecule: it is therefore not entirely a cellulose or lignin condensation product. Oden regards it as a tetrabasic acid with an equivalent weight of about 300.

Calcium Carbonate and Calcium Phosphate.—These two substances are of vital importance to the plant. *Calcium carbonate* is derived from three sources (1) from the decomposition of plant residues *e.g.*, from calcium oxalate (2) from the weathering of rocks (3) from the calcareous deposits forming the chalk and limestone. As it slowly dissolves from the soil water it tends to wash out from the surface soil in humid and semi-arid regions and is either carried away in the drainage water, or if the rainfall be insufficient, is deposited lower down. Its valuable property in the soil is that it keeps the calcium clay stable, neutralises the humic acid, and maintains both in a flocculated physical state suitable for plant growth. *Calcium phosphate* is derived from fish and other marine animals, which are sometimes segregated as vast deposits many feet in thickness, as in North Africa and parts of the United States, sometimes disseminated through the mass of the formation as in the chalk. Some also occur as crystalline apatite. In the soil it is probably in the form of hydroxyapatite $(Ca_3P_2O_8)_3Ca(OH)_2$, but some of the phosphorus occurs in organic combination.

The Water or Soil Solution.—Soil usually contains some 8 to 15 per cent of its weight of water distributed over its particles and this contains some of all the soluble substances present: the amounts being much influenced by the changes effected with the clay and by the absorption by the colloids. In general it contains in agricultural soils about 0·05 to 0·2 per cent of total solid matter. It appears to contain all the chloride and nitrate present in the soil, along with the equivalent amount of calcium. It seems to be saturated with phosphate (about 1 to 3 parts per million of PO_4 being present whatever the moisture content of the soil). The concentration of potassium, however, increases as the moisture content of the soil decreases, but not proportionately like the chloride and the nitrate: this suggests an equilibrium between the potassium in the liquid and that in the solid phase. The chief constituents of the soil solution are calcium nitrate, bicarbonate and sulphate; its composition, however, varies with the growth of the crop, the season and the activity of the micro-organisms. Its agricultural and ecological significance is that it is the culture solution for the growth of plants. (E. J. R.)

THE PHYSICAL PROPERTIES OF SOIL

From the standpoint of physics the soil is regarded as a mass of particles of all shapes and sizes, between which are innumerable voids and interstices, serving as channels for the movement of water and air. The physical properties of this moist porous material are important, both in their bearing on problems of soil cultivation and in elucidating the environment of soil micro-organisms, on which soil fertility so largely depends.

A century ago, when scientific men first seriously turned their attention to agriculture, the physical properties of soil received much attention, and within the limits of existing knowledge, fairly satisfactory explanations were given of the broad differences in behaviour between light, or sandy, and heavy, or clayey soils. Sandy soils drained readily and were susceptible to drought, while clayey soils although resisting drought would lie wet, or even saturated, in rainy weather; the explanation offered was that the soil particles, and therefore the interstices, were largest in sandy soils and thus permitted easy drainage and quick drying out by evaporation of water into the atmosphere. The water was supposed to rise to the soil surface just as it does in a narrow glass capillary tube; hence the effect of a mulch of dry soil in conserving the moisture below it was attributed to the inability of the water to rise beyond the bottom of the mulched layer into the much wider voids in the mulch itself. This hypothesis, although adequate for a qualitative understanding of some of the broader features, offered no explanation of the supreme characteristic of

soil—the ability of individual particles to aggregate into crumbs or compound particles, that every gardener and farmer recognises as the essential feature of a good tilth. There was no obvious explanation to hand, and in any case, the brilliant achievements of Lawes and Gilbert with their promise of a complete chemical theory of soil fertility focused attention on soil chemistry to the exclusion of all other work. The subject was reopened by competent physicists in the closing years of last century. The underlying hypothesis was that the water was distributed over the surface of the soil particles in a continuous film, that was thinnest where the particles did not touch one another, and thickened into annular rings around the points of contact of particles. This distribution could be predicted, in fact, from the known laws of pure physics. This theory fitted reasonably well with the experimental facts. The slow movement of water from point to point within the soil, the existence of an optimum moisture content for plant growth, the inability of vegetation to extract the full moisture content from the soil, were phenomena that fell within this new theory, but the compound particle or soil crumb, still remained outside its scope. But the study of the colloidal state of matter that has been so actively pursued in recent years has opened a new field in soil science, for there are many suggestive analogies between the behaviour of collodial systems, and soil. Our present picture of the soil particle differs from the earlier form in that the particle surface is no longer regarded as inert, but as coated with colloidal material derived partly from inorganic weathering products of the soil and partly from the decayed organic residues of plants and micro-organisms. This mixed material has a complex composition, and some of the relationships between soil and its water content deduced from the earlier hypothesis are profoundly modified by its presence. This is especially true for moisture contents below saturation, *i.e.*, over the range of most importance to cultivation.

The Soil Material.—The practical man recognizes many different kinds of soil and grades them in a succession from heavy to light. The terms refer to the ease of cultivation; heavy soils are sticky when wet, require great skill in cultivation and may dry into hard clods, while light soils can be cultivated at almost any time. Various descriptive terms, such as clays, heavy, medium and light loams, and sandy soils mark the gradation from heavy to light types. When such soils are examined in the laboratory it is found, in general, that the greater the proportion of coarse or sandy particles present the lighter is the soil in the farmers' sense. A method, known as mechanical analysis, has been devised for sorting out the particles from a soil into groups of different average fineness, thus giving an impersonal and arithmetical specification in place of the purely qualitative terms, that naturally vary with the individual judgment. The method depends on the fact that the smaller the particle the slower will be its velocity of fall in water. If a mixture of soil and water is placed in a beaker, allowed to stand for a time, and the turbid suspension poured off, a sediment will be left in the bottom of the beaker. Water is added to the sediment, to the same height in the beaker as before, the whole is well mixed and allowed to stand for the same time before the fresh turbid suspension is poured off. Repetitions of this process will eventually clear the sediment of all particles whose effective diameter is less than a certain critical value that depends on the height of the liquid in the beaker and the time of settling. The collected turbid suspension can be similarly divided. In practice only some three or four divisions are made. These have already been given: those now in use in Great Britain are:

Name of fraction	Range of diameter
Clay	Less than 0·002 mm.
Silt	0·02 mm. to 0·002 mm.
Fine sand	0·2 ,, ,, 0·02 ,,
Coarse sand	2·0 ,, ,, 0·2 ,,

The sand fractions are separated by sieves, and the remaining two fractions by sedimentation in water as already described. Soils containing more than 25% by weight of the clay fraction are in the heavy class; the light soils contain at least 50–60% of coarse and fine sand. The silt fraction and the finer part of the fine sand fraction are exceedingly valuable constituents, and when present in amounts not exceeding 30%–40% produce the optimum moisture conditions: the soil drains easily and yet retains a good supply of moisture. The class of soils known as loams derive their desirable properties largely from this cause. If the silt fraction is present in greater amount than the clay a very difficult soil type is produced, that is less susceptible to ameliorative cultivation and manurial treatment than even heavy clay soils.

The colloidal character of the soil is associated mainly with the finest particles; the clay fraction therefore is of special interest. If a mechanical analysis of a heavy soil in good tilth were made without any preliminary treatment of the soil to break up the natural aggregates of particles, the clay fraction would be much less in amount than the true value, since each undisintegrated aggregate would behave as a single large particle. The examination of the best means of dispersing these aggregates into their constituent particles, which is essential for purposes of mechanical analysis, has thrown much light on the mechanism of compound particle formation. Calcium carbonate—a normal constituent of most soils—and organic matter both act as cementing agents and are removed by treatment with dilute acid and hydrogen peroxide respectively. Even when this is done the full percentage of the clay fraction is not obtained in the mechanical analysis unless a deflocculating agent such as ammonia is added to the water, when the finest clay particles remain in suspension indefinitely. The compound particle therefore may be regarded as a loose porous aggregate of single soil particles, held together partly by the mechanical cementing action of organic matter and calcium carbonate and partly by physico-chemical forces, analogous to those producing the phenomena of flocculation in many other colloidal materials. Part of the beneficial effect on soil fertility due to additions of chalk, or lime, and organic manures, is due to the improved tilth that results.

Soil Moisture.—The water requirements of vegetation are very considerable: for each unit of dry weight produced the plant transpires several hundred units of water, that must be taken up by the roots from the moisture in the soil. The moisture content of the soil represents the balance between supplies and withdrawals. Supplies are represented by rainfall (and irrigation where this is practiced) and by water raised by capillary action from the lower depths of the soil; the losses are due to evaporation at the soil surface, transpiration by vegetation, and downward percolation under the action of gravity. It is evident that the losses from causes other than transpiration must be reduced as much as possible if an adequate reserve of soil moisture is to be available for the plant. A soil in good tilth has the maximum water holding capacity; the compound particles act as sponges and provide a kind of water reservoir, while the comparatively large interstices between the adjacent aggregates permit of rapid drainage of excess water after periods of heavy rain. It was formerly thought that this percolation water could be brought back to the top soil by capillary action from a considerable depth, thus constituting a large reservoir of available moisture. Careful experiments show that this is not so. For distances greater than about 3 feet the return of water by capillary action is so slow as to be negligible. Hence the only moisture supply available for plants is that in the soil layers permeated by roots and a layer about three feet thick below this. A long series of records from the percolation gauges at Rothamsted shows that on the average about 50% of the total rainfall passes below the 5 foot depth, and this result emphasizes the necessity, even in a country of adequate and well distributed rainfall, for conserving by appropriate cultivations the soil moisture against direct loss by evaporation.

Soil Temperature.—In general any point on the earth's surface experiences a daily rise and fall, or a diurnal wave of temperature. The amplitude of this wave, or the difference between maximum and minimum temperature for the twenty-four hours progressively increases from winter to summer. When the soil surface is heated a difference of temperature is set up between it

and the subsoil and a heat wave is propagated downwards. The wave travels slowly and the amplitude decreases rapidly; it takes about four hours to reach the 6″ depth, while at 3 feet the daily fluctuations of temperature are inappreciable, only the seasonal change from winter to summer being observed. During the night period for the daily wave, and the autumn and winter for the annual wave the surface soil is cooling, and there is an outward flow of heat. Both daily and annual waves therefore have the character of an ebb and flow of heat.

The soil material even in the continuous or rock form is a poor conductor, and in the discrete particle form its conductivity is smaller still, since, apart from radiation and convection, heat can only pass from particle to particle through the points of contact. The presence of water as an annulus around these points of contact, improves the conductivity, although water itself has a low conductivity and high specific heat; the thermal contact is improved by the presence of the water film and the higher heat conductivity of the soil material is brought into play to an extent more than sufficient to compensate for the low conductivity of the water. Hence a soil that is in the optimum condition of moisture content is also in the best condition for heat conduction. Again, the existence on the surface of a dry mulch of soil, which has a very low conductivity, protects the soil below from extremes of heat and cold and preserves it at a steadier temperature, to the advantage of the vegetation. In general, the average soil temperature in the upper layers of soil in temperate regions varies from 20° C in the summer to 5° C in the winter.

Soil Air.—Analysis of the soil air shows that it differs but little from the composition of the ordinary atmosphere. The content of carbon dioxide is higher—about 2%–3% as against 0·03% and the oxygen content is correspondingly lower. Studies of biological activity in the soil show that about seven litres of carbon dioxide are produced daily for each square metre of soil surface, and the low content of this gas found by actual analysis of soil air, indicates that it readily escapes from the soil and is replaced by oxygen from the atmosphere. The mechanism of this exchange has been much disputed. Many workers have ascribed it to the pumping action of barometric, temperature and moisture changes in the soil causing expansion and contraction of the air in the interstices, and to the action of wind. Careful estimates of the effects of these actions show that they are insufficient to effect the exchange, which must therefore be due mainly to the phenomena of gaseous inter-diffusion. This process is continuous, whereas the other factors are intermittent.

DIAGRAMS SHOWING HABIT OF GROWTH OF CARROTS ON DIFFERENT TYPES OF SOIL

Although the normal soil atmosphere closely resembles the ordinary air there is evidence of a second atmosphere in the soil, that is composed very largely of carbon dioxide. It is sometimes referred to as the dissolved atmosphere, as it is slowly evolved after the normal soil atmosphere has been evacuated by suitable means in the laboratory. It appears to come from the moisture in the soil, and from the colloidal material, and it is probable that some of it comes from the excessively minute interstices in the interior of compound particles. The significance of the dissolved atmosphere is that it points to the possibility of anaerobic conditions existing at places even in a soil that is in excellent tilth, a point of considerable importance in connection with the environment of soil organisms.

Processes of Soil Cultivation.—Much of the significance of this section of soil physics has become apparent in the preceding sections. The aim of cultivation is to provide a suitable seed bed for active germination and vigorous early growth of the seedling plants, and to maintain the optimum conditions for subsequent plant growth. The basic operation is ploughing, and the tilth finally obtained is largely dependent on it. The heavier the soil the more important is proper ploughing. If the soil is too wet, the furrow slice suffers plastic deformation as it passes over the mouldboard, and as a result has a tendency to dry into large hard clods that resist the disintegrating action of the cultivators and harrows used in the next stages of seed bed preparation. When less moisture is present the furrow slice, although maintaining its general coherence, becomes permeated by numerous cracks on passing over the mouldboard, and subsequent disintegration of the soil by cultivators is much easier. Alternations of wet and dry spells are also of great service in assisting tilth formation, and the shattering effect of frost on heavy land is well known. As a general rule it may be stated that no cultivation process should be carried out unless the moisture content has fallen to a value that permits air to enter the soil interstices.

(B. A. K.)

BACTERIAL ACTIVITY IN THE SOIL

The organic material produced by green plants by means of photosynthesis provides a source of energy which maintains a dense population of micro-organisms in the soil. The bacteria, fungi and actinomycetes are of fundamental importance in the economy of the soil owing to their action in destroying dead plant remains and in producing those end-products of decomposition, such as nitrates upon which the new crop feeds. Two other necessary functions are performed by soil bacteria, the fixation of atmospheric nitrogen, which balances the washing out of nitrogen compounds from the soil by rain, and the solution of minerals such as potassium compounds and phosphates which are thus rendered available to the crop. Since the soil bacteria have usually been studied in relation to specific biochemical processes which take place, it is convenient to divide them into physiological groups according to the most important changes that they bring about. It must be remembered, however, that most soil organisms are not specific in their activity, but produce different chemical changes according to the nature of the available food supply.

The Decomposition of Plant Residues.—When plant remains are added to the soil the simpler sugars and starches are amongst the first components to be decomposed since they form a readily available source of energy to a great variety of micro-organisms. Pentosans, though not available to so many species are attacked by a number of bacteria and fungi. During the rotting of manure and in compost heaps pentosans play an important part in providing a supply of energy enabling bacteria and fungi to assimilate soluble ammonia and nitrate, thereby reducing the loss of valuable nitrogen. The bulk of dead plant remains consists of cellulose and lignocellulose. These substances, especially the latter, are much more resistant to decomposition and disappear more slowly than the simpler carbohydrates. The first cellulose decomposing organisms to be studied were anaerobic spore-forming rods which break down the cellulose into organic acids, CO_2, H_2 and methane. These organisms are of importance in such waterlogged soils as occur in paddy fields. The majority of agricultural soils, however, are well supplied with air, and the cellulose is attacked by aerobic organisms, a number of which have been isolated and studied. The most interesting of these is *Spirochoeta cytophaga,* an organism of remarkable appearance and doubtful systematic position. It possesses a life-cycle, the most typical stage being that of a flexible tapering filament staining with difficulty. This passes by intermediate stages into a spherical

deeply-staining body resembling a spore, though it is not resistent to heat nor is there evidence that it is a resting condition. In addition to this organism a considerable number of aerobic bacteria claimed to be cellulose decomposers, have been described. The most thoroughly investigated of these, *Microspira agar-liquifaciens* attacks filter paper rapidly and also possesses the unusual property of liquefying agar. Some actinomycetes and fungi are capable of attacking cellulose and it is likely that the latter are mainly operative in destroying the cellulose in acid soils where the environment is unsuited to the bacteria. The relative importance of bacteria, actinomycetes and fungi in this, as in other biochemical processes, is difficult to judge at present owing to the lack of an adequate technique for estimating the population of the latter two groups in soil. The cellulose in plant tissues is commonly combined or associated with lignin. The decomposition of lignin by bacteria, actinomycetes and fungi has been claimed to take place, but an exact study of its decomposition is hindered by the difficulty of obtaining this substance in a state of purity.

In addition to carbohydrates there are a number of other non-nitrogenous organic compounds released in the soil during the decomposition of plant remains. Amongst these are the aromatic compounds, such as phenol and indol, which are derived from proteins. A considerable number of bacteria that can decompose phenol, cresol and naphthalene occur in soil, while three organisms have been isolated which possess the power of oxidising indol into indigotin.

Bacteria and the Nitrogen Cycle.—The second great group of compounds left in the soil by plants and added thereto by manure are the nitrogen compounds such as proteins and their derivatives. Soil organisms themselves provide a further source of such compounds. The decomposition of organic nitrogen compounds can be brought about by a very large number of bacteria, actinomycetes and fungi and the great complexity of the soil microflora has rendered it impossible to isolate and classify more than a small fraction of these, or to follow the stages through by which proteins are decomposed. During the process, the nitrogen is released as ammonia. The production of ammonia is, however, a by-product in the economy of the bacteria, which are deriving energy by decomposing the organic compounds. They can indeed be prevented from attacking the proteins, if a more readily available non-nitrogenous energy source is offered them. Thus the production of ammonia in soil can be depressed by the addition of sugar or straw.

The ammonia that is produced in soil does not usually accumulate there, but is oxidised successively to nitrite and to nitrate. An interesting organism *Nitrosomonas* is able to oxidise ammonia to nitrite. Pure culture study has shown that this organism derives its carbon by synthesis from CO_2, a process which requires a considerable expenditure of energy. It is unable to utilise organic compounds as sources of carbon. The energy necessary for assimilation of CO_2, is obtained by oxidising ammonia to nitrite. The nitrifying organisms are normally very sensitive to acidity and will not work efficiently unless the nitrous acid that they produce is neutralised by an available base which in soil is usually calcium carbonate. Since however, nitrification will take place in certain acid forest soils, there are probably strains of the organism unusually tolerant of acid conditions. A second ammonia oxidising organism named *Nitrosococcus* has been described. It has been suggested that this is a stage in the life-history of *Nitrosomonas.*

The nitrites produced from ammonia do not accumulate in the soil but are rapidly oxidised to nitrates. An organism named *Nitrobacter,* capable of bringing this about, has been studied in pure culture. It resembles *Nitrosomonas* in deriving its carbon from CO_2 and obtains the necessary energy for this by oxidising nitrites. The activity of both *Nitrosomonas* and *Nitrobacter,* when grown in artificial media is hindered by the presence of soluble organic compounds. It is probable that in the soil they are less sensitive, since the formation of nitrate occurs rapidly in such media as richly manured soils and in the purification of sewage.

The nitrates produced in the soil are the principal source of nitrogen available to crop plants. They can also supply nitrogen to the majority of soil micro-organisms. When the soil contains an excess of available carbohydrate materials the energy supplied by these enables an immense multiplication of micro-organisms to take place and these obtain their nitrogen by assimilating nitrates and ammonium compounds, thus depleting the soil of nitrogen that would otherwise have been available to the crop plants. This is the principal reason why the ploughing in of straw and similar substances, in which the ratio of carbon to nitrogen is high, has a depressing action on the crop. The nitrogen locked up in the cells of micro-organisms is, of course, not lost to the soil, but is released by their death and decomposition, so that the loss of nitrates is only temporary. Indeed at times when the soil is uncropped, this assimilation of nitrates may be beneficial since it lessens the loss of nitrogen through the leaching action of rain. When the soil has become exhausted of its available nitrogen compounds, any further supply of carbohydrates can only be utilised by those micro-organisms that possess the power of taking up the free nitrogen in the soil atmosphere. A number of bacteria are now known that possess the power of assimilating or "fixing" elemental nitrogen. The first of these to be described was an anaerobic spore-forming rod, *Clostridium pasteurianum.* It has been shown that this organism increases rapidly in water-logged soil to which sugar is added, so that it may be of importance in wet soils. Recently, moreover, it has been found that *Clostridium* and various aerobic bacteria can grow in mixed culture in the presence of air, the aerobic bacteria presumably removing oxygen and creating an anaerobic environment for *Clostridium.* When sugar or mannitol is added to well aerated soil, however, aerobic nitrogen-fixing bacteria become predominant. Amongst these the most abundant is *Azotobacter.* The widespread distribution of *Azotobacter* and the fact that it is the chief form that appears when soluble carbohydrates are added to soil makes it probable that this organism is chiefly responsible for nitrogen fixation. It is very sensitive to acidity and does not develop in soils whose reaction is on the acid side of pH 6·0. It also requires a considerable supply of phosphates, a deficiency of which limits its development in certain soils. Various other aerobic nitrogen-fixing bacteria have been described but are probably of less importance in the soil than *Azotobacter.* The physiology of both *Azotobacter* and *Clostridium pasteurianum* have been much studied under laboratory conditions. The process by which nitrogen is fixed is not yet understood but it is probable that the nitrogen is combined with hydrogen and not with oxygen. It is claimed on thermodynamical grounds that this combination requires no expenditure of energy. In culture solutions, however, about 100 grams of dextrose are utilised by *Azotobacter* for every gram of nitrogen fixed, though the figure is very variable. No doubt the large amount of dextrose consumed also supplies the energy needed to build up protein from the simpler compounds that are first produced. *Clostridium pasteurianum,* with an anaerobic metabolism, consumes about 400 grams of dextrose per gram of nitrogen fixed. The difference between *Azotobacter* and *Clostridium* in this respect is due to the degree to which the carbohydrate is decomposed. *Azotobacter* breaks down the sugar almost completely to CO_2 and water, whereas with *Clostridium,* the decomposition is only partial, fatty acids, alcohol and H_2 being produced as well as CO_2. This partial decomposition produces far less energy per gram of sugar utilised than is obtained by *Azotobacter.* Indeed, the amount of nitrogen fixed per unit of energy made available, is higher in the case of the *Clostridium.* The efficiency of nitrogen fixation by *Azotobacter* is claimed to be higher in the soil than when it is grown in solution. Moreover, under natural conditions, it is probable that nitrogen fixing bacteria are assisted by the presence of other organisms which remove the by-products of their metabolism. Impure cultures have been found to fix more nitrogen than pure cultures, while the presence of protozoa has been found to stimulate fixation. The association of nitrogen fixing bacteria with green plants provides a special case of symbiosis. In this case the green plant, in addition to removing by-products, also supplies the bacteria with carbohydrate produced by photosynthesis. The association

of nitrogen-fixing bacteria with algae is a simple case. Of greater importance, however, is their association with higher plants, especially legumes. The organism forming nodules on the roots of legumes was first isolated in 1888 by Bejerinck who named it *Bacillus radicicola,* and since then has formed the subject of a great deal of research. The organism passes a portion of its life in the soil where it can exist for years without the presence of its host plant. It exists in several cell forms which appear to constitute a definite life-cycle.

At a certain stage in this life-cycle, small actively motile rounded cells are produced which are able to migrate rapidly through the soil. It is probably in this stage that it reaches the roots of the host legume. The bacteria enter the plant through the unicellular root-hairs. They attach themselves to the root hair near the tip and appear to soften the cell wall at the point of the entrance. Inside the hair they multiply and form a thread-like strand of mucilaginous material in which the bacteria are imbedded. This thread grows down the hair and passes inwards through the cortex of the root, actually penetrating the cells. As it progresses, the cells in its neighbourhood start to divide and the infecting thread of bacteria ramifies through the mass of dividing cells. The infected cells swell in size and the bacteria pass out of the infecting thread and come to lie in the cytoplasm of the host cells. At about this time vascular strands grow out into the cortex so as to surround the mass of infected cells. The presence of these strands is essential to nitrogen fixation within the nodule and it is probable that they are the avenues along which carbohydrates are brought to the bacteria and the products of nitrogen fixation are removed. The bacteria that form nodules on legumes are divisible into physiological varieties each of which can form nodules on only a small group, sometimes a single genus of legumes. These varieties can also be distinguished by serological tests. For many years attempts have been made to improve the growth of legumes by supplying the appropriate variety of the nodule organism either by spreading soil from a field where the said legume has been grown or by treating the seed with a suspension of the bacteria. When a legume has been introduced into a new district the soil of which does not naturally contain the specific variety of nodule organism, considerable benefit may result from such treatment. This is especially the case with lucerne (*Medicago sativa;* alfalfa) which has recently been introduced into new areas all over the world where it often will not make satisfactory growth unless supplied with the bacteria.

Bacterial Activity Under Anaerobic Soil Conditions.—The atmosphere existing in the pore spaces in the soil is usually similar to that of the overlying air though somewhat richer in CO_2. In normal cultivated soil the conditions are therefore suitable for the growth of aerobic bacteria. It is probable that, even in well aerated soil, conditions of deficient oxygen supply exist locally, for example in the centres of the masses of colloidal material. In waterlogged soils, moreover, the oxygen dissolved in the water is soon used up so that anaerobic conditions prevail. As mentioned above, such processes as cellulose decomposition and nitrogen fixation can be brought about by anaerobic organisms. Ammonia production from proteins also takes place rapidly under such conditions. Nitrate formation is, however, inhibited by a deficiency of free oxygen. Many anaerobes obtain their oxygen by reducing nitrates or nitrites and some by reducing sulphates, such reduction processes being therefore characteristic of waterlogged soils.

The Solution of Minerals.—The organic acids and CO_2 produced by bacteria in the soil have an important action in attacking insoluble phosphates and potassium salts and rendering these available to the crop. In the laboratory and probably in the field, rock phosphates can also be attacked by the acids produced by the nitrification of ammonium carbonate. There is also an interesting group of soil bacteria that can oxidise sulphur and sulphides producing sulphuric acid. The solubility of rock phosphates can be increased by composting with sulphur owing to the activity of such bacteria.

The Ecology of the Bacterial Population.—In keeping with the complexity of the biochemical changes that they bring about in soil is the enormous variety of morphological groups of micro-organisms that can be isolated from it. Indeed the number and variety of these has so far defeated efforts at systematic study and classification. The soil is continually liable to contamination from above and there is evidence that many of the bacteria that exist in the soil are not active inhabitants but are present in a resting condition. When a given source of energy is added to soil it usually causes an increase, not in the whole bacterial flora but in one or two specific types. It is thus probable that, in the future, soil bacteriologists will concentrate their attention on those types that multiply in the soil itself when given substances are added thereto. The study of the soil micro-organisms is further complicated by the fact that their numbers in a field soil are constantly fluctuating. These fluctuations take place not only from day to day but from hour to hour and their cause is not yet clearly understood, although they are related to similar fluctuations in the protozoan fauna. There is clearly a changing equilibrium between bacteria and active amoebae and probably between other groups of the soil population. In considering the effect of changes in the physico-chemical environment on the soil bacteria, the existence of this state of equilibrium has to be borne in mind. It is probably for this reason that changes in soil temperature and moisture can seldom be correlated directly with bacterial numbers. Extremes of temperature usually result in an increase in bacterial numbers probably because they are less harmful to the bacteria than to the protozoa which normally keep their numbers down. The reaction of the soil has been found to have a marked effect on soil bacteria, both the numbers and the quality of the flora being affected by it.

Certain groups such as the nitrifying bacteria and *Azotobacter* are very intolerant of acid conditions. The effect of alkali salts on soil bacteria has been studied on account of the importance of these salts in dry districts. There is evidence of antagonistic action between the various ions, two toxic salts being sometimes less harmful in combination than alone. Since potassium and phosphorus are essential constituents of protoplasm, it is found that potash salts and phosphates usually increase the numbers of bacteria in the soil. Lack of available phosphates are indeed a factor limiting bacterial growth in many soils, and this fact has been utilised as a test for phosphate requirement.

(H. G. T.)

SOIL PROTOZOA

Among the biologists of the nineteenth century it was recognized that protozoa could be isolated from soil, but it was not until the early part of the present century that the suggestion was made that such organisms might be taking a share in the general economy of the soil micro-population. The view that the presence of protozoa in large numbers may lead to "soil sickness" was first put forward by Russell and Hutchinson in 1909; and from that time the study of soil protozoology has been steadily pursued.

One of the first criticisms raised against the view that protozoa were of importance in the soil was that they were present only in small numbers and always in the cystic, that is quiescent state. That such an opinion was untenable was first demonstrated by Martin and Lewin who succeeded in isolating several species of flagellates and amoebae in an active condition from normal soils; and subsequent work, using more refined methods of technique, has proved the activity of these animals in many types of soil. In a recent survey by Sandon of soils obtained from all parts of the world no soil, even the most barren, was devoid of protozoa and in some cases the number of species was as great as forty-six. Altogether about 250 species have been recorded, a few of which occur only in soil; while the others being highly adaptable are also found in water rich in organic matter or similar habitats. All the species appear to be world-wide in their distribution, the same species occurring in arctic, temperate and tropical soils and up to the present it has not been possible to associate characteristic species with any particular geographical areas or soil types.

Protozoa are grouped into four main classes viz., the *Rhizopoda* or amoebae, the *Mastigophora* or flagellates, the *Ciliophora* or ciliates and *Sporozoa;* representatives of each of the first three

classes are found living in soil.

The life history of each species has its own characteristic features as regards nuclear division, etc., and in many forms, notably the amoebae, it is impossible to identify them with certainty unless the chief stages of the life history are known. In general, however, the soil protozoa pass through very similar phases and develop in a perfectly straightforward way. Broadly speaking, there are two main phases of the life history—a period of activity often mistermed vegetative, and a period of rest. In the former the animal moves, feeds and reproduces, while in the latter there is secreted round the body a thick wall, capable of resisting adverse external influences. This condition is termed the cystic stage, and by means of it the animals are distributed from place to place by air, water, etc. Indeed, so resistant are the cysts that many of them are capable of withstanding the action of the digestive juices of the intestines of animals, through which they pass to be deposited by the faeces on fresh ground.

Investigations into the activities of soil protozoa was at the beginning hampered by the absence of a method for enumerating their numbers. This difficulty has been overcome and it is now possible to make determinations of the size of the population in a sample of soil, and also to count both the numbers of cysts and active forms. Using this method in 1920 Cutler, Crump and Sandon made an extensive study of the bacterial and protozoal population of one of the field plots at Rothamsted. (Barnfield dunged plot.) Samples were taken every day for a year and the numbers of bacteria and of six species of protozoa counted. The numbers of all the organisms showed large fluctuations of two kinds, daily and seasonal, thus in the former case three consecutive samples gave 58·0, 14·25, and 36·25 millions of bacteria per gram respectively and the changes exhibited by any of the species of protozoa were equally marked. Such oscillations in the size of the population continued throughout the investigation and it is now known to be characteristic of all fertile soils.

The agent causing the bacterial fluctuations is mainly the active amoebae for during the year's count an inverse relationship was established between the active numbers of amoebae and the numbers of bacteria. Thus a rise from one day to the next in the amoebic population was correlated with a fall in the numbers of bacteria and vice versa. This conclusion has been substantiated by inoculation experiments in which sterile soil was inoculated in one case with bacteria alone and in the second case with the same bacteria together with amoebae. Since bacteria constitute the food of amoebae the above inverse relationship between the two groups is to be expected. Superimposed on the daily variations in numbers there are seasonal changes, in all the soil micro-organisms. In the spring and autumn the population rises to a maximum with corresponding falls in the summer and winter. It is interesting that these changes are very similar to those recorded for many aquatic organisms such as the algae and the plankton of the sea.

The action of protozoa on such soil reactions as ammonification, carbohydrate decomposition and carbon dioxide evolution has not been greatly tested; the small amount of evidence available, however, tends to the conclusion that in fertile soils amoebae act as inhibiting agents causing by their removal of bacteria a lessened production of ammonia from organic compounds and of carbon dioxide from carbohydrates. The fixation of atmospheric nitrogen by the bacterium *Azotobacter* is on the other hand increased when protozoa are associated with it although the protozoa use *Azotobacter* as their food supply. The probable explanation of the apparent anomaly is that the nitrogen in the bodies of the consumed bacteria is not lost, but conserved in the protozoan protoplasm; and also that the continued feeding action of the protozoa keeps the bacteria at a high rate of reproduction necessitating high metabolism with consequent increased nitrogen fixation.

Considerably more research is required along these lines, but the information so far obtained shows that the protozoa are important members of the soil population. (D. W. C.)

THE SOIL FUNGI

The serious study of the fungus flora of the soil commenced with the work of Oudemans and Köning a quarter of a century ago and since then our knowledge has shown a rapid growth associated chiefly with the names of Hagem and Traaen in Norway, Lendner in Switzerland, Münter in Germany, Dale and the Rothamsted workers in England, Jensen, Conn and Waksman in the United States of America and Takahashi in Japan. Compared with other soil organisms the fungi have been little studied but their primary importance is being increasingly recognized. For a time indeed there was doubt whether fungi lived vegetatively in the soil or were present merely as inert spores, but work at Rothamsted has shown that they may occur almost entirely in the active mycelial form.

In spite of the very great and in many cases, at present almost insuperable difficulties in the identification of soil fungi, a large number of kinds have been recorded including species of eleven genera of Phycomycetes, eight genera of Ascomycetes, and sixty two genera of Fungi Imperfecti. In addition Actinomycetes are present in great variety, Smut fungi occur and Hymenomycetes are present in very great abundance.

Investigations on the distribution of species of fungi in soil, although numerous, have presented no clear issues. In the work at Rothamsted no good evidence has been obtained of distinct fungal associations conditioned by soil factors. The numerical balance of different species varies considerably but no constant and clearly cut differences in kind have been found such as Hagem has reported for the Mucorineae of forest soils in Norway or as are so evident in the distribution of the larger fleshy forms of woods and meadows. Also the different species do not show any seasonal periodicity, the incidence of any particular form being apparently a matter of chance or determined by purely local conditions. Certain species however seem to penetrate the soil to greater depths than others, in the Rothamsted work species of *Penicillium, Fusarium, Saccharomyces, Zygorrhynchus* and *Trichoderma* always being found at the greatest depths.

Owing to the enormous differences in structure and reproduction of various soil fungi such as seen for example in species of *Saccharomyces, Mucor, Sordaria, Tuber, Coprinus, Phoma, Actinomyces,* it is not possible to obtain an estimate of the number of "individuals" per gram of soil that may be compared with protozoal or bacterial numbers. Yet by critical standardisation of technique, quantitative research is possible and results may be obtained that can be replicated and that do give information as to relative amounts of fungi in different soil samples. At Rothamsted, numbers exceeding "one million fungi" per gram of soil have often been obtained and these represent a fraction only of the fungi present. Different soils vary considerably in their numerical fungal content, the more fertile soils containing the greater numbers. Most of the fungi are in the superficial layers, the numbers fall rapidly in all cases below the 6–10 inch depth, and at greater depths than about three feet fungi are practically absent. Beyond a suggestion of lower numbers in winter and higher numbers in summer there is no good evidence of seasonal periodicity.

In the course of their metabolic activities fungi play an active part in the soil economy and, under aerobic conditions such as occur in most soils, they are probably the most important factor in the decomposition of the cellulosic matter of plant residues. At Rothamsted it has been found that under experimental conditions three thermophilic soil fungi, *Coprinus* (*fimetarius?*), *Aspergillus* (*fumigatus?*) and *Acremoniella* (*velutina?*) can, jointly, rot down cellulosic matter to a manurial condition (the "Adco process") as rapidly as the whole soil population and far more rapidly than a synthesized bacterial flora of the soil. A great deal of the plant residues decomposed by fungi is however utilised by them in the building up of their protoplasm which is an important part of the soil organic matter.

Fungi are active also in the decomposition of organic nitrogen compounds and the liberation of ammonia but, on the other hand, they assimilate available nitrogen compounds in the soil and so compete with crop plants. It has been suggested from time to time that soil fungi can fix atmospheric nitrogen but with the exception of *Phoma* sp. and possibly of *Orcheomyces* sp. this has yet to be proved.

An aspect of the soil fungi that is being increasingly recognised

as of fundamental importance is the mycorrhizal relationship of numerous forms with higher plants. The inner meaning of this symbiosis is not yet clear but there seems little doubt of its vital importance to the life of many host plants, both herbaceous forms and forest trees. On the other hand it is also being increasingly recognised that the soil is a reservoir of vast numbers of disease-causing fungi, some of the most destructive parasites of crop plants such as species of *Colletotrichum, Fusarium, Helminthosporium, Rhizoctonia, Phoma, Macrosporium* and *Alternaria, Botrytis, Thielavia, Sclerotinia, Phytophthora* and *Pythium, Cladosporium, Verticillium, Aphanomyces, Ozonium, Rhizopus, Cercospora, Rosellinia, Actinomyces* and numerous other genera being present in abundance. Certain other important parasites such as *Synchytrium endobioticum, Urophlyctis alfalfae*, etc., find their home in the soil although there is no evidence, as yet, that they carry on any vegetative existence apart from the host-plants. Certain slime moulds such as *Spongospora subterranea, Plasmodiophora brassicae, Cystospora batata, Molliardia triglochinis* and species of Ligniera occur in the soil and there is evidence that they may live vegetatively in this habitat.

The soil fungi are thus so diverse in their activities that it is quite impossible to assess their value in the profit and loss account of the agricultural ledger. The two outstanding facts are their vast importance and the comparatively slight attention they have received in soil science. (W. B. B.)

SOIL FERTILITY

The fertility of the soil is its power to support plant life, and the phrase has meaning because the general requirements of most cultivated plants in any particular region are very similar. A fertile soil has the following properties:—1. Sufficient depth to allow full root development. 2. Supplies sufficient moisture with unfailing regularity. 3. Supplies sufficient air for the roots. 4. Has suitable temperature. 5. Supplies adequate nutrients. 6. Has a suitable reaction. 7. Is free from any harmful factor. No soil is perfectly fertile, and the problem of the agriculturist is to discover the defects from studies of the soil and of the symptoms exhibited by the plant, and then to devise suitable remedies. Depth of soil is improved by deep cultivation, by removing a pan or layer of rock or by drainage to lower the water level. Water supply is improved: (1) by direct addition of water by irrigation, (2) by reducing loss of water: this can be done (a) by maintaining a fine layer of soil on the surface to act as a mulch to reduce evaporation: (b) in tropical countries by growing leafy crops to shade the earth from the sun's rays: (c) by incorporating organic matter (*e.g.*, farmyard manure) with the soil, thereby increasing the amount of colloid material and the power of absorbing water and preventing it from soaking through the soil. The folding of sheep on the land has the same effect and is one of the reasons why sheep are so valuable for the arable cultivation of light lands. Air supply is ensured by adequate cultivation, by drainage to remove excess of water and by the use of sufficient lime to keep the clay properly flocculated. Temperature is usually best improved by drainage: something can be done, however, by setting up the land in ridges and by dressings of soot. Nutrients are supplied in artificial manures, the use of which in proper amounts given at the most suitable time may greatly enhance yields. Many methods have been devised for analysing soil with a view of determining its probable fertiliser requirements: some are purely chemical and depend on the use of acid solvents, others, such as Neubauer's, use the seedling as the extracting agent: none is entirely successful though some in expert hands give useful information. The reaction is ascertained by determining the hydrogen ion concentration (pH value) of the soil, if this is neutral there is usually nothing to be done: if acid there are two methods of procedure: (1) the growth of crops (*e.g.*, rye, oats, alsike clover) specially suited to or tolerant of acidity, (2) the addition of lime or limestone to make the soil neutral. From the pH value alone it is not possible to estimate how much lime is required: several chemical methods have, however, been devised for this purpose. When the soil is alkaline the most suitable remedies are to add calcium sulphate or free sulphur, then to wash out the soluble salt taking care that the drainage is adequate. Harmful factors include (1) marked excess or deficiency of clay: in neither case is the soil usually cultivable; (2) excess of soluble salts: this is remedied by flooding with water and providing adequate drainage—an example is the reclamation of Lake Aboukir near Alexandria (3) in soils actually or recently waterlogged, sulphides, ferrous compounds and other reduction products: the remedy here is cultivation and aeration; (4) disease organisms and pests.

See D. K. Glinka, *Die Bodentypen;* E. J. Russell, *Soil Conditions and Plant Growth.* (E. J. R.)

Soil and Disease.—The influence of different kinds of soil as a factor in the production of disease has long been debated in regard not only to the nature and number of the micro-organisms they contain, but also to the amount of moisture and air in them and their capacity for heat. The moisture in soil is derived from the rain and the ground-water. Above the level of the ground-water the soil is kept moist by capillary attraction and by evaporation of the water below, by rainfall, and by movements of the ground-water; on the other hand, the upper layers are constantly losing moisture by evaporation from the surface and through vegetation. When the ground-water rises it forces air out of the soil; when it falls again it leaves the soil moist and full of air. The nature of the soil largely influences the amount of moisture it takes up or retains. In regard to water, all soils have two actions —namely, permeability and absorbability. Permeability is practically identical with the speed at which percolation takes place; through clay it is slow, but increases in rapidity through marls, loams, limestones, chalks, coarse gravels and fine sands, reaching a maximum in soil saturated with moisture. The amount of moisture retained depends mainly upon the absorbability of the soil, is greater for soils which consist of fine particles and increases with the amount of organic substances present. Above the level of the ground-water all soils contain air, varying in amount with the looseness of the soil. Some sands contain as much as 50% of air of nearly the same composition as atmospheric air. The oxygen, however, decreases with the depth, while the carbon dioxide increases.

Among the most noteworthy workers at the problems involved in the question of the influence of soil in the production of disease were von Foder, Pettenkofer, Levy, Fleck, von Naegeli, Schleesing, Muntz and Warrington. The study of epidemic and endemic diseases generally brought to light facts which were held strongly to suggest that an intimate association exists between the soil and the appearance and propagation of certain diseases; still the rôle played by the soil was not, and even yet, is not so well understood as to make it possible to separate the factors and dogmatize on their modes of action and possible effects. The general evidence indicated that the specific bacteria of cholera discharges, for example, are capable of a much longer existence in the superficial soil layers than was supposed; consequently it is necessary to guard against pollution of the soil, and through it against the probable contamination of both water and air. But it was the dampness of the soil and its temperature that were incriminated. The incidence of diphtheria and of typhoid fever, too, were regarded as associated with dampness of soil from consideration of the behaviour of B. diphtheria and of B. typhosus under appropriate experimental conditions. At the present time, the incidence is ascribed to the relative presence of carriers (*q.v.*) of the respective bacilli, and the influence of the soil becomes merged into the effect produced by soil and climatic factors on general health apart from the possibilities that they afford for leading to contamination of water supplies. The level of the ground-water and the liability of disease-producing bacteria in the soil, subjects to which great attention was given at the beginning of the century, hardly enter into modern discussions on the behaviour of epidemics.

SOISSONS, a city of France, capital of an arrondissement in the department of Aisne, 65 m. N.E. of Paris by the railway to Laon. Pop. (1926) 15,781.

Soissons is generally identified with the oppidum of Gallia Belgica, called *Noviodunum* by Caesar. Noviodunum was the

capital of the Suessiones, whose king, Divitiacus, had extended his authority beyond the sea among the Britons. In 58 B.C. Galba, king of the Suessiones, separated from the confederation of the Belgians and submitted to the Romans.

At the beginning of the empire Noviodunum took the name of *Augusta Suessionum,* and afterwards that of *Suessiona,* and became the second capital of Gallia Belgica, of which Reims was the metropolis. The town had walls and a citadel, and became the starting-point of military roads (to Reims, Château-Thierry, Meaux, Paris, Amiens and St. Quentin). Christianity was introduced by St. Crispin and St. Crispinian. In 297 their successor, St. Sinitius, became the first bishop of Soissons.

After the barbarians had crossed the Rhine and the Meuse Soissons became the metropolis of the Roman possessions in the north of Gaul, and on the defeat of Syagrius by Clovis the Franks seized the town. It was not till the time of Clotaire II., that the kingdom of Soissons was incorporated with that of Paris. Pippin the Short was at Soissons proclaimed king and was there crowned by St. Boniface, before being crowned at Saint Denis by the pope himself. In 923 Charles the Simple was defeated outside the walls by the supporters of Rudolph of Burgundy, and Hugh the Great besieged and partly burned the town in 948. The communal charter of the town dates from 1131. The town suffered severely during the Hundred Years War. It was sacked by Charles V. in 1544 and in 1565 by the Huguenots, who held the town for six months. During the League Soissons joined the Catholics. In 1814 Soissons was captured and recaptured by the allies and the French. In 1870 it capitulated to the Germans after a bombardment of three days. During the war of 1914–18 Soissons was for most of the time just behind the Franco-British lines but the Germans passed it in 1918 in their thrust for Paris (May 27); it was retaken in the Franco-British offensive of July 18, 1918.

In the middle ages Soissons was the chief town of a countship belonging in the 10th and 11th centuries to a family which apparently sprang from the counts of Vermandois. In 1625 the countship passed to the house of Thomas Francis of Savoy. In 1734 the male line of Savoy-Soissons became extinct and the countship was ceded to the house of Orleans who held it until 1780.

Soissons stands on the Aisne, the suburbs of St. Vaast and St. Médard lying on the right bank. The cathedral of Notre-Dame, partly ruined in the World War, was begun in the 12th century and finished by the end of the 13th.

There are still remains, though damaged, of the fine abbey of St. Jean-des-Vignes, where Thomas Beckett resided for a short time. These include the ruins of two cloisters (13th century) and the façade of the church, with three portals (13th century); the two unequal towers (230 and 246 ft.) of the 15th and early 16th centuries are surmounted by stone spires. The 13th century church of St. Léger, also damaged, formerly belonged to an abbey of the Génovéfains. Beneath are two Romanesque crypts. Before the war a barrack occupied the royal abbey of Notre-Dame, founded in 660 for monks and nuns by Leutrade, wife of Ebroïn, the celebrated mayor of the palace. The number of the nuns (216 in 858), the wealth of the library in manuscripts, the valuable relics, the high birth of the abbesses, the popularity of the pilgrimages, all contributed to the importance of this abbey. The wealthiest of all the abbeys in Soissons was that of St. Médard, founded about 560 by Clotaire I., beside the villa of Syagrius, which had become the palace of the Frankish kings. It was there that Childeric III., the last Merovingian, was deposed and Pippin the Short was crowned by the papal legate, and there Louis the Pious was kept in captivity in 833. The abbots of St. Médard coined money, and in Abelard's time (12th century) were lords of 220 villages, farms and manors. In 1530 St. Médard was visited by 300,000 pilgrims. The religious wars ruined the abbey, although it was restored by the Benedictines in 1637. Little remains of the abbey buildings except for the 9th century crypt and the dungeons.

Soissons is the seat of a bishop and a sub-prefect, and has a tribunal of commerce. Among the industrial establishments are iron and copper foundries, and factories for the production of boilers, agricultural implements and other iron goods, rubber goods, glass and sugar. There is a large trade in grain for the provisioning of Paris.

SOISSONS-REIMS, BATTLE OF, MAY-JUNE 1918: see CHEMIN-DES-DAMES, BATTLE OF THE, 1918.

SOKE, a word which at the time of the Norman Conquest generally denoted jurisdiction, but was often used vaguely and is probably incapable of precise definition. In some cases it denoted the right to hold a court, and in others only the right to receive the fines and forfeitures of the men over whom it was granted when they had been condemned in a court of competent jurisdiction.

In some versions of the much used tract *Interpretationes uocabulorum* soke is defined "aver fraunc court," and in others as "interpellacio maioris audientiae," which is glossed somewhat ambiguously as "claim a justis et requeste." Soke is also frequently associated to "sak" or "sake" in the alliterative jingle "sake and soke," but the two words are not etymologically related. The term "soke," unlike "sake," was sometimes used of the district over which the right of jurisdiction extended. (*See* SOCAGE.)

See A. Ballard, *The Domesday Inquest* (1906); F. W. Maitland, *Domesday Book and Beyond* (1907); J. H. Round, *Feudal England* (1909); F. H. Baring, *Domesday Tables* (1909); *Red Book of the Exchequer* (Rolls Series), iii. 1035.

SOKOL-DOBROPOLJE, BATTLE OF, 1918. This is the name usually given to the final offensive of the French, British and Serbian forces in Salonika, launched Sept. 15, 1918. Penetrating the enemy front, it split the Bulgarian forces and, followed up with great rapidity, was soon followed by the capitulation of Bulgaria, the first of the Germanic allies to yield in the World War (*q.v.*). *See* SALONIKA CAMPAIGNS.

SOKOLNIKOV, GREGORY YAKOVLEVICH (1888–), Russian communist, was the son of a doctor. He studied in Moscow and at Paris. From 1909 until the Revolution of Feb. 1917 he lived abroad. After the November Revolution, Sokolnikov at first worked in the Soviet finance department. At the end of 1921, immediately after the proclamation of the new economic policy, Sokolnikov was appointed to the committee of the people's commissariat of finance; at the beginning of 1922 he was deputy people's commissar and commissar soon after. In four years (1922–25) the system of taxes was restored, and the budget was put in order. The reform of the currency was begun at the end of 1922, and the new State bank was given the right of issuing notes; it was completed in 1924 with the reorganization of the treasury bills and the stabilization of the Soviet currency. At the end of 1925, when dissensions arose in the Communist party on the economic-political question, Sokolnikov criticised the Government policy. After the 14th congress of the Communist party in Jan. 1926 he was removed from the post of commissar of finance and appointed deputy president of the "Gosplan," or state-planning commission. In 1929 after the resumption of Soviet relations with Great Britain he became Soviet Ambassador to Great Britain.

SOKOTO, a province of the British protectorate of Nigeria, West Africa; formerly an independent state. The province occupies the north-west corner of the protectorate, and is bounded west and north by French territory; area 38,860 sq.m. Pop. (1926) 1,666,821. The southern part is fertile, with orchard bush. The northern part is more open and sandy merging into semi-Saharan conditions towards the frontier. Running through the province in a south-westerly direction is the Gublin Kebbi or Sokoto river, which rises in high land—the Niger-Chad divide—along the eastern border of the province. The Sokoto river joins the Niger in 11½° N. 4° E. The Niger itself flows through the south-west corner of the province. The capital, also called Sokoto, is in the northern part of the province, on a tributary of the Sokoto river. The province is pastoral and agricultural. The people have large herds of cattle and the trade in hides and skins is important. Horses are numerous. Of food crops guinea corn, millet and rice are extensively grown. Crops for export are groundnuts, produced in large quantities, and cotton. The cultivation of cotton since the World War increased very greatly. In 1928 the province was put in railway communication with Lagos, by the opening of

a line 107 miles long (specially built to serve a cotton area) from Zaria to Gasau. This line was extended in 1929 a further 30 m. to Kawra, a large town some 100 m. south-south-west of Sokoto.

History.—The Sokoto or Fula empire was founded at the beginning of the 19th century. The country over which the Fula ruled has, however, a history going back to the middle ages. Between the Niger and Bornu (*q.v.*) the country was inhabited by various negro tribes, of whom the Hausa occupied the plains. Under the influence of Berber and Arab tribes, who embraced Mohammedanism, the Hausa advanced in civilization, founded large cities, and developed a considerable trade, not only with the neighbouring countries, but, via the Sahara, with the Barbary states. The kingdoms which grew up round each large town had their own rulers, who from time to time fell under the sway of foreign powers. In the 17th century a dynasty of the Habe, a name now believed to be identical with Hausa, obtained power over a large area of what is now Northern Nigeria. The Hausa, whose conversion to Islam began in the 12th century, were still in the 18th century partly pagans, though their rulers were Mohammedans. These rulers built up an elaborate system of government which left a considerable share in the management of affairs to the body of the people.

Fula Empire Founded.—Dwelling among the Hausa were a number of Fula, mostly herdsmen, and these were devout Mohammedans. One of the more cultivated teachers of this race, named Othman Dan Fodio, had been tutor to the king of Gobir (a district north of Sokoto). He incurred the wrath of that king, who ordered the massacre of every Fula in his dominions. The Fula flocked to Fodio's aid, and in the battle of Koto or Rugga Fakko (1804) the king of Gibir was utterly defeated. Thereupon Fodio unfurled the green banner of Mohammed and preached a *jihad* or religious war. In a few years the Fula had subdued most of the Hausa states, some, like Kano, yielding easily in order to preserve their trade, others, like Katsina, offering a stubborn resistance. Gobir and Kebbi (a small state south of Gibir) remained unconquered, as did the pagan hill tribes. The Fula were also defeated in their attack on Bornu. In most places they continued the system of government which had grown up under the Habe, the chiefs or emirs of the various states being, however, tributary to Dan Fodio. That prince established himself at Sokoto and he and his successors are entitled sultans of Sokoto. Each also is known as *Sarikin Muslimin* (Commander of the Mohammedans) as indicating his spiritual authority. In the time of Sultan Bello, Dan Fodio's son, Europeans found their way to Sokoto and were well treated by that monarch. Thereafter intercourse with Europeans and Americans by way of the lower Niger grew. But Fula rule degenerated, and slave-raiding was on such a scale as to devastate and almost depopulate large areas, not only in Sokoto proper but in the neighbouring emirate of Gwandu (Gando).

Submission to the British.—In 1885, during "the scramble for Africa," the then sultan of Sokoto concluded a treaty with the company afterwards known as the Royal Niger Company, giving it certain rights of sovereignty throughout his dominions. These rights were transferred in 1900 to the British Crown, but it was not until 1903, after what is known as the Kano campaign (*see* NIGERIA), that British authority was established. The city of Sokoto made formal submission in March 1903; the sultan fled and was the next year killed in battle. The Fula chose a new sultan, who took the oath of allegiance to the British and retained many of the old rights of the sultans. After the establishment of British rule farmers and herdsmen reoccupied districts and the inhabitants of cities flocked back to the land, rebuilding villages which had been deserted for fifty years.

The emir of Gwandu, treated on the same terms as the emirs of Kano and Sokoto, proved less loyal and had to be deposed, another emir being installed in his place. In 1906 a rising attributed to religious fanaticism occurred near Sokoto, the leader of the insurgents claiming to be a Mahdi inspired to drive the white man out of the country. A British force marched against the rebels, who were overthrown with great loss in March, 1906. The leader was condemned to death in the sultan's court and executed in the market place of Sokoto. The incident was noteworthy for the display of loyalty to the British administration which it evoked from the native rulers after so short an experience of its working. For his loyal action the sultan was made a C.M.G. This sultan, Attahari, showed himself to be a progressive ruler. He died in 1915 and his successor, Mohammed Maiturare, who was, in 1921, also made a C.M.G., continued his policy. A rising of the Taureg in the neighbouring French territory in 1916 had no effect in Sokoto save to show the loyalty of sultan and people to the British. Under the advice of the British resident the native government proved increasingly efficient. Finance, education and public works were departments in which much activity was displayed.

SOKOTRA (also spelt Socotra and formerly Socotora), an island under British protection in the Indian ocean. It is cut by 12° 30′ N., 54° E., lies about 130 m. from Cape Guardafui, and is on the direct route to India by the Suez canal. It is 72 m. long by 22 m. broad and is the largest and most easterly member of a group of islands rising from adjacent coral banks, the others being Abd-el-Kuri, The Brothers (Semha and Darzi), and Kal Farun.

The centre of the island is formed of Archaean gneisses and granites with slightly younger schists. These form the highest peaks (the Haggier mountains 4,686 ft.). Resting on these rocks are Cretaceous and Eocene strata (chiefly limestone), which, scarcely disturbed, form an undulating plateau between 1,000 and 1,500 ft. above sea level. Some of these limestones are pierced by dykes and in the south-east by a small volcanic centre with trachytic and rhyolitic lavas. At many parts of the north coast the edges of the plateau reach the shore in precipitous cliffs, but in others wide alluvial plains, dotted with bushes and date-palms, front the heights behind. There are no harbours but several fairly safe anchorages.

From October to May the weather is almost rainless except in the mountains, where there are nightly showers and heavy mists. During this season the rivers, which are roaring torrents throughout the monsoon, are almost all lost in the dry, absorbent plains. The daily range of temperature of the coast area is from 65° to 85°, it may reach 95°; and on the mountains (3,500 ft.), from 52° to 72°. In the low grounds fever of an acute and hematuric form is very prevalent. The fauna contains no indigenous mammals; there is a wild ass, probably of Nubian origin; while the domestic cattle may be a race developed from cattle imported from Sind or Farther India. Of the flora aloes, dragon's-blood (*Dracaena*), myrrh, frankincense, pomegranate, and cucumber (*Dendrocycios*) trees are its most famous species. The flora and also the fauna present not only Asian and central African affinities, but, what is more interesting, Mascarene, South African and Antipodean-American relationships, indicating that the island represents part of Gondwanaland.

The inhabitants, about 12,000, are composed of two, if not more, elements. On the coast the people are modern Arabs mixed with negro, Indian and European blood; in the mountains live the true Sokotri, supposed to be originally immigrants from Arabia. Some of them are as light-skinned as Europeans, tall, robust, thin-lipped, straight-nosed, with straight black hair; others are shorter and darker, with round heads, long noses, thick lips, and scraggy limbs, indicating perhaps the commingling of more than one Semitic people. Their manner of life is simple in the extreme. Their dwellings are circular, rubble-built, flat, clay-topped houses, or caves in the limestone rocks. They speak a language allied to the Mahra of the opposite coast of Arabia. Both Mahra and Sokotri are probably daughter-tongues of the old Sabaean and Minaean. Sokotri is the older of the two languages, and retains the ancient form, which in the Mahran has been modified by Arabic and other influences. Hadibu (Tamarida), Kallansayia (Gollonsir), and Khadup are the only places of importance in the island. Hadibu (pop. about 400) the capital, is picturesquely

situated on the north coast at the head of the open bay of Tamarida on a semicircular plain enclosed by spurs of the Haggier mountains. A dense grove of date palms surrounds the village.

The chief export is ghi or clarified butter, which is sent to Arabia, Bombay and Zanzibar. Millet, cotton and tobacco are grown in small quantities. The most valuable vegetable products are aloes and the dragon's-blood tree. The Sokotran aloe is highly esteemed. The people live mainly on dates and milk.

Abd-el-Kuri island lies between Sokotra and Cape Guardafui, 60 m. from Sokotra and is 20 m. long by $3\frac{1}{2}$ m. in width. At either end the island is hilly. It is formed chiefly of Archaean rocks and on the north side is a sandy beach; on the south cliffs rise abruptly from the ocean. The highest part (1,670 ft.) is towards its eastern end. It is largely arid and there are no permanent streams. Its zoology resembles that of Sokotra, but the fauna includes land shells and scorpions peculiar to Abd-el-Kuri. The inhabitants (less than 200), speak Sokotri and Arabic and are chiefly engaged in diving for pearl shell on the Bacchus bank. They live chiefly on turtle (which abounds in the island), fish and molluscs. The land is nowhere cultivated.

Kal Farun is the name of two rocky islets rising nearly 300 ft. above the sea 13 m. from the western end of Abd-el-Kuri. Birds flock to them in great numbers; in consequence they are completely covered with guano, which gives them a snow-white appearance. The Brothers lie between Abd-el-Kuri and Sokotra. Semha is $6\frac{1}{2}$ m. long and 3 m. broad. It has rocky shores and rises in a table-shaped mountain to 2,440 ft. As in Abd-el-Kuri ambergris is found on its shores and turtles abound. There is running water all the year and it is a fishing ground of the Sokotri. Darzi lies 9 m. E. of Semha, is $3\frac{1}{2}$ m. long by 1 m. broad and rises almost perpendicularly from the sea to 1,500 feet. The coral banks which surround Sokotra and The Brothers are united and are not more than 30 fathoms below sea-level; a valley some 100 fathoms deep divides them from the bank around Abd-el-Kuri, while between Abd-el-Kuri and Cape Guardafui are depths of over 500 fathoms.

Lucas, *Historical Geography of the British Colonies* (1906).

HISTORY

Sokotra has claims to be reckoned one of the most ancient incense-supplying countries, and it is probably referred to by the Egyptians under the name "Terraces of Incense" (from its step-like contours).

To the Greeks and Romans Sokotra was known as the isle of Dioscorides; this name, and that by which the island is now known, are usually traced back to a Sanskrit form, Dvīpa-Sakhādhāra, "the island abode of bliss." The *Periplus* of the Erythraean Sea speaks of the island as peopled only in one part by a mixed race of Arab, Indian and Greek traders. It was subject to the king of the Incense Country, and was a meeting-place of Arabian and Indian ships. Cosmas in the 6th century says that the people spoke Greek and were largely Christian, with a bishop sent from Persia. They appear to have remained Nestorian Christians, with a bishop under the metropolitan of Persia, through the middle ages, though there are indications pointing to a connection with the Jacobite church. As early as the 10th century Sokotra was a haunt of pirates; in the 13th century Abulfeda describes the inhabitants as "Nestorian Christians and pirates" but the island was rather a station of the Indian corsairs who harassed the Arab trade with the Far East. The population seems in the middle ages to have been much larger than it is now; Arabian writers estimate the fighting men at 10,000.

The Portuguese under Tristão da Cunha and Albuquerque seized Sokotra in 1507 in pursuance of the design to control all the trade routes between Europe and the East, but abandoned it in 1511. They found that Sokotra was held by Arabs from Fartak, but the "natives" (a different race) were Christians, though in sad need of conversion. As late as the middle of the 17th century the Carmelite P. Vincenzo found that the people still called themselves Christians, and had a strange mixture of Jewish, Christian and Pagan rites. The women were all called Maria. No trace of Christianity is now found in the island, all the inhabitants professing Islam.

On the withdrawal of the Portuguese the dependence of Sokotra on Arabia was resumed. In the 19th century Sokotra formed part of the dominions of the sultan of Kishin. The opening of the Suez Canal route to India led to the island being secured for Great Britain. From 1876 onward a small subsidy has been paid to the sultan of Kishin by the authorities at Aden; and in 1886 the sultan concluded a treaty formally placing Sokotra and its dependencies under the protection of Great Britain. Sokotra is regarded as a dependency of Aden, but native rule is maintained, the local governor or viceroy of the sultan of Kishin being a member of that chief's family, and also styled sultan.

SOL, the original monetary unit of Peru. It consisted of 25 grammes of silver, $\frac{9}{10}$ fine, and was therefore equivalent to the French silver 5-franc piece. It was divided into 100 centesimos. In 1897 the Peruvian currency was changed from the silver to the gold standard. The new monetary unit was the libra or pound, equivalent to the British sovereign, which henceforward was also legal tender in Peru. The sol was revalued, and became a subsidiary coin, ten soles being equal to one pound. The sol was divided into 10 dineros and alternatively into 100 centavos.

Notes are not issued directly by the Government, but certain banks are permitted to issue notes of £P.10, 5, 1 and of 5 soles. £P is the conventional sign for the Peruvian pound. Exchange on London is usually quoted at so much per cent. premium or discount. 5% premium means that the pound sterling is worth that much more than the Peruvian pound, *i.e.*, £P.105=£100 sterling, and 5% discount means the reverse.

Since the war, the Peruvian and English pounds have moved far apart. The actual exchange rates for the post-war period, to be interpreted as above, are given in the following table:—

End of		*End of*	
1919	$7\frac{1}{4}$% dis.	1924	$14\frac{1}{2}$% pm.
1920	$17\frac{1}{2}$% dis.	1925	$23\frac{3}{4}$% pm.
1921	17% pm.	1926	$34\frac{3}{4}$% pm.
1922	10% pm.	1927	$23\frac{1}{4}$% pm.
1923	7% pm.		

Compared with many other South American countries, Peru had long had a good financial record, and relations with Great Britain were both close and cordial. This stood Peru in good stead immediately after the war, and though, at the end of 1920, the Peruvian pound only stood in New York at \$4.31 against parity of \$4.866, the pound sterling was as low as \$3.64, so that, comparing the two pounds, £100 sterling only equalled £P.82.5. 1921 witnessed a complete reversal from a rate of $17\frac{1}{2}$% discount to one of 17% premium, now in favour of London. To some extent this reflected a loss of ground by Peru against the United States, but the main cause was an improvement of 15% in the dollar value of sterling from \$3.64 to \$4.20.

Until 1925, the exchange between the two pounds only moved within relatively narrow limits, but during 1925 and 1926, the Peruvian pound depreciated until the London rate was $34\frac{3}{4}$% premium. Bad weather conditions and poor crops affected exports in the former year, and the commercial and credit position was difficult. Exports were further restricted in 1926 by the heavy world fall in the price of cotton and sugar, which form two of Peru's staple crops. A fruitless effort was made to arrest the depreciation of the Peruvian pound by the formation of an exchange pool, and at the end of the year relief to the adverse trade balance was sought by means of a bill giving the Government temporary powers to raise the customs duties on imported luxury articles. The year 1927 witnessed a recovery. (N. E. C.)

SOLANACEAE, in botany, a family of dicotyledons belonging to the sub-class Sympetalae (or Gamopetalae) and to the series Polemoniales, containing 72 genera with about 1,750 species, widely distributed through the tropics, but passing into the temperate zones. The chief centre of the family lies in Central and

South America; 36 of the genera are endemic in this region. It is represented in Britain by three genera including four species: *Hyoscyamus niger* (henbane), *Solanum Dulcamara* (bittersweet) and *S. nigrum* and *Atropa Belladonna* (deadly nightshade).

It is represented in North America by about 40 species, the conspicuous genera being *Solanum* (nightshade, bittersweet, horse nettle), *Physalis* (ground cherry), and *Datura* (jimson weed).

FROM "MEDIZINAL PFLANZEN" (KOEHLER)

THORN-APPLE OR JIMSON-WEED (DATURA STRAMONIUM), A COARSE ANNUAL PLANT OF THE NIGHTSHADE FAMILY (SOLANACEAE), FOUND WIDELY IN RICH SOILS IN TEMPERATE AND TROPICAL REGIONS

Nicotiana (tobacco) is represented by two species, one extending from Colorado to Nevada and California, and the other a native of Oregon, but cultivated by the Indians eastward to the Missouri river. The plants are herbs, shrubs or small trees. *Solanum nigrum,* a common weed in waste places, is a low-growing annual herb; *S. Dulcamara* is an irregularly climbing herb perennial by means of a widely creeping rhizome; *Atropa Belladonna* is a large perennial herb. The genus *Solanum,* to which belong more than half the species in the family, contains plants of very various habits including besides herbs, shrubs and trees. The leaves are generally alternate, but in the flower-bearing parts of the stem are often in pairs, an arrangement which, like the extra-axillary position of the flowers or cymes, results from a congenital union of axes.

In *Atropa Belladonna* one of the branches at each node is undeveloped and there is a pair of unequal leaves; the smaller subtends the branch which has not developed, the larger has been carried up from the node below.

The hermaphrodite, generally regular, flowers have the parts in fives, five sepals, five petals, five stamens in alternating whorls, and two carpels, which are generally placed obliquely. The corolla is regular and rotate as in *Solanum nigrum,* or bell-shaped as in *Atropa,* or somewhat irregular as in *Hyoscyamus;* in the tribe Salpiglossideae, which forms a link with the closely allied family Scrophulariaceae (*q.v.*), it is zygomorphic, forming *e.g.,* as in *Schizanthus,* a two-lipped flower. The stamens are inserted on the corolla tube and alternate with its lobes; in zygomorphic flowers only two or four fertile stamens are present. The flowers are generally conspicuous and honey is secreted on the disk at the base of the ovary or at the bottom of the corolla tube between the stamens. The ovary is usually bilocular, but in *Capsicum* becomes unilocular above, while in some cases an in-growth of a secondary septum makes it 4-celled as in *Datura,* or irregularly 3- to 5-celled as in *Nicandra.* The anatropous ovules are generally numerous on swollen axile placentae. The style is simple and bears a bilobed or capitate stigma. The fruit is a many-seeded berry, as in *Solanum,* or capsule, as in *Datura,* where it splits lengthwise, and *Hyoscyamus,* where it opens by a transverse lid forming a pyxidium. The embryo is bent or straight and embedded in endosperm. The persistent calyx may serve to protect the fruit or aid in its distribution, as in the red bladdery structure enveloping the fruit of *Physalis.*

The family is divided into five tribes after Wettstein; the division is based on the greater or less curvature of the embryo, the number of ovary cells and the regular or zygomorphic character of the flower. The great majority of the genera belong to the tribe Solaneae, which is characterized by a two-celled ovary. *Lycium* is a genus of trees or shrubs, often thorny, with a juicy berry; *L. chinense* (*L. barbarum*) is a straggling climber often cultivated under the name of tea-plant. For *Atropa, see* NIGHTSHADE; for *Hyoscyamus, see* HENBANE. *Physalis,* with 50 species mostly in the warmer parts of North and South America, includes *P. alkekengi,* "winter cherry," and *P. peruviana,* "Cape gooseberry. *Capsicum* (*q.v.*) is widely cultivated for its fruit, which are the so-called chillies. *Lycopersicon esculentum* is the tomato (*q.v.*) and *L. pimpinellifolium* is the currant-tomato; both are native to western South America, as is also *Cyphomandra betacea,* the tree-tomato. For *Mandragora, see* MANDRAKE. To the tribe *Datureae,* characterized by a four-celled ovary, belongs *Datura; D. Stramonium* (thorn apple), sometimes found as an escape in Britain, is officinal. *D. Metel,* native to India, and *D. meteloides,* of the south-western United States, are large-flowered annuals, grown in gardens in warm-temperate countries, as are the tree-like shrubs, *D. sanguinea,* native to Peru; *D. suaveolens,* native to Brazil, and *D. arborea,* of the central Andes. *Nicotiana,* to which belong the tobacco plant (*N. tabacum*) and other cultivated species, and *Petunia,* are American genera belonging to the tribe Cestreae, in which the embryo is straight or only slightly bent, as it is also in the tribe Salpiglossideae; *Salpiglossis* and *Schizanthus* are known in cultivation.

Among other plants of the family grown for ornament are the pepino (*Solanum muricatum*), Jerusalem-cherry (*S. Pseudo-Capsicum*), scarlet eggplant (*S. integrifolium*), tomatillo (*Physalis ixocarpa*) and strawberry-tomato (*P. pubescens*).

Numerous plants of the family are narcotic-poisonous, especially species of *Solanum* (nightshade), *Atropa* (belladonna), *Hyoscyamus* (henbane) and *Datura* (stramonium).

SOLANUM, in botany, one of the largest genera of flowering plants. It belongs to the nightshade family (Solanaceae, *q.v.*) and comprises upwards of 1,200 species, chiefly herbs but including many shrubs. It includes important economic plants, as the potato and egg-plant (*qq.v.*). Two species are found in Great Britain (*see* NIGHTSHADE), and about 25 in N. America.

SOLARIO, ANDREA DA (*c.* 1460–*c.* 1520), Italian painter of the Milanese school, was probably born at Milan, and received his early training from his brother Christofano, a distinguished sculptor and architect, who was employed extensively on work at the cathedral, Milan, and at the Certosa di Pavia. In 1490 he accompanied his brother to Venice, where he seems to have been strongly influenced by Antonello da Messina, who was then active in the city. The fine portrait of a Venetian Senator (National Gallery, London) displays Antonello's plastic conception of form and was probably painted about 1492. The two brothers returned to Milan in 1493. The "Ecce Homo" at the Poldi Pezzoli, notable for its strong modelling, may have been painted soon after his arrival. Solario's earliest dated work is a "Holy Family and St. Jerome" (Brera, Milan), with a fine landscape background, executed for S. Pietro at Murano in 1495. The Leonardesque type of the Madonna proves that Andrea after his return from Venice became strongly influenced by the great Florentine artist who was then carrying everything before him. To this period of Andrea belong a small "Crucifixion" (1503, Louvre) and the portrait of Charles of Amboise (Louvre); the portrait of Longono (1505, National Gallery, London); "The Annunciation" (1506, Fitzwilliam museum, Cambridge); and the beautiful "Vierge au coussin vert" (Louvre), for which a sensitive drawing of the Virgin's head is in the Ambrosiana at Milan; and the "Head of the Baptist in a silver charger" (1507, Louvre). In 1507 Andrea went to France with letters of introduction to

the Cardinal of Amboise, and was employed for two years on frescoes in the chapel of his castle of Gaillon in Normandy (demolished during the French revolution). According to Morelli's suggestion Andrea may have visited Flanders before returning to his native country, and this may account for the Flemish character of his later work. The artist was back in Italy in 1515, the date of the "Flight into Egypt" (Poldi Pezzoli collection) with its harmonious and detailed landscape background. To this period belong the "Procession to Calvary" (Borghese Gallery, Rome); the portrait of the Chancellor Domenico Morone (Palazzo Scotti, Milan); and the "Woman playing a guitar" (Hertz collection, Rome). Andrea's last work was an altarpiece representing "The Assumption of the Virgin," left unfinished at his death and completed by Bernadino di Campi about 1576.

See G. Morelli, *Italian Masters in German Galleries* (1883); K. Badt, *Andrea Solario* (Leipzig, 1914). (I. A. R.)

SOLAR SYSTEM: *see* PLANET.

SOLDER, an alloy easily melted and used as a cement to unite two metallic surfaces. The derivation is through the French from Lat. *soldare,* to make firm.

The soft solders are mainly compounds of tin and lead, and vary widely in composition. Common tinner's solder is composed of equal parts of tin and lead, and melts at 370°; plumber's solder has 2 of lead to 1 of tin. Excess of lead in plumber's solder renders the solder difficult to work; excess of tin allows it to melt too easily. Pewterers add bismuth to render the solder more fusible, *e.g.,* lead 4, tin 3, bismuth 2; or lead 1, tin 2, bismuth 1. Unless these are cooled quickly the bismuth separates out. The hard solders are the spelter and the silver solders. Soft spelter solder is composed of equal parts of copper and zinc, melted and granulated and passed through a sieve. As some of the zinc volatilizes the ultimate proportions are not quite equal. The proportion of zinc is increased if the solder is required to be softer or more fusible. A valuable property of the zinc is that its volatilization indicates the fusing of the solder. Silver solder is used for jewellery and other fine metal work, and has the advantage of high fusing points. The hardest contains from 4 parts of silver to 1 of copper; the softest 2 of silver to 1 of brass. Borax is the flux used with silver solder as with spelter.

The specifications of the American Society for Testing Materials (1921) are of two classes, of which class *A* is made from new or virgin metal and class *B* has at least one-half virgin metal. For galvanized iron and zinc, only class *A* solders should be used. In general, that solder should be selected which has the least amount of tin required to give suitable flowing and adhesive qualities. The specified compositions are given in the following table as well as the temperature at which melting begins, and the temperature of complete liquation.

Melting Points of Solder Metal

Grade	Composition			Melting begins at	Liquation complete
	Tin	Lead	Antimony		
	Per cent.	Per cent.	Per cent.	Degrees Fahrenheit	Degrees Fahrenheit
Tin .	100·00	..	..	449·6	449·6
0A .	63·00	37·00	0·12	357·8	357·8
1A .	50·00	50·00	0·12	357·8	415·4
1B .	49·25	50·00	0·75	365·0	397·4
2A .	45·00	55·00	0·12	357·8	437·0
2B .	43·50	55·00	1·50	370·4	428·0
3A .	40·00	60·00	0·12	357·8	458·6
3B .	38·00	60·00	2·00	370·4	442·4
4A .	37·50	62·50	0·12	357·8	467·6
4B .	35·50	62·50	2·00	370·4	411·8
5A .	33·00	67·00	0·12	357·8	485·6
5B .	31·00	67·00	2·00	370·4	455·0
Lead .	..	100·00	..	620·6	620·6

The permissible variation in the tin is not over 1%. Copper should not exceed 0·08% in class *A,* or 0·15 in class *B* grades. Other impurities not to exceed 0·10%. Grades *1A, 1B, 2A, 2B, 3A* and *3B* practically conform with the similarly numbered specifications of the Society of Automotive Engineers (1922). In addition, S.A.E. specification *No. 4* (1922) is a solder with lead 75%, tin 25, antimony 2·00 max., copper 0·08 max. in the *A* grade; tin, 23%, antimony 2·00 max. and copper 0·15 max. in the *B* grade. This solder is for work that is to be coated with enamel and then baked, as it withstands higher temperatures than the others listed. The complete liquation points are 514·5° for grade *A* and 496·5° for grade *B.*

Brazing Solder, or brazing spelter, consists of 50% to 55% of zinc, the remainder being copper. This is cast into ingots and granulated under a drop hammer into grades known as "long grain," "short grain," "fine grain," etc. The Society of Automotive Engineers specification *No. 45* (1922) calls for copper 50–52%, lead 0·50 max., iron 0·10 max., zinc remainder. This starts to melt at 1,560° and is completely melted at 1,600°. The material to be brazed may be dipped in molten brazing solder, or the solder in powdered form mixed with boric acid as a flux may be melted on the material in a furnace or by a torch. The alloy mainly used as brazing metal consists of 80% copper and 20% zinc. Brazing solder and metal are used to unite brass, copper, iron and steel in strong joints. Silver solder is used by jewellers and for other fine metal work. The hardest consists of 4 parts silver to 1 of copper; the softest, 2 parts silver to 1 of copper.

Fluxes for soft solders consist of powdered rosin, hydrochloric acid "killed" by the addition of zinc scraps, and tallow—when used by plumbers; for brazing and with silver solder, powdered borax. Sal ammoniac is sometimes used in brazing copper. Fluxes used to prevent the oxidization of the metals are borax, cream of tartar, sal ammoniac, resin, chloride of zinc and hydrochloric acid. There are many soldering pastes and solutions on the market.

SOLE, the name of flat-fishes of the genus *Solea,* which have the eyes small, on the right side, the head rounded in front, and the mouth small, curved, with teeth in the jaws of the blind side only. Several species are known from the Indo-Pacific and the eastern Atlantic. The common sole of Europe ranges from the North sea to the Mediterranean; it is a valuable food fish, which attains a length of 2 feet. It often burrows, and feeds mainly at night, seeking worms and other small animals of the sand or mud by smell and touch. The American soles belong to another genus, *Achirus;* they are small and of no value.

SOLENT, THE, a strait of the English Channel, between the mainland (the coast of Hampshire, England), and the coast of the Isle of Wight. Its length from Southampton Water to the Needles is 15 m., and from Southampton Water to a line drawn from Bembridge Foreland to Southsea Castle is 12 m. The breadth is from 2½ to 4 m., but between Stone point and Egypt point it narrows to 1¼ m.; and 3½ m. north of the Needles there springs from the mainland a great shingle bank, nearly 2 m. in length, which reduces the breadth of the Solent to a little over ¾ m. Its eastern portion is on the whole wider than the western. Hurst castle, at the western end, dates from the time of Henry VIII. Here Charles I. was imprisoned in 1648. The low coast of the mainland is broken by the estuaries of the Beaulieu river and the Lym, with the port of Lymington upon it. The coast of Wight rises more steeply, and the Medina, Newton and Yar estuaries open on to it. At the mouth of Southampton Water is a projecting bar like that of Hurst castle, and like it bearing a Tudor fortress, Calshot castle. The Solent is frequently the scene of yacht races, and its eastern portion has unique naval importance. The configuration of the coast causes a double tide in the strait.

SOLESMES, a village of western France on the left bank of the Sarthe in the department of Sarthe, 29 m. W.S.W. of Le Mans by road. In 1010 a priory was founded at Solesmes and placed under the authority of the abbey of LaCouture of Le Mans. Suppressed at the revolution, it was established as a Benedictine monastery in 1830. In 1837 it was raised to the rank of abbey and a nunnery was afterwards founded beside it, but both institutions were abandoned in 1901. The monastery church possesses two masterpieces of early 16th century sculpture; one represents the burial of Christ, the other that of the Virgin.

SOLF, WILHELM (1862–), German colonial politician, was born on Oct. 5, 1862, in Berlin. After studying Sanskrit and oriental languages in Calcutta, he returned to Germany and

entered the German colonial service, being sent to Soma. Here he first held the post of president of the municipal council (1899) at Apia under the old "condominium" of Great Britain, Germany and America, and afterward that of governor of German Samoa (1900). In 1911 he was appointed German colonial secretary and effected considerable reforms in German colonial administration. When Prince Max of Baden's Ministry of desperation was formed towards the end of the World War, Solf was appointed secretary of state for foreign affairs on Oct. 3, 1918. In this capacity he conducted the negotiations for the Armistice. He resigned on Dec. 17, 1918. In 1920 he was appointed German chargé d'Affaires and afterwards ambassador to Tokyo.

He was the author of *Weltpolitik und Kolonialpolitik* (1918), and of *Kolonialpolitik, Mein politisches Vermächtniss* (1919).

SOLFATARA, a volcanic vent emitting vapours chiefly of sulphurous character (whence the name, from Ital. *solfo*, sulphur; the French geologists' term is *soufrière*). The typical example is the famous Solfatara, near Pozzuoli, in the Phlegraean Fields, west of Naples. This is an old crater which has not been in active eruption since A.D. 1198, but which is continuously exhaling heated vapours, chiefly hydrogen sulphide, sulphur dioxide and steam. Sal ammoniac occurs among the sublimates. The term solfatara has been extended to all dormant volcanoes of this type; and a volcano which has ceased to emit lava or ashes but still evolves heated vapours is said to have passed into the "solfataric stage." (*See* VOLCANO and FUMAROLE.)

SOLFERINO, 5 m. W. of the river Mincio, was the scene of a battle between the Franco-Sardinians, commanded by Napoleon III., and the Austrians under Francis Joseph. Defeated at Magenta, June 4, 1859, the Austrians under Gyulai retreated across the Mincio and reorganized their forces around Verona. Francis Joseph then assumed personal command, aided by Gen. Hess. His forces comprised two armies: I., Wimpffen; II., Schlick; 160,000 strong. Early on June 24, when neither army expected to encounter the other, the armies suddenly met at the Mincio, both having assumed the offensive. The Franco-Sardinians, 150,000 men, moved on a 25 m. front from Lake Garda to Castel Goffredo. Outpost firing began at 5.30 A.M., developing later into more serious fighting. At 7 A.M. Napoleon, who watched the encounter from the church tower at Castiglione, ordered his forces to advance on Solferino, situated on an elevation, seemingly strongly occupied. After desperate fighting it was captured by the French Guards, entailing the sacrifice of thousands of lives. This brought about a distinct tactical advantage to the French, the Austrians continuing to make further attempts to recapture this important point. Further south of Solferino, MacMahon captured Cassiano, but the Sardinians, under King Victor Emmanuel, vainly assaulted the Austrian lines south of Lake Garda, being thrown back on Revoltella by Benedek. At 2 P.M. Francis Joseph gave a fresh order to Wimpffen to advance resolutely and to thrust back the enemy south of Solferino, but all his attempts were abortive. About 4 P.M. the oppressive heat was succeeded by a severe thunderstorm, of which the Austrians took advantage to retreat, except Benedek's troops. They accomplished this unmolested, the French being too exhausted to pursue them. The Sardinians then again fell on Benedek, who, seeing the Austrian centre retreat, himself retired, keeping the enemy at a distance. The Austrians re-crossed the Mincio that evening, having lost 22,000 men, the Allies 17,000 troops. A meeting of the two emperors took place shortly afterwards at Villafranca, after which hostilities ceased.

SOLI (mod. *Mezetlü*), an ancient town of Asia Minor, on the coast of Cilicia. Colonists from Argos in Greece and Lindus in Rhodes are described as the founders of the town, which is first mentioned at the time of the expedition of the younger Cyrus. In the 4th century B.C. it was so wealthy that Alexander could exact a fine of 200 talents. In the Mithradatic War, Soli was destroyed by Tigranes, but it was subsequently rebuilt by Pompey, who settled there many of the pirates whom he had captured, and called the town Pompeiopolis. Soli was the birthplace of Chrysippus the Stoic and of the poets Philemon and Aratus. The bad Greek spoken there gave rise to the term σολοικισμός, solecism, which has found its way into all the modern languages of Europe. Little remains of the ruins.

SOLI (mod. *Soliais*), a Greek city on the north coast of Cyprus, in the metalliferous country round Karavostasi. Its territory was bounded by those of Marion, Paphos, Tamassus and Lapathus. It was believed to have been founded after the Trojan War (*c.* 1180) by the Attic hero Acamas; and no remains have been found earlier than this. Soli is probably the town "Sillu," whose king Irisu was an ally of Assur-bani-pal of Assyria in 668 B.C. In Hellenic times Soli had little political importance, though it stood a siege from the Persians soon after 500 B.C.; its copper mines, however, were famous, and a neighbouring monastery is dedicated to "Our Lady of the Slag-heaps" (*Panagia Skourgiótissa*). In recent years the old mines have been reopened, and the tailings exploited.

See W. H. Engel, *Kypros* (Berlin, 1841; classical authorities); J. L. Myres and M. Ohnefalsch-Richter, *Cyprus Museum Catalogue* (Oxford, 1899; antiquities); G. F. Hill, *Brit. Mus. Cat. Coins of Cyprus* (London, 1904; coins).

SOLICITOR, in England, an officer of the Supreme Court of Judicature qualified to conduct legal proceedings for his clients: *see* also ATTORNEY. It seems that until 1873 there was a distinction between the terms "solicitor" and "attorney." Solicitors appear to have been at first distinguished from attorneys as not having the attorney's power to bind their principals; subsequently the distinction was between attorneys as agents in actions at law, and solicitors in chancery. In practice, however, the terms were synonymous, for it was usual for attorneys to be admitted as solicitors also. The Judicature Act 1873 enacted that all persons admitted as solicitors, attorneys or proctors of an English court should thenceforth be called solicitors of the Supreme Court.

Every person, before he can become a duly qualified solicitor, must serve an apprenticeship or clerkship to a practising solicitor for a term of years varying from three to five. Since 1922 he has been required during one of those years to attend a law school provided or approved by the Law Society (long known as the Incorporated Law Society). Service under articles therefore combines academic training with practical experience. The clerk must pass all the necessary examinations, he must be duly admitted, and must take out an annual certificate to practise. The organization of the profession is in the hands of the Law Society. Established 1827, and succeeding a society dating back to 1739, it was incorporated in 1831. The Solicitors Act 1922 transferred to the Law Society disciplinary powers long exercised by the courts. Its Discipline Committee may, after inquiry, strike off the roll or suspend from practice solicitors convicted of crime or found guilty of professional misconduct. In conjunction with the provincial law societies it has taken over the organization of the voluntary services of solicitors in the conduct of poor persons' cases. Apart from its judicial and administrative authority the Law Society has frequently exercised powerful influence by the attitude which it has taken towards proposed legislation. Membership of the society, which is not compulsory, is open to any duly qualified practising solicitor.

No person can be admitted as a solicitor unless he is a British subject, and has attained the age of 21 years. Though admitted as a solicitor and his name entered on the roll, he is not at liberty to practise until he has taken out his annual certificate, the fee for which is larger for London than for country practitioners. The disqualification of women to become solicitors ceased in 1919.

Solicitors now have a right to practise in any court, *i.e.*, in every division of the High Court, in every inferior court, in the ecclesiastical courts (*see* PROCTORS), in the court of appeal, in the Privy Council and in the House of Lords. Their right of audience, however, is restricted. They may appear as advocates in most of the inferior courts, as before justices, magistrates, coroners, and county courts. They have no right of audience, however, in the High Court of Justice (except in certain bankruptcy matters), nor in the Privy Council or House of Lords, where, from time immemorial, the right has pertained to the bar; but they have right of audience in chambers.

Solicitors have for more than two centuries done all kinds of

conveyancing, which, at one time, was claimed to be the exculsive business of the bar and scriveners. The Conveyancing Act 1881 having made changes in the practice of conveyancing, the remuneration of solicitors was placed upon a new basis by an order which provided scales of fees based on the amount involved in the transaction, not, as was generally the case before, simply on the length of the documents perused or prepared.

All communications which pass between a solicitor and his client are privileged; so also is any information or document which he has obtained in his professional capacity on behalf of his client. The relation of solicitor and client disqualifies the former from dealing with his client on his own behalf, while it gives him a lien for his professional charges, over the deeds, etc., of the client in his possession. A solicitor's remuneration is minutely arranged by statute. He has no power of recovering more from his client than his statutory charges, and he is liable to be sued for damages for negligence in his client's behalf. Certain personal privileges belong to a solicitor. He is free from serving on juries, nor need he, against his will, serve as a mayor, sheriff, overseer or churchwarden.

In Scotland "law agent" is the general term devised by the legislature to embrace the various writers, solicitors and procurators entitled to practise as agents in the supreme and inferior courts. The Law Agents (Scotland) Act 1873 now regulates the admission of applicants to the roll of law agents entitled to practise in Scotland. The apprenticeship varies from three to five years and the applicant must also pass a general examination and an examination in law unless he is a university graduate. A law agent is removable from the roll upon a petition to the court of session. Separate rolls are kept of law agents entitled to practise (a) in the court of session and (b) in each of the sheriff courts. As in England, the law agent has a limited right of audience, *i.e.*, only in the bill chamber of the court of session and in the inferior courts. Many law agents are members of one or other of the incorporations of which the principal are His Majesty's writers to the signet, the solicitors in the supreme courts, the faculty of procurators in Glasgow, and the society of advocates in Aberdeen. In the United States the term solicitor is used in some States in the sense of a law agent practising before a court of equity.

Some of the great public offices in England and the United States have their solicitors. In England the Treasury solicitor fills an especially important position. He is responsible for the enforcement of payments due to the Treasury, and conducts generally its legal business and that of most Government departments. The office of king's proctor is combined with that of Treasury solicitor. The Treasury solicitor as nominee of the Crown acts as administrator of the personal estate of an intestate which has lapsed to the Crown, and as king's proctor intervenes in cases of divorce where collusion is alleged (*see* PROCTOR). In Ireland solicitors called Crown solicitors are attached to each circuit, their duty being to prepare the case for the Crown in all criminal prosecutions. In the United States the office of solicitor to the Treasury was created by Act of Congress in 1830. His principal duties were to take measures for protecting the revenue and to deal with lands acquired by the United States judicial process or vested in them by security for payment of debts.

See E. B. V. Christian, *A Short History of Solicitors* (1896); A. Cordrey, *The Law Relating to Solicitors* (1878); A. P. Poley, *Law Affecting Solicitors* (1897).

SOLICITOR-GENERAL, in England, one of the law officers of the Crown, first appointed by letters patent in 1461 as deputy of the attorney-general (*q.v.*), and so called because he was more concerned with matters in chancery. His duties are now practically the same as those of the attorney-general, to whom he is subordinate, and whose business and authority devolves upon him in case of a vacancy. The position of the solicitor-general for Scotland in the main corresponds with that of the English solicitor-general. He ranks next to the lord-advocate. In the United States the office of solicitor-general was created by Act of Congress in 1870.

SOLIDS, GEOMETRIC. The term solid is not widely used in geometry as a precise generic term, but it commonly appears in the names of certain special classes of geometric configurations. A geometric configuration is any set of points in space which, unless the contrary is stated, is understood to be the space of euclidean three-dimensional geometry. We may set down that any geometric configuration is a geometric solid, or simply a solid, if every point of the configuration is the centre of a sphere whose interior contains only points of the configuration, and if the configuration is not composed of two configurations which have no points in common and which are such that every point of each configuration is the centre of a sphere whose interior contains only points of that configuration. It will be seen readily that according to this definition the interior of a sphere is a solid, while the configuration consisting of that interior and the sphere, *i.e.*, the spherical surface, is not a solid. It is easy to modify the given definition so as to permit calling the latter configuration a solid. This requires making precise the idea of the boundary of a configuration. A *boundary point* of a configuration is a point such that every sphere having it as centre contains points of the configuration and also points which do not belong to the configuration. A boundary point of a configuration need not belong to the configuration. The set of all boundary points of a configuration is called the *boundary of the configuration.* We shall now define a solid as any configuration consisting of a solid according to the original definition and the boundary of the latter configuration, and shall refer to the latter configuration as the interior of the solid thus newly defined. There are simple solids such as those commonly referred to as the sphere, cube, pyramid, ellipsoid, cylinder and the less simple ones, such as the torus or anchor ring and a sphere with a number of holes bored through it, and so on to solids of great complexity; *e.g.*, the abstract analogue of natural objects, such as a sponge or the steel framework of a building. The task of making a complete detailed classification of solids is thus an enormous one. For certain restricted, though important, classes of solids the problem of classification has been solved to such an extent that the associated theory is an interesting and important chapter of mathematics. An example of such a class is the class of polyhedra, which is taken up in some detail below.

A useful procedure in attacking the general problem of classification is the study of the boundaries of solids. Although several solids may have the same boundary the ambiguity thus arising in the determination of a solid by its boundary is easily settled in the case of a great class of solids; viz., all those which have been studied in a systematic way. Thus a classification of the boundaries of solids determines a classification of solids. The boundaries of solids may be extremely complicated configurations, but in the case of the solids of the large class just referred to the boundaries have a speciality which is sufficient for a quite complete classification and theory. The solids referred to are those whose boundaries are closed surfaces. A sphere, a torus, a polyhedron are examples of closed surfaces, and a more complicated example of such a surface is the surface of the solid which results from boring any number (finite or infinite) of holes, properly located, through a sphere. A precise definition of the concept of closed surface will not be given now and an ordinary intuitive counterpart of that concept will serve provisionally.

In studying the properties of solids, it is helpful to divide those properties into metric and non-metric properties. A general property of the latter kind involves merely the way in which parts of the solid are attached to each other, *i.e.*, the connection of the solid; while a metric property refers to size and shape, thus involving a comparison with other solids in regard to such relations as congruence and similarity. A special kind of non-metric property, sometimes called descriptive, involves such notions as linearity, parallelism and convexity. The non-metrical properties are the more primitive and simple, but metrical relations (such as congruence) are also fundamental.

Polyhedral Solids.—In the study of solids aid is obtained from the study of a special class, polyhedral solids, *i.e.*, solids bounded by configurations formed by polyhedra. The theory of polyhedra suggests means of classifying more general solids and also methods of attack in the solution of problems of more general solids. Furthermore, the fact that any solid can be approximated to as closely as desired by a polyhedral solid adds to the impor-

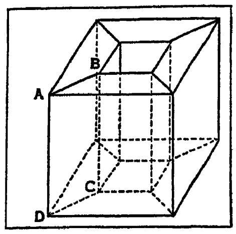
tance of the theory of such solids to a study of solids in general. A precise formulation of the fact just alluded to is the following: If S denotes any solid, then there exists a sequence of polyhedral solids, $P_1, P_2, P_3, \ldots, P_n \ldots$, such that every point of the solid P_n is a point of the interior of S and also of the interior of the solid P_{n+1}, and every point of the interior of S is a point of the interior a polyhedral solid P_m of the sequence. In particular, there exist such sequences of polyhedral solids such that each polyhedral solid is composed of a finite number of cubes such that no two of the cubes have interior points in common and every cube has a face in common with another one of the cubes. Another method of approximating to a solid by means of polyhedral solids is that in which the vertices of the approximating polyhedral solids are points of the boundary of the given solid, or, as it is usually stated, the polyhedron which bounds the polyhedral solid is inscribed in the boundary of the given solid. However, the existence of sequences of approximating polyhedral solids of the latter kind has been established only in the case of special solids.

POLYHEDRA

Definitions.—According to the definition of polyhedral solids, it is immediately evident that the theory of polyhedra is of much importance in the study of those solids. Preparatory to the consideration of the properties of polyhedra the following definitions are made. A *segment* is the set of all points of a (straight) line which are between two points of that line, and each of the latter points is called an *end* of the segment. A *simple polygon* is a finite set of points (*vertices* of the polygon) and segments (*sides* of the polygon) such that (a) each point of the set is the end of two and only two segments of the set, (b) the ends of each segment of the set are points of the set, (c) no two elements (*i.e.,* points or segments) of the set have a point in common, and finally (d) no proper subset of the set of points and segments satisfies (a), (b) and (c). It is a theorem of euclidean plane geometry that every simple polygon in a plane π is the planar boundary of a unique connected region of finite extent which is contained in π. The planar boundary of a set of points in a plane and a connected region in a plane are the two-dimensional analogues of the boundary of a solid and the interior of a solid respectively as defined above, circles of the plane replacing the spheres in the definitions referred to. Saying that a set of points is of *finite extent* means that it is contained in the interior of a sphere. The planar region thus determined by a simple plane polygon is called a *polygonal region.*

A finite set of points, segments and polygonal regions is called a *polyhedron,* if and only if (a) every segment of the set is a side of the boundaries of two and only two polygonal regions of the set, and every side of the boundary of a polygonal region of the set is a segment of the set, (b) every point of the set is an end of at least one segment of the set, and the ends of any segment of the set are points of the set, (c) if P is any point of the set, the set σ of all polygonal regions of the set whose boundaries have P as a vertex form a cycle, *i.e.,* every segment of the set which has P as an end is a side of the boundaries of two polygonal regions of the set σ and no proper subset of σ has that property, (d) no two elements (*i.e.,* points, segments or polygonal regions) of the set have a point in common, and (e) there is no proper subset of the set of points, segments, and polygonal regions which satisfies (a), (b), (c) and (d). By omitting some of the conditions of this definition, more general configurations which are also called polyhedra are defined thereby, and the set just defined is called a *simple* or an *ordinary polyhedron.* Just so there are polygons which are not simple and which are defined by less restrictive definitions than that given above. In what follows, the words polygon and polyhedron signify respectively, simple polygon and simple polyhedron. Despite the qualifying term simple, the class of simple polyhedra has a most interesting and important theory which still leaves much to be done.

Non-metrical Properties.—That every polyhedron is the boundary of a unique solid of finite extent and also the boundary of a unique solid not of finite extent is a theorem of euclidean three-dimensional geometry which requires a proof of considerable length. This theorem is analogous to the theorem of euclidean two-dimensional geometry concerning the separation of a plane by a polygon contained in it; but at this point the spatial theory becomes much richer. Considering merely the internal connection of the elements of a polygon, one is very much like the other, but in the case of polyhedra that is not so. Besides polyhedra such as the tetrahedron, cube octahedron, etc., there are those which can be obtained by cutting one or more square holes out of the limited solid bounded by a cube, tetrahedron, etc. Between a polyhedron thus obtained and a cube or tetrahedron there is a fundamental difference. The diagram illustrates one of these polyhedra of more complicated structure. It consists of 16 vertices, 32 edges and 16 faces. In the case of a cube any polygon P consisting of vertices and edges of the cube separates the cube; *i.e.,* there is a pair of points (and, of course, many pairs) of the cube, which do not belong to any polygonal line which is made up of points of the cube and which contains no points of the polygon P. (It should be emphasized that the terms cube, tetrahedron, octahedron, etc. are used here to denote polyhedra and not solids bounded by certain polyhedra.)



In the case of the polyhedron of the illustration the polygon $ABCDA$ does not separate that polyhedron in the above sense; however, any pair of polygons contained in the polyhedron, *i.e.,* every vertex and every point of the sides of the polygon, are points which are either vertices or belong to edges and faces of the polyhedron, and having no points in common separates the polyhedron in the sense that a set S of polygons separates a polyhedron π if the polygons of S are contained in π and if there are two points of π such that any polygonal line which contains them and which is contained in π also contains a point of a polygon of S. For any polyhedron there exists a finite set T of polygons which have no points in common and such that the set T does not separate the polyhedron, while any set of non-intersecting polygons on the polyhedron, which contains more polygons than T, separates the polyhedron. The number of polygons in the set T is called the *genus* of the polyhedron. Thus it can be easily shown that the cube, tetrahedron, and the more common polyhedra are of genus zero, while the genus of the polyhedron of the above illustration is one. Speaking roughly, a polyhedron of genus p is not disconnected when it is cut along the circuits (polygons) of a certain set of p circuits, but it is disconnected when cut along any $p+1$ circuits.

A most important theorem may now be stated. If $v=$ the number of vertices, $e=$ the number of edges, and $f=$ the number of faces of a polyhedron of genus p, then $v-e+f=2-2p$. Thus in the case of the polyhedra of genus zero (such as the cube, octahedron, and icosahedron) $v-e+f=2$, while for the polyhedron illustrated above $v-e+f=0$. The number $v-e+f$ is called the *characteristic* of the polyhedron. A remarkable fact in this connection is that, if two polyhedra have the same characteristic (or genus), then a subdivision of the elements of each exists so that the polyhedra thus derived are isomorphic; *i.e.,* any vertex, edge and face of one is paired respectively with a vertex, edge and face of the other such that a pair of elements of the first polyhedron which are incident corresponds to a pair of elements of the second polyhedron, which also are incident, and conversely. Thus, if a vertex A' and an edge a' of the second polyhedron are paired with the vertex A and the edge a of the first polyhedron respectively, and if A is an end of a, then A' is an end of a'; and similarly if a vertex and a face or an edge and a face are incident. The integer 2 minus the characteristic of a polyhedron is known as the *connectivity number* of the polyhedron and, as implied above, for a polyhedron in euclidean three-dimensional space it is either positive and even, or zero.

Classes of Polyhedra.—In the theory of polyhedra, considered merely as sets of objects, called vertices, edges and faces, which satisfy the relations of incidence and order of the definition of a polyhedron given above and which are not sets of points in any particular space, it is shown that there exists a polyhedron having any positive integer or zero as its connectivity number. In this

theory two classes of polyhedra are distinguished. Any polyhedron of one of these classes has the property that there is at least one polygon on it which does not separate any region which is on the polyhedron and which contains the polygon. The term region is used here in a sense which, though analogous to, is a simple extension of, its meaning given above. All other polyhedra make up the other class. Polyhedra of the latter class are sometimes said to be *two-sided;* those of the former *one-sided.* The basis of this terminology is suggested above in reference to the separation of euclidean space by polyhedra. Only two-sided polyhedra exist in euclidean space and any two-sided polyhedron is isomorphic with a polyhedron in euclidean space. A generalized polyhedron (*see* below) in euclidean space may be one-sided.

The terms *non-orientable* and *orientable* are also applied to polyhedra of the former and latter classes respectively, because either of two senses can be defined on an orientable polyhedron just as in the case of the euclidean plane or sphere, while that is impossible in the case of so-called non-orientable polyhedra. In the general theory of polyhedra, also called *manifolds* (*q.v.*) in that context, the above equation relating v, e, f and p holds for all orientable polyhedra, while the equation $v-e+f=2-p$ is the corresponding equation for non-orientable polyhedra, the letters in both cases having analogous meanings. In the following, as in what preceded this digression, it is understood that the polyhedra are in euclidean three-dimensional space, and are therefore two-sided or orientable.

Classification of Polyhedra.—It is suggested immediately that polyhedra may be classified according to genus but then the question of a finer classification arises. The goal is the complete description of the classes so that any two polyhedra of the same class and no two of different classes are isomorphic. Each of the classes of such a classification shall be called a *type.* It is obvious that the polyhedra of the same class have the same genus, but that the converse is not true. It is also obvious that polyhedra which are not isomorphic may form the boundary of the same solid. No such exhaustive classification has ever been completed, not even for the class of all polyhedra of genus zero.

A most useful general method of thus classifying polyhedra is based on the problem of the determination of all types of polyhedra of $f+1$ faces or $v+1$ vertices, assuming that all the types of polyhedra of f faces or v vertices, respectively, are known. For example, any type of convex polyhedron (for definition *see* below) of $f+1$ faces can be obtained by cutting with a plane all the faces of a certain convex polyhedron of f faces, which are incident with the same vertex. In the case of the special convex polyhedra which have only vertices which are incident with three and only three edges, this process of "cutting off the corners" results in a polyhedron of the same speciality and gives a comparatively complete result. If $\psi(f)$ denotes the number of types of convex polyhedra which have f faces and all of whose vertices are incident with exactly three edges, then $\psi(4)=1$, $\psi(5)=1$, $\psi(6)=2$, $\psi(7)=5$, $\psi(8)=14$, $\psi(9)=50$, and $\psi(10)=233$.

Very little, indeed, is known of the general behaviour of the function $\psi(f)$. If the polyhedra also satisfy the special condition that each polyhedron contains a face which is adjacent to all of the remaining faces, then a recursion formula for the value of $\psi(f)$ is known, but even in this very special case it is sufficiently complicated. A similar degree of completeness exists in the theory of the convex polyhedra, *i.e.,* the so-called duals of those just considered, *i.e.,* those which have only triangular faces. A polyhedron is said to be the dual (*see* DUALITY) or *reciprocal* of another if each vertex of the former is paired with a unique face of the second, so that thereby every face of the second is paired with just one vertex of the first, and if each edge of the first is paired with a unique edge of the second in a reciprocal way, and if a pair of incident elements of the second polyhedron corresponds to a pair of incident elements of the first.

Another general procedure in studying different types of polyhedra consists of making simple replacements of some of the elements of a polyhedron by new elements. For example, a face may be replaced by the two faces and the edge, which result from the division of the original face by a line which cuts its boundary in exactly two points, and different replacements are made according as the dividing line passes through no vertex, one vertex or two vertices incident with the face. For some such replacements the type of the polyhedron is not changed, while for others the type of the resulting polyhedron is different from but simply related to that of the original one. Many important theorems result from the consideration of such replacements of elements.

Regularly Connected and Convex Polyhedra.—In the case of certain special but important classes of polyhedra, the general ideas considered above lead to quite complete information about those classes. An important sub-class of polyhedra is that which consists of regularly connected polyhedra. A polyhedron is said to be *regularly connected* if every pair of vertices of the polyhedron which are incident with two of its faces are the ends of an edge of the polyhedron, which edge is also incident with those two faces. The type of a regularly connected polyhedron is completely determined by the incidence relations of its vertices and faces. Also, if the boundary of a face of a regularly connected polyhedron is removed the remaining set of vertices and edges is connected, but the converse, as is easily seen, is not true. It is interesting to note that the converse of the original statement with the phrase "regularly connected polyhedron" replaced by "polyhedron of genus zero," is true but not the modified statement. Finally there is the important special case of a regularly connected polyhedron of genus zero. Such a polyhedron will be said to be *convex-like,* because with regard only to incidence relations of its elements it does not differ from a convex polyhedron. The precise fact is given in the fundamental theorem that every convex-like polyhedron is of the same type as that of a certain convex polyhedron. As an important preliminary theorem here we have that every convex-like polyhedron is derivable from a tetrahedron by simple replacements of elements such as referred to above.

A convex polyhedron, already referred to several times, is defined in several equivalent ways. One definition requires that no line which is not in the plane of any face of the polyhedron contains more than two points of the elements of the polyhedron, and another is that, if α is any face of the polyhedron, then all of the elements of the polyhedron except α and the vertices and edges incident with α are on the same side of the plane which contains α. Again, a polyhedron which forms the boundary of a convex solid is a convex polyhedron, where by a *convex solid* is meant a solid which is such that, if two ends of a segment are points of the solid, then every point of the segment is a point of the solid. It is worth noting that these definitions require that a convex polyhedron be contained in a three-dimensional space, while the concept of a convex-like polyhedron is independent of any surrounding space.

Some further results of the foregoing will now be noted. If v, e and f respectively denote the number of vertices, of edges and of faces of a polyhedron then, since at least three edges are incident with each vertex and also with each face, $3v \leqq 2e$ and $3g \leqq 2e$; and if the polyhedron is of genus zero, then $v-e+f=2$. Conversely, it is proved that, if v, e and f are positive integers which satisfy these three conditions, the two inequalities and the equality, then there exists a polyhedron, in particular a convex polyhedron, with v vertices, e edges and f faces. Further, it follows easily from the latter equality that every polyhedron of genus zero and, therefore, in particular every convex polyhedron (for it is shown easily that the genus of a convex polyhedron is zero) has at least one face that is bounded by a polyhedron of either 3, 4 or 5 sides, and at least one vertex which is incident with 3, 4 or 5 edges, and has at least either one triangular face or one trilinear vertex, *i.e.,* a vertex incident with exactly three edges. Also, there exist polyhedra and. in particular, convex polyhedra having any number of edges, if that number is an integer greater than five and different from seven. There is no polyhedron having exactly seven edges. Finally a fact that is remarkable (even in view of the greater richness of the theory of polyhedra in euclidean three-dimensional space as compared to the theory of polygons in a plane) is that there exist polyhedral solids, evidently not convex, in

euclidean three-dimensional space, which are not decomposable into a finite number of tetrahedral regions which have no points which are not on their boundaries in common, and whose vertices are vertices of the polyhedral solid. That an analogous decomposition of a polygonal region into triangular regions always exists is a theorem of euclidean plane geometry.

Metrical Properties of Polyhedra.—The preceding exposition has been concerned largely with non-metrical properties. In succeeding paragraphs metrical properties of polyhedra are also considered. These properties being based on the intuitive notions of size and shape were the chief objects of study in the very early development of the subject. The chief topics here are the congruence of polyhedra and the properties of polyhedra which have elements or groups of elements which are congruent respectively. Two configurations are said to be *congruent* in the narrow sense if, and only if, one can be transformed into the other by a rigid motion. Two configurations are said to be congruent in the broad sense if, and only if, one can be transformed into the other by a succession or product of a finite number of rigid motions and planar symmetries; *i.e.,* reflections in a plane. An equivalent set of definitions is the following: Two configurations are congruent in the broad sense if, and only if, the points of one are in one-one correspondence with the points of the other such that the distances between pairs of corresponding points are equal. If sense as well as distance is preserved by the correspondence, then and only then are the two configurations congruent in the narrow sense. The terms of these definitions have precise abstract meanings but in order to save space they are omitted here; their ordinary meanings should give a sufficient understanding.

An outstanding theorem on the congruence of polyhedra is that if two convex polyhedra are isomorphic such that corresponding faces are congruent, then the polyhedra are congruent in the broad sense. The theorem is obviously not true in the case of polyhedra which are not convex, and an interesting theory concerning the infinitesimal and finite deformations of non-convex polyhedra, which preserve length, presents itself.

Regular and Semi-regular Polyhedra.—The question of the congruence of polyhedra suggests the consideration of a single polyhedron whose elements satisfy certain relations of congruence. At the extreme of speciality there are the so-called regular polyhedra. Because of their very conspicuous regularity they are among the oldest objects of study in the theory of polyhedra. A polyhedron is a *regular polyhedron* if, and only if, the boundary of each face is a regular polygon which is congruent to the boundary of every other face and each polyhedral angle of the polyhedron is regular, *i.e.,* having congruent face angles and dihedral angles resp., and congruent to every other polyhedral angle of the polyhedron. There are exactly five types of regular polyhedra; further details of these are given in the table below. A generalization of the regular polyhedra are the *Archimedian polyhedra;* all the faces of such a polyhedron are bounded by regular polygons, not all congruent to each other, and all the polyhedral angles are convex and congruent to each other. There are thirteen types of such polyhedra besides the semi-regular prisms and prismoids.

A *prism* is a polyhedron of which two faces, called its bases, lie in parallel planes and each of the remaining faces is bounded by a parallelogram and is adjacent to each base. A *prismoid* is a polyhedron which also has two faces, its bases, which are in parallel planes, while each of its other faces is triangular and incident with a vertex of one base and a side of the other. If every face of a prism or prismoid is regular, *i.e.,* bounded by a regular polygon, and if the bases of the prismoid are congruent, then the prism or prismoid are said to be semi-regular. The Archimedian polyhedra and their reciprocals form the class of the so-called *semi-regular polyhedra.* The semi-regular polyhedra can be obtained by such simple operations as taking plane sections of and combining regular polyhedra, and by dualizing. For example, the cuboctahedron is obtained by cutting off the vertices of the cube or octahedron by planes passing through the mid-points of the edges; the icosidodecahedron by a similar treatment of the dodecahedron or icosahedron. The reciprocals of these two Archimedian polyhedra are respectively the rhombic-dodecahedron and the rhombic triacontahedron, which have in all twelve and thirty faces respectively, each face being a rhombus. For further details of semi-regular polyhedra, *see* table p. 945.

The idea of semi-regular polyhedra leads to the later generalization of the notion of regularity, which is contained in the idea of a polyhedron transformable into itself by a congruence transformation, in the broad sense, such that any polyhedral angle of the polyhedron is transformed thereby into any other. Reciprocally there is defined a polyhedron which is transformable into itself by a congruence transformation so that any face of the polyhedron is transformed into any other. Polyhedra of the former kind have a circumscribing sphere while those of the latter have an inscribed sphere. The mere requirement of the congruence of all of the polyhedral angles or of all of the faces of a polyhedron does not imply the existence of a circumscribing or an inscribed sphere respectively. Archimedian polyhedra are polyhedra of the former kind which have their faces bounded by regular polygons which are not all congruent to each other. A complete classification of the convex polyhedra satisfying this more general definition of regularity has been made, according to the kind of faces and the various relations of symmetry which are satisfied, and the number of distinctive types is finite. When the requirement of convexity is removed the complexity of the problem of classification is very great, and no classification of any satisfying degree of completeness has been made. In conformity with the present viewpoint a regular polyhedron may be defined as a polyhedron which is transformable into itself by a congruence transformation, in the broad sense, so that any vertex is transformed into any other vertex, any edge incident with the former vertex into any edge incident with the latter vertex, and any face incident with the former edge into any face incident with the latter edge.

The notion of symmetry furnishes another basis for the investigation of properties of regularity of polyhedra. It is a fundamental concept in the definition of an important class of polyhedral solids known as crystals. A configuration is called *symmetrical* if it admits of a congruence transformation, in the broad sense, into itself, which is not the identity. In this scheme of classification, two configurations are in the same class if the group of congruence transformations which transform one of the configurations into itself is the same as the group of congruence transformations which transform the other into itself.

A Crystal.—A *crystal* is a solid whose boundary is a polyhedron which has the following properties: In the first place its vertices, edges and faces are respectively on points, lines and planes of a rational space net. A rational space net is the set S of all points, lines and planes such that there are five points, P_1, P_2, P_3, P_4 and P_5, no four of which are in a plane, such as the vertices of a tetrahedron and a point interior thereto, with the property that if α denotes any element (point, line or plane) of S, then there exists a finite sequence of elements of S, $P_1, P_2, P_3, P_4, P_5, \alpha_1, \alpha_2, \alpha_3, \ldots, \alpha_n, \alpha$, such that the first five elements are the five points mentioned above and any other element of the sequence is uniquely determined by being common to or containing preceding elements of the sequence. Secondly, the polyhedron is transformed into itself by the transformations of a finite group of congruence transformations, in the broad sense, which transform a rational space net into itself. Such a group is known as a crystallographic group. There exist thirty-two crystallographic groups which thus determine the same number of classes of crystals.

Generalized Polyhedra.—At this point, perhaps, there should be mentioned a generalization of the notion of regular polyhedron, which is obtained by generalizing the idea of a polyhedron itself, although these generalized polyhedra are not the boundaries of unique solids. The boundary of a face of a polyhedron is, as stated early in this article, a simple plane polygon. A *generalized polygon* satisfies the conditions of the definition of a simple polygon, except that one which states that no elements of the polygon have a point in common. (One might generalize further by requiring an even number, not necessarily two, of sides inci-

dent with each vertex.) A *regular generalized polygon* is defined accordingly; *e.g.,* any regular generalized polygon, sometimes called a *star polygon,* with n vertices is obtained by joining in order every k th vertex of a regular simple polygon of n vertices, where k is any integer between 1 and $n/2$.

In an analogous way the notion of a *generalized polyhedron* is defined; *i.e.,* by relinquishing the condition that two elements have no points in common, and at the same time allowing a face to be determined by a generalized plane polygon. The generalized polygon is not the boundary of the face in the ordinary sense. For example, the sides of each pentagon which bounds a face of a regular dodecahedron when prolonged form a star pentagon, and all such star pentagons determine the faces of the great dodecahedron. The latter generalized polyhedron is regular in a sense which is an obvious extension of the meaning of that term as applied to ordinary polyhedra. There are just four such *regular generalized polyhedra* and detailed data concerning them are given in an accompanying table. The other definitions involving the idea of regularity as applied to ordinary polyhedra evidently admit of like extension so as to apply to generalized polyhedra, and many interesting types of generalized polyhedra accordingly present themselves.

Explanation of Tables.—The symbols of the tables have the following meanings: f denotes the number of faces of the polyhedron, v the number of vertices, and e the number of edges; of the f faces, m_1 are bounded by polygons of m sides, and m_2 of these m_1 faces are incident to each vertex. Similarly, in the case of the numbers n, n_1, n_2 and s, s_1, s_2. a is the number of times that the projection of the generalized polyhedron from its centre on to a sphere about that centre covers the sphere; a_1 and a_2, are respectively the analogous numbers for a polygon which determines a face of the polyhedron, and for a polyhedral angle of the polyhedron; p is the genus of the polyhedron (the genus of all polyhedra in the first table is, of course, zero). Each polyhedron of a bracketed pair is dual to the other; the tetrahedron is self-dual.

GEOMETRIC SOLIDS IN GENERAL

The boundary of a solid may consist, of course, of several polyhedra; *e.g.,* a cube and one or more smaller cubes inside of the former. Some of these polyhedra may have points in common. The great diversity of such disconnected boundaries makes classifying them difficult; a rough classification is according to the number of pieces into which the boundary falls. As remarked earlier, the boundary of a solid may be a closed surface or consist of a number of such, or it may be a set of points of great irregularity. Solids with such irregular boundaries can be obtained by limiting processes in which certain constructions are repeated an infinite number of times.

The study of the general properties of solids of the class of solids whose boundaries are closed surfaces is made along lines suggested by the theory of polyhedral solids, a sub-class of the former; for a closed surface can be transformed continuously into a polyhedron. This property may be taken as the defining property of a closed surface. The concept of genus carries over directly, when simple continuous curves are used in place of the polygonal lines and polygons of the definition of that term given above. Simple examples of closed surfaces are the sphere, ellipsoid, the surface of a cone, of a cylinder, and of an anchor ring, *i.e.,* a torus. With regard only to the primitive properties of continuity and connectivity, the first four closed surfaces are not different; the torus, however, is different from all of the other four. The genus of each of the first four is zero, that of the torus, one; it is impossible to transform continuously the torus into any of the others, but any one of the first four can be continuously transformed into any other. The similarity between the torus and the polyhedron illustrated above should be noted; the genus of each is unity and either is continuously transformable into the other. When projective or metric properties are regarded, distinctions between any two of the examples cited immediately appear. (*See* MATHEMATICAL MODELS.)

SOLID STATE, THEORY OF. It is often said that a solid has volume and shape, a liquid volume, but no shape, and a gas neither definite volume nor shape. Though it sums up neatly the main characteristics of the three states of aggregation, this statement scarcely forms an accurate or adequate definition. The volume of both solids and liquids can be modified, if only to a slight degree, by external pressure. Similarly the shape of a solid can be changed by applied forces. Conversely, a liquid unstrained, has the tendency to assume a spherical shape, though it is true that this tendency is slight. Again large masses of gas under the influence of the mutual attraction of the molecules, tend to form those vast spheres which we know as stars. The definitions, such as they are, describe in reality the viscosity and

surface tension, rather than the state of aggregation. Nevertheless, they form a rough working picture upon which a more searching examination may be based.

From the molecular point of view the three states of aggregation of matter may be described in terms of the forces acting between the molecules. Besides the ordinary gravitational attraction, there is as is well known, a molecular force of attraction

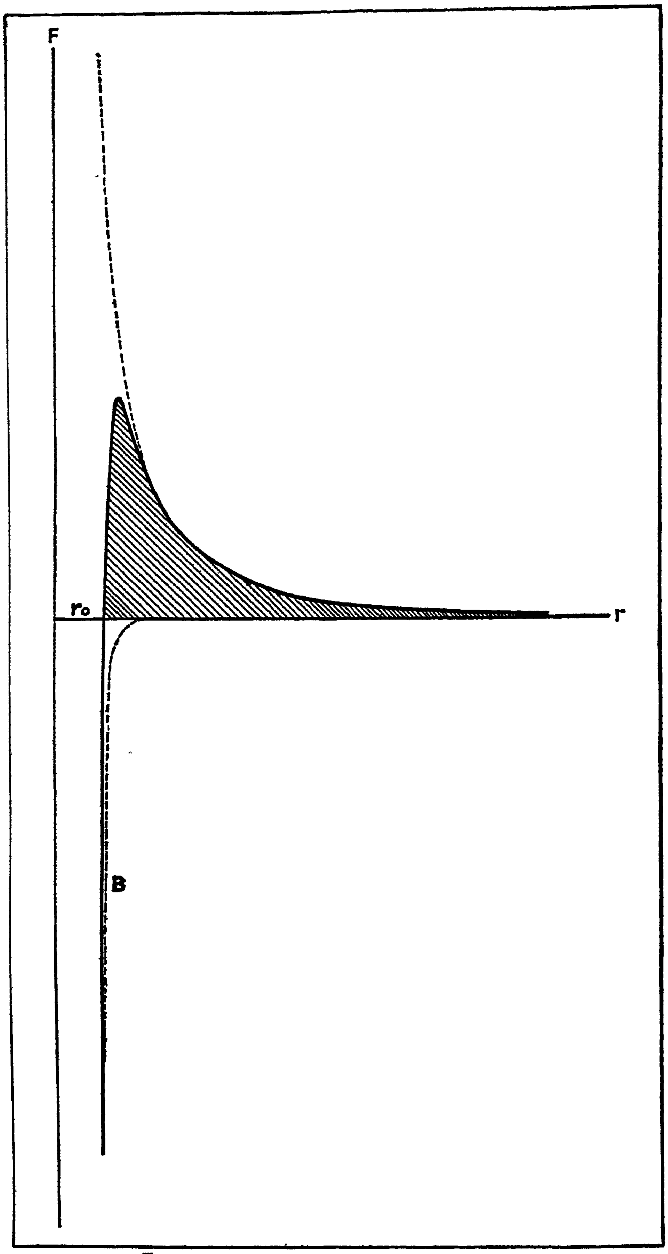

FIG. 1.—FORCE BETWEEN ATOMS IN SOLIDS

or cohesion which comes into play at distances small compared to our ordinary standards, but large compared to the molecules themselves. This force of attraction which is probably electromagnetic in origin, may be represented by the curve A as shown in fig. 1, which diminishes with considerable rapidity as the distance between the molecules measured along the abscissa increases. When the molecules approach very close to one another there is a force of repulsion which philosophers, though not perhaps physicists, might attribute to the unscientific axiom, that two things cannot occupy the same place at the same time. This force is undoubtedly closely related to what may be called the shape of the molecule and is presumably due to the mutual repulsion of the peripheral negative electric charges. Whatever its origin, it is undoubtedly very small until the molecules approach one another within a distance comparable with their own diameter where it rapidly becomes extremely large. If this force be represented by curve *B* then it is evident that the interplay of the attraction and repulsion lead to a force of repulsion when the molecules approach one another within a given distance which changes over to a force of attraction as this distance is exceeded. On increasing the distance the attraction increases until it attains a maximum value after which it rapidly diminishes to become negligible at distances large compared to the molecular diameter.

The existence of forces between molecules which may be represented by curves of this type explains the existence of the three states of aggregation to matter. If the energy of the molecules is large compared to the total energy necessary to separate them from their closest approach to infinity, then the substances will be in the gaseous state for the collisions will be so violent that the particles rebound without coalescing. When the energy is diminished the violence of the collisions decreases and occasions will arise when the molecules coalesce and ultimately condense to a liquid. In the liquid the molecules move about rapidly colliding with one another, but only in exceptional cases have they enough energy to overcome the attraction of the surface molecules and to escape into the vapour phase. Their velocities being distributed, according to Maxwell's expression, there will always be a few with the necessary abnormally large energy; in general however these form only a small fraction of the whole, a fraction which varies of course with the temperature and is a measure of the vapour pressure.

It may be remarked that the energy required by a molecule, to enable it to overcome the attraction of all its neighbouring molecules at the surface of a liquid is greater (though only about three times greater) than the work necessary to separate two molecules from contact to infinity. This explains the phenomenon of supersaturation. If no drop of liquid is present, only molecules will coalesce whose relative speed when they collide is so small as to be insufficient to overcome their mutual attraction. As soon as a drop of liquid is formed all these comparatively slow molecules will condense upon it; for to escape from the attraction of all the molecules in a surface requires considerably more energy than to prevail over the attraction of a single molecule.

The solid state is that in which the energy of the molecules is insufficient to overcome their mutual repulsion sufficiently to enable them to collide. This distinction between mutual repulsion and collision presupposes an enormously rapid increase in the force at a given point corresponding to the distance which, in old fashioned language, would have been called the surface of the molecule. This very rapid increase certainly exists; exactly what causes it we need not here consider. At low temperatures when the energy of the molecules is small they will approach one another until their average distance is such that their mutual attraction balances their mutual repulsion, in other words, until their mean distance corresponds to the point at which the curve cuts the axis in fig. 1. About this position of equilibrium the molecules oscillate under the influence of their mutual repulsion. As the temperature rises the magnitude of their excursions increases until the molecules reach a point at which the mutual repulsion becomes suddenly very large, in other words until they collide.

We must here call attention to the fact that there are two very definite classes of so-called solids, the crystalline and the amorphous solids. If one considers a number of molecules of similar type acting upon one another as described above it is clear that the most stable arrangement will be that in which the attractive forces have been able to exert themselves to the full, in other words the molecules will tend to arrange themselves in the closest packed order. If the fields of forces are symmetrical the closest packed form will correspond to the closest arrangement of a number of spheres. As has been known ever since cannon balls were piled into heaps, this closest array corresponds to a pyramid. Hence molecules with symmetrical fields of force will tend to arrange themselves in octahedral order, and will form a regular space-lattice. If the fields of force are not symmetrical they will still form a space-lattice, but the distance between them will not be the same along different axes, the axes will not

be orthogonal, and the substance will not crystallize in the regular system. The crystalline state is characterized by the arrangement of molecules at regular intervals in the most stable condition.

One might almost question whether the amorphous bodies, sometimes called glasses, should properly be classed as solids. They are, strictly speaking, undercooled liquids and are formed when cooling from the liquid state takes place too rapidly for the forces of attraction to have time to collect the molecules into their most stable positions. In this state the positions of the molecules are irregular, though of course their average distance is not very much greater than in the crystal. They are close together but not equally spaced, they correspond to a crowd rather than to a regiment. When the attraction is great even the most rapid cooling may not suffice to prevent the molecules arranging themselves in regular order. If the energy to be gained by arranging them in regular array is not very great, *i.e.,* if the work of attraction is not very much greater than the work of repulsion, there is no great tendency to crystallize, and the substance may be supercooled, that is to say, solidified in the amorphous form even though cooled comparatively slowly. This is particularly likely to happen when one has large irregular molecules, especially if they are not all alike. Thus in the case of glass only a very prolonged exposure to an appropriate temperature causes devitrification, *i.e.,* crystallization to occur. Temperature in this connection is of supreme importance, for at low temperatures the energy of the particles is too small to enable them to make excursions from their position of equilibrium which might in favourable circumstances result in their changing places and achieving a more stable regular arrangement. It is high temperatures near, but not too near, the melting point where the viscosity is low, that favour crystallization.

Having defined these two classes we may examine the transition from the solid to the liquid state. As a crystal is heated the amplitude of the oscillations of the molecules about their positions of equilibrium increases until those molecules with an exceptionally high energy content collide with their neighbours. Such a collision results in the sharing of the momentum with a neighbour and the distribution of the energy between the two molecules. In this way the crystal may be heated without any material change until the temperature is reached at which the average amplitude of oscillation is such that all molecules collide. At this temperature sharing the energy does not diminish the oscillation below the point of collision and the whole structure collapses into a liquid. Thus the crystals have a perfectly well defined melting point which cannot be exceeded. No crystal can be heated in any circumstances above the melting point.

The amorphous bodies behave very differently. As the energy of the molecules is augmented the amplitude of oscillation of those which happen to be so placed that their neighbour's repulsion is small, increases very rapidly. In favourable circumstances, here and there collisions take place at temperatures well below that of liquefaction proper. The number of these go up rapidly as the temperature is raised. What might be called local liquefaction occurs in innumerable minute regions dispersed at random through the body. It becomes soft and viscous and changes gradually by imperceptible degrees into a liquid. It is precisely this property which gives glasses their valuable qualities. A temperature can always be found at which their viscosity is such that they can be worked and moulded, into any desired shape or form. From a scientific point of view this condition is less satisfactory; glasses have no definite melting point and in their case the solid state can only be defined as that in which few of the molecules have a sufficent amplitude of oscillation to collide.

Thus we see that the characteristic of having shape, in the case of a solid reduces to the fact that the molecules are held in position by the forces they exert upon one another, whether in regular array as in a crystal, or distributed irregularly as in a glass, until external agencies intervene. Unless forces large compared to the molecular forces are applied no great movement of the molecules or change in the shape can be expected. The effect of smaller forces, as might be expected, is to modify slightly the relative positions of the molecules. If, say, a solid is subjected to pressure from all sides this corresponds to a general increase of the attractive forces. The positions of equilibrium approach one another, the solid is compressed into a smaller volume. The compressibility is thus a measure of the forces holding the molecules in their positions of equilibrium. Its small value shows how large these forces are.

There is one very remarkable class of objects, the metallic crystals in which the stress necessary to produce a change of shape is comparatively small. It has been found that metals which normally consist of an agglomeration of small crystals may be converted into large single crystals by alternate stretching or heating at appropriate temperatures. These single crystals exhibit a very small resistance to deformation, so much so that they are apt to bend and break up under their own weight. The reason for this abnormal behaviour has not been clearly established, though it is possible that it is due to the constitution of the metallic space-lattice. Reasons have been adduced for the view that this consists of two interleaved lattices, one consisting of electrons and the other of the ions formed by their dissociation from the parent atoms. It has been suggested by Hume-Rotheray that such a lattice consisting alternately of particles of finite size and particles of comparatively negligible size would have a very small resistance to deformation.

The best known characteristic of crystals is their regular shape. This is readily explained on the view put forward above. The number of atoms in any given volume being fixed, the distance between planes of closely packed atoms must be greater than the distance between planes in which the atoms are farther apart. If the attractive force between the atoms diminishes with distance, the strength of the crystals at right angles to such a closely packed plane must be a minimum and hence cleavage will tend to occur along such a plane. The same argument explains why molecules which are deposited upon a crystal will seek out this plane and thus give rise to the shapes so well known to crystallographers.

The mutual attraction of the molecules gives rise of course on the surface of a solid to an uncompensated inward attraction which is known in liquids as surface tension. This corresponds to an external pressure of a very considerable amount. Its order of magnitude may be gauged by considering the work consumed in causing the solid to expand. The amount which varies from substance to substance is measured in tens of thousands of atmospheres. Connected with this, in theory though not in practice, is the tensile strength of a solid. As shown by the curve, the attraction between two neighbouring molecules grows as they are removed from one another up to a limit after which it decreases. This limit should be a measure of the ultimate strength of the material and the point at which it is reached should bear some relation to the maximum tension. Though we do not know the exact form of the curve an estimate of the amount can be made. The shaded area represents the work done in removing a molecule to infinity, *i.e.,* the latent heat of evaporation which of course is known; the angle under which the curve cuts the abscissa, gives the measure of the restoring force acting upon the molecules; as mentioned above, it is related to the compressibility. An estimate of the theoretical strength of some of the metals is some twenty or thirty times higher than anything observed, presumably because the metals form an agglomeration of small crystals and their tensile strength no more gives a measure of the ultimate forces between the molecules than does the strength of a piece of wool, of the fibres composing it. Tensile strengths of the theoretical order of magnitude are found in glass immediately after and in silica for some hours after drawing in a flame. This presumably represents the period before submicroscopic crystallization sets in.

The forces acting upon a molecule in the interior of a solid, are obviously equal from all sides when it is in its position of equilibrium. No matter what the law of force may be a small displacement from this position will give rise to a restoring force proportional to the displacement. For by Taylor's Theorem, the function of a given argument, plus a small quantity, is equal to the function of the argument plus the small quantity multiplied

by the derivative of the function. Since the forces from both sides are equal at equilibrium and the small displacement corresponds in the one case to an addition to, and in the other a subtraction from the argument, the resultant restoring force is twice the derivative of the function multiplied by the displacement. This result which of course means no more physically than that every curve may over a sufficiently small distance be treated as a straight line, is the reason for the approximate validity of Hooke's law, that the strain is proportional to the stress, the extension to the applied force or the compression to the applied pressure. Though accurate to a first approximation, it has long been known that it is really only true as a limiting case for small forces.

As will appear below several important characteristics of solids depend entirely upon the deviations from the simple linear expression. If one confines oneself to the first order and considers only a quasi-elastic restoring force α and it follows that the molecules in a solid will oscillate with a definite proper frequency

$$\nu = \frac{1}{2\pi}\sqrt{\frac{\alpha}{m}},$$

m being their mass. The reality is not quite so simple since the motion of one molecule will be communicated to its neighbours and the whole system will quiver with a number of different proper frequencies which depend upon the lattice structure, the force between the molecules and the molecular weight. The highest frequency, however, will be that given by the above formula for a body of mass m vibrating under the elastic restoring force α. This can be observed directly in solids which contain ions. In the case for instance of rock salt or sylvin, the crystal is built up of a cubical array of alternating alkali ions and halogen ions. The restoring forces acting on these may be derived from the compressibility, and their mass, the atomic weight divided by Avogadros number, is of course known. Hence their frequency of oscillation can be calculated; for NaCl it is about -6×10^{12} and for KCl about 5×10^{12}. If an alternating electromagnetic field, in other words, radiation of this frequency, is allowed to fall upon these crystals the ions, being in resonance, are set in motion and the radiation is reflected.

Another method of estimating molecular frequencies makes use of the definition of the melting given above, namely that the melting point is the temperature at which the amplitude of oscillation of the molecules enables them to collide with one another. As in the case of a musical string or pendulum, the amplitude of oscillation is completely determined if the mass, frequency and energy are known. Since the energy at the melting point and the atomic mass are ascertainable, the frequency can be derived if the free space between the molecules is known. Conversely if the frequency is known the amplitude of oscillation at the melting point, in other words the distance between the surfaces of the molecules, can be calculated. It appears to be much the same fraction in all monatomic substances, 10% to 12% of the distance between the centres of neighbouring atoms.

The frequencies are of importance, since it has been shown by Einstein following Planck, that they determine the course of the specific heats of substances at low temperatures. The classical statistical mechanics of Boltzmann, showed that the mean kinetic energy resolved along any one axis of particles capable of motion and capable of interchanging momentum, averaged over the time, should be equal provided the particles are in thermal equilibrium, *i.e.*, at the same temperature. Hence the molecules in a solid, since they are capable of oscillation along each of three axes, just as the molecules in a gas are free in three dimensions, should contain the same amount of kinetic energy as a monatomic gas, *i.e.*, $\frac{3}{2}$ RT. In a solid, as we have seen the molecules excursions are restrained by the repulsion of their neighbours. During part of their oscillations therefore, the kinetic energy is converted into potential energy. If the restoring force is proportional to the displacement the oscillations are harmonic and it may be shown that the potential energy averaged over a long time is equal to the kinetic energy. Hence the atomic heat of a solid at constant volume, should be exactly twice that of a monatomic gas at constant volume, which latter is 3 R. This result is of course in good agreement with Dulong Petit's and Kopp's law and was at one time held to be an important confirmation of these empyrical approximations. Ordinary measurements of atomic heats of solids are of course carried out at constant pressure and not at constant volume, but a simple thermal dynamical consideration enables one to show that the difference $c_p - c_v = \frac{9\beta^2}{\kappa}T$ where β is the thermal expansion coefficient, κ the compressibility and T the temperature.

Without making too extended an incursion into that large body of hypotheses and doctrine usually grouped under the heading Quantum Theory (*q.v.*), it is impossible to give an accurate derivation of the formula which represents the atomic heat as a function of the temperature. Roughly, one may summarize the quantum condition by saying that the oscillating system at any given time can only be in one of a number of discrete states, these states corresponding to energy levels, differing from one another by one quantum of energy. If the classical statistical mechanics were true, every energy level would be possible and the probability of any one corresponding to an energy ϵ would be given by $e^{-\epsilon/kT}$, k being Boltzmann's constant and T the temperature. The sum of all the energies of N molecules each having three degrees of freedom would thus be $U=3NkT=3RT$ for one gramme molecule. With the quantum restriction a system of oscillating particles will contain less energy, for the energy which on the classical view would be contained by molecules having less than one quantum ϵ, would not be present, similarly all the molecules which on the classical view would contain energies between one and two quanta, would only have one quantum, and again those molecules which should contain between two and three quanta, would have exactly two quanta. Hence the total energy instead of being given by the above expression is equal to

$$\begin{aligned} U &= 3N\left[\epsilon(e^{-\epsilon/kT}-e^{-2\epsilon/kT})+2\epsilon(e^{-2\epsilon/kT}-e^{-3\epsilon/kT})+\cdots\right] \\ &= 3N\epsilon\left[e^{-\epsilon/kT}+e^{-2\epsilon/kT}+e^{-3\epsilon/kT}+\cdots\right] = \frac{3N\epsilon}{e^{\epsilon/kT}-1}\cdots \end{aligned}$$

This formula shows that the atomic heat of a solid

$$\frac{dU}{dT} = 3R\frac{\left(\frac{\epsilon}{kT}\right)^2 e^{\epsilon/kT}}{(e^{\epsilon/kT}-1)^2}$$

reaches a value $3R$ asymptotically at temperatures high compared to ϵ/k but that it falls far below this value and indeed to zero at low temperatures. It is clear that if the quantum ϵ becomes zero one arrives at the classical result; it is its finite value which leads to the discrepancy. One of the most fundamental requirements of the quantum theory is that the quantum is proportional to the frequency ν *i.e.*, $\epsilon = h\nu$. Hence elements with high proper frequencies have large quanta, and elements with low frequencies small quanta. But as we have seen high proper frequencies are characteristic of elements which combine a large restoring force with a small atomic weight. Hence deviations from the classical value for the atomic heat, *i.e.*, Dulong Petit's law, are to be expected at comparatively high temperatures in elements such as carbon or boron, which combine small compressibility or high melting point with low atomic weight. On the other hand elements of high atomic weight, which are soft and have low melting points, such as lead or mercury, have a low frequency, *i.e.*, they obey Dulong Petit's law down to very low temperatures. That carbon and boron deviated from the normal was known to Dulong Petit, but it is only within the last 20 years that the explanation has been found.

The above formula can only be correct if all the particles have the same proper frequency. As was mentioned above, this is not the case since a large number of lower frequencies can also occur. Strictly speaking therefore, one should substitute for the above formula an expression of the form $\int f(\nu)\frac{3Nh\nu}{e^{h\nu/kT}-1}d\nu$ when $f(\nu)d\nu$

represents the probability of a frequency between ν and $\nu+d\nu$. The calculation of this probability is extremely complex and depends of course upon the assumptions made about the lattice and the intermolecular forces. It has been carried out in a number of the more straightforward cases by Born, but the expressions are in general too complicated to be of practical use.

A simpler line of attack was developed by Debye. The slow frequencies really are nothing but the harmonics upon the fundamental frequency, *i.e.*, the fundamental note of the solid. Each mode of vibration may be regarded as a stationary wave and the probability of any given frequency merely corresponds, on this view, to the number of ways in which one can arrange stationary waves of a given wave length in a solid. This number is obviously proportional to $\sqrt{(p^2+q^2+r^2)}$ where p, q and r are whole numbers, hence the probability is proportional to the number of ways in which one can arrange a set of whole numbers so that the sum of their squares lies between given limits. It may readily be shown that this is proportional to the square of the frequency so that the probability function, according to Debye, may simply be written $f(\nu) \propto \nu^2$. This derivation is of course accurate only for long waves and breaks down for the more numerous higher frequencies. Nevertheless, to facilitate computation and avoid complication Debye extended this formula right up to the higher frequencies, determining his constant by the condition that the sum of all probabilities must be equal to one, *i.e.*, the total of all the modes of vibration must amount to the total number of degrees of freedom, $3N$. Thus he gave for the final formula for the atomic heats $\frac{d}{dT}\left(3RT\frac{3}{x}\int_0^x \frac{\xi^3 d\xi}{e^\xi - 1}\right)$ where x is θ/T, $\theta = \frac{h\nu_m}{k}$ being the quantity he termed a characteristic temperature and ν_m the maximum frequency being defined by $\int_0^{\nu_m} f(\nu)d\nu = 1$.

These formulae of course only apply to monatomic substances. When one is dealing with substances in which the atoms are combined in molecules, much more complicated conditions prevail. Strictly speaking all these problems could be attacked by the method developed by Born, but this requires a knowledge of the chemical forces as well as the cohesive force. This knowledge is at present almost entirely lacking but for practical purposes the method adopted by Nernst is adequate. He assumed that in a crystalline compound the molecules could be treated as forming a space-lattice and their contribution to the heat capacity expressed by Debye's formula. The oscillations of the atoms in the molecule he regarded as being little affected by the neighbouring molecules and therefore applied to them Einstein's formula which corresponds to a line spectrum. By this means he was able to represent with great fidelity the molecular heats of various compounds. The large deviations found from Kopp's law are readily explained on this view; for the atomic frequencies under the comparatively large restoring forces inside the molecule, are often very high and their contribution to the specific heats, even at comparatively high temperatures, may be well below the classical value.

Like practically all substances, solids expand on heating. Their thermal expansion, however, is smaller than that of liquids and far less than that of gases. This is intelligible in view of the picture of their constitution which has been outlined. In a space-lattice formed of molecules held in place by their mutual attractions and repulsions, the primary effect of increasing the temperature is to increase the kinetic energy and consequently the amplitude of oscillation of the particles. If the restoring force is strictly proportional to the displacement, *i.e.*, if the oscillations are strictly harmonic, there will be no tendency to expand, for the molecules will remain equally long at either extremity of their swing and exert equal forces of attraction and repulsion upon their neighbours. This condition is of course not strictly possible in reality, for it leaves out of account the conditions at the surface. Here at any rate there must be asymmetrical oscillations in which the molecules on their inward incursions are repelled by their neighbours, but on their outward swings are limited by the attraction of these same neighbouring molecules. As has been said, it is this very attraction which gives rise to the internal pressure in solids. It is clear that this same internal pressure limits the volume since this is determined by equating the total excess outward pressure of the oscillating particles to their mutual attractions. As has been shown, to a first approximation, the curve representing the force between the molecules near their positions of equilibrium, can be treated as a straight line, in other words a given deviation gives rise to just as much attraction from one side as repulsion from the other. This however is only a first approximation. Strictly speaking, the repulsion increases more rapidly than the attraction, otherwise the substance would not be stable and would collapse. Therefore any increase in the amplitude of the oscillations must give rise to an outward force equal to the aggregate of these differences which will lead to a general expansion of the solid. As has been stated, of course this is only a second order effect due to the nonlinearity of the function representing the restoring force, *i.e.*, to the fact that the restoring force is not strictly elastic. If it were, that is to say if Hooke's law were strictly true and the extension of a solid were accurately proportional to the applied force, there would be no tendency to expand on heating. The extension which is observed, is due to and indeed a measure of this small deviation from the perfect elastic properties which an idealized solid would possess and real solids at low temperatures approach. This being so it is plain that the expansion coefficient will vary with the temperature. At sufficiently low temperatures where the amplitude of oscillation is small the thermal expansion diminishes and approaches zero as the absolute zero is reached. To a first approximation it is proportional to the atomic heat.

Another property of solids, whose relation to this same phenomenon was formerly not recognized, is the thermal conductivity. All solids conduct heat to a greater or less degree, their conductivity being measured by the amount of heat which flows through unit cross-section in unit time under the influence of unit temperature gradient. There are, however, two classes whose conductivity differs considerably, the metals and the non-metals. The metals in general conduct very much better than the non-metals; the mechanism of their thermal conduction however is almost certainly of a different type being due to the dissociated electrons which give to them their specific property of electrical conductivity. The non-metals conduct in a varying degree, some of them such as the precious stones, more especially the diamond conducting extremely well, whilst others such as glass or mica have a conductivity very much smaller. The reason for this is intelligible, when one considers the model we have described. If one had completely elastic substances obeying Hooke's law accurately, the heat conductivity, as measured in the ordinary way, would be infinite, for heat in the form of elastic waves would be propagated from one end to the other with the speed of sound, and in equilibrium no temperature gradient could exist. At first sight this may seem paradoxical since a perfect vacuum in which heat is transmitted by radiation, which for this purpose may be regarded as harmonic waves, is usually considered to be a bad conductor. Nevertheless if its conductivity were measured in the ordinary way, it would be found to be infinite, since the amount of heat transmitted is independent of the temperature gradient and the fact that it is small is a consequence not of bad conductivity, but because only a comparatively small amount of heat can be transferred from the solid wall to the vacuum. The fact that solids have a finite heat conductivity is due to their elastic properties not being strictly linear. Thus an elastic wave passing over a region in which there happens to be, say, a small excess compression due to another elastic wave is slightly scattered, since owing to the compression already existing and the lack of the linearity of the compressibility, this latter is slightly reduced and the velocity of propagation slightly increased. Hence in traversing the solid, the waves are scattered and a certain proportion returns instead of going for-

ward. If one defines a length l in which the elastic wave amplitude is reduced by scattering to $\frac{1}{e^{th}}$, it may be shown that the thermal conductivity will be given by $\frac{\rho qsl}{4}$, ρ being the density, q the velocity of propagation of the wave and s the specific heat.

This consideration shows that there will be an essential difference between the heat conductivity of crystals and amorphous solids. A crystal, until one comes down to molecular dimensions, may be regarded at the absolute zero as a completely homogeneous body. As the temperature rises owing to the random distribution of energy, there will be regions of excess strain and the reverse. If the forces were strictly elastic this would not affect the velocity of propagation of compressional or torsional waves. But the forces are not strictly elastic, consequently as the temperature is raised the scattering of the elastic waves increases. Hence, as shown by the above expression, the thermal conductivity should decrease with rising temperature; calculation shows that in the region in which the specific heat is constant, it should be inversely proportional to the absolute temperature. This result was confirmed by measurements of the thermal conductivity of crystals at different temperatures.

The amorphous solids behave quite differently. In these, as we have seen, the molecules do not form a space-lattice, but may be regarded as distributed more or less evenly, without being in any special regular order. In glasses therefore, there are inhomogeneities of density and compressibility which are inherent in the structure itself, neither due to nor affected by the temperature. The elastic waves, therefore, will be scattered in an amorphous body even at the absolute zero, indeed an increase in temperature is just as likely to improve as to diminish the homogeneity of such a substance. Hence there should be no variation in thermal conductivity with temperature due to modification in scattering; any variation which occurs must be attributed to a change in the specific heat, in general a much less important factor. Thus the heat conductivity of glasses is not very much affected by temperature.

The metals as has been stated, form a class apart. In these, electrons are dissociated from the atoms and play a large part in conduction, as is shown by the proportionality of thermal and electrical conductivity. If one assumes that the electrons form an interleaved space-lattice with the parent ions, then, owing to their small mass, they would have a very high proper frequency. Such an electron space-lattice might thus be regarded, as far as thermal properties are concerned as corresponding to a crystal at a very low temperature. From this point of view, the high thermal conductivity of metals is intelligible, but it is a point of view which has certain difficulties and is not fully established.

We have seen that the properties characteristic of the solid state may all be explained on the assumption that the forces acting between the molecules are of the type indicated by the curve in figure 1. The definite volume of the solid is due to the rapid increase of the force of repulsion when the atoms approach one another. Its density is determined by the molecular weight and the distance at which repulsion balances attraction. The shape of the solid is determined by the quasi-elastic forces arising when molecules are displaced from their positions of equilibrium and these forces are merely another expression of the intramolecular forces holding the molecules in place. Crystals are solids in which the attractive forces have been given full play and the molecules have attained the closest packed order. Glasses are merely under-cooled liquids in which the viscosity is too high to permit crystallization to take place. The melting point is that temperature at which the oscillations of the molecules are so great as to cause them to collide; the latent heat is at any rate in part the work done against attraction when they expand on fusion.

Hooke's law expresses the fact that the law of force is approximately linear near the position of equilibrium. Deviations from it account for the thermal expansion and determine the heat conductivity. The variation of the atomic heat with temperature depends according to the very much more recondite quantum theory upon the molecular frequency; this is obviously determined merely by the molecular restoring force and the molecular weight. Thus substances with large intramolecular forces and small atomic weights such as occur in the middle columns of the periodic table, will be hard and incompressible with high melting points and latent heats, with small thermal expansion coefficients, but great thermal conductivities and their atomic heats will deviate even at high temperatures from the normal value. Where the intramolecular forces are small, more especially if the atomic weights are high, we have soft compressible, low melting solids with large expansion coefficients and small heat conductivity. Owing to the dissociation of the electrons, metals are in another category whose special characteristics lie outside the scope of this article. The same may be said of those other properties, whether optical or electrical, magnetic or radioactive which solids possess in common with matter in other states of aggregation. (F. A. L.)

SOLIMAN I.,[1] the "Magnificent" (1494–1566), sultan of Turkey, succeeded his father Selim I. in 1520. His birth coincided with the opening year of the 10th century of Mussulman chronology (A.H. 900), the most glorious period in the history of Islam. Though in Turkey he is distinguished only as the lawgiver (*kanuni*), in European history he is known by such titles as the Magnificent. He was the most fortunate of the sultans. He had no rival worthy of the name. From his father he inherited a well-organized country, a disciplined army and a full treasury. He united in his person the best qualities of his predecessors, and possessed the gift of taking full advantage of the talents of the able generals, admirals and viziers who illustrated his reign. If his campaigns were not always so wisely and prudently planned as those of some of his predecessors, they were in the main eminently fortunate, and resulted in adding to his dominions Belgrade, Budapest, Temesvar, Rhodes, Tabriz, Baghdad, Nakshivan and Rivan, Aden and Algiers, and in his days Turkey attained the culminating point of her glory.

The alliance concluded by him with France reveals him as superior to the narrow prejudices of his race and faith, which rejected with scorn any union with the unbeliever, and as gifted with political insight to appreciate the advantage of combining with Francis I. against Charles V. His Persian campaign was doubtless an error, but was due in part to a desire to find occupation, distant if possible, for his janissaries, who were always prone to turbulence while inactive at the capital. He was perhaps wanting in firmness of character, and the undue influence exercised over him by unscrupulous ministers, or by the seductions of fairer but no less ambitious votaries of statecraft, led him to make fatal concessions. It is from Soliman's time that historians date the rise of that occult influence of the harem which has so often thwarted the best efforts of Turkey's most enlightened statesmen.

Soliman's claims to renown as a legislator rest mainly on his organization of the Ulema, or clerical class, in its hierarchical order from the Sheikh-ul-Islam downwards. He reformed and improved the administration of the country both civil and military, inaugurated a new and improved system for the feudal tenures of limitary fiefs, and his amelioration of the lot of his Christian subjects is not his least title to fame. He wrote verses under the pseudonym of "Muhibbr." (*See* Hammer-Purgstall, *Gesch. d. Osman. Reichs*, ii. 331; and further TURKEY: *History*.)

Soliman died on Sept. 5, 1566, at the age of 72, while conducting the siege of Szigetvār.

SOLIMAN II. (1641–1691), sultan of Turkey, was a son of Sultan Ibrahim, and succeeded his brother Mohammed IV. in 1687. Forty-six years of enforced retirement had qualified him for the cloister rather than for the throne, and his first feeling when notified of his accession was one of terror for his brother's vengeance. Nor were the circumstances following on his elevation to the throne of a nature to reassure him, as one of the most

[1] Soliman, eldest son of Bayazid I., who maintained himself as sultan at Adrianople from 1402 to 1410, is not reckoned as legitimate by the Ottoman historiographers, who reckon Soliman the Magnificent as the first of the name. By others, however, the latter is sometimes styled Soliman II.

violent of the revolts of the janissaries ended in the murder of the grand vizier and the brutal mutilation of his family, with general massacre and pillage throughout Constantinople. The war with Austria was for Turkey a succession of disasters. At this time, fortunately for the Ottoman empire, a third great Kuprili (Mustafa) arose and re-established order in the sorely-tried State. (*See* KUPRILI.) In the reforms which followed, whereby the situation of the Christian subjects of the Porte was greatly improved, Soliman is at least to be given the credit of having allowed Mustafa Kuprili a free hand. With an improved administration Turkey's fortunes in the war began to revive, and the reconquest of Belgrade late in 1690 was the last important event before Soliman's death in 1691. (*See* also TURKEY: *History*.)

SOLINGEN, a town in the Prussian Rhine Province, on a height above the Wupper, 13 m. E. of Düsseldorf, and 20 m. N.E. of Cologne by rail. Pop. (1925) 52,002. Sword-blades have been made here since the early middle ages, and tradition affirms that the art was introduced during the Crusades by smiths from Damascus. Solingen is one of the chief seats of the German iron and steel industry, its speciality consisting in all kinds of cutlery, knives, razors, scissors, files, steel frames and the like, produced in enormous quantities. Other metal wares are also manufactured. These articles are largely made by the workmen at their own homes and supplied to the dépôts of the large dealers. Solingen received its municipal charter in 1374.

SOLINUS, GAIUS IULIUS, Latin grammarian and compiler, probably flourished during the first half of the 3rd century A.D. He was the author of *Collectanea rerum memorabilium*, a description of curiosities in a chorographical framework. Adventus, to whom it is dedicated, is identified with Oclatinius Adventus, consul A.D. 218. It contains a short description of the ancient world, with remarks on historical, social, religious and natural history questions. The *Collectanea* was revised in the 6th century under the title of *Polyhistor* (subsequently taken for the author's name). It was popular in the middle ages, hexameter abridgments being current under the names of Theodericus and Petrus Diaconus.

The commentary by Saumaise in his *Plinianae exercitationes* (1689) is indispensable; best edition by Mommsen (1895), with valuable introduction on the mss., the authorities used by Solinus, and subsequent compilers. *See* also Teuffel, *Hist. of Roman Literature* (Eng. trans., 1900), 389; and Schanz, *Geschichte der römischen Litteratur* (1904), iv. 1. There is an old English translation by A. Golding (1587).

SOLIPSISM, a philosophical term, applied to an extreme form of subjective idealism which denies that the human mind has any valid ground for believing in the existence of anything but itself (Lat. *solus*, alone, *ipse*, self). "It may best be defined, perhaps, as the doctrine that all existence is experience, and that there is only one experient. The Solipsist thinks that *he is the one!*" (Schiller). It is presented as a solution of the problem of explaining the nature of our knowledge of the external world. We cannot know things-in-themselves: they exist for us only in our cognition of them, through the medium of sense-given data. In F. H. Bradley's words (*Appearance and Reality*): "I cannot transcend experience, and experience is *my* experience. From this it follows that nothing beyond myself exists; for what is experience is its (the self's) states." Solipsism is now mostly regarded, for example, by Bertrand Russell, as a *reductio ad absurdum* of subjective idealism.

See IDEALISM.

SOLITAIRE (*Pezophaps solitarius*), an extinct bird allied to the dodo (*q.v.*) and formerly inhabiting Rodriguez. It became extinct about 1761. The male stood about 2ft. 9in. high and was brownish grey in colour, the female being brown with a whitish breast. The male bore a knob of bone on each wing, and used this as a weapon. Like the dodo, the solitaire was flightless.

Of the New World solitaires, related to the thrushes, the melodious Townsend solitaire of the Rockies is the best known.

SOLOGNE, a region of France extending over portions of the department of Loiret, Loir-et-Cher and Cher. Area 1,800 sq. miles. Its boundaries are, on the north the Loire, on the south the Cher, on the east the districts of Sancerre and Berry. The Sologne is watered by the Cosson and the Beuvron, tributaries of the Loire, and the Sauldre, an affluent of the Cher, all three having a west-south-westerly direction. The impermeable mixture of sand and clay has given rise to numberless pools and marshes; portions were being drained largely by Huguenots, when persecution scattered them and the work was delayed until Napoleon III. led the way in the reclamation of swamps, the planting of pines and other trees and other improvements. These changes have much improved the climate of the district. Arable farming and stock-raising are flourishing in the Sologne, but there is little manufacturing activity, the cloth manufacture of Romorantin being the chief industry. Game is abundant, and the region owes much of its revived prosperity to the creation of large sporting estates; it was a hunting country centuries ago.

SOLOGUB, FEDOR, pen name of Fedor Kuzmich Teternikov (1863–1927), Russian man of letters, was born on Feb. 17, 1863 in St. Petersburg (Leningrad), the son of a tailor. He died on Dec. 6, 1927. On the latter's death, his mother became a domestic servant and the son was brought up by her employers. He studied at the Teachers' Institute in St. Petersburg and was a schoolmaster for 25 years, retiring in 1907. In 1897 he published his first volume of poetry and also some short stories. He is considered the greatest figure of the Symbolists in prose and poetry. His best novel is *The Little Demon* (1907), in which he has created a universal type of evil in the central figure, the schoolmaster, Peredonov. He also wrote several plays.

His other works include *The Sorcery of Death* (a series composed of *The Created Legend, Drops of Blood, Queen Ortruda*, and *Smoke and Ashes*). *The Little Demon, The Created Legend, The Old House and other Tales* have been translated into English.

SOLOLÁ, the capital of the department of Sololá, in Guatemala; near the northern shore of lake Atitlán, 46 m. W.N.W. of Guatemala city. Pop. (1925) 17,334. Sololá is the ancient capital of the Cakchiquel Indians, who form the bulk of the population. In the city coarse cloth, pottery, cigars and soap are manufactured, and there is a large prison and reformatory. Among the surrounding mountains are large and successful coffee plantations, some owned by German settlers. On April 18, 1902 Sololá was wrecked by an earthquake, but as most of the houses were constructed of wood it was speedily rebuilt.

SOLOMON, son of David, succeeded his father on the throne of Israel *c.* 974 and reigned until *c.* 937. In the story of David's intrigue with Bathsheba (2 Samuel xi.–xii. 25) Solomon is the second child of the union, born after David had made her his wife, and after the death of the illegitimate child. But in the lists of David's children, 2 Samuel v. 14, 1 Chronicles iii. 5, xiv. 4, he seems to be the fifth child of the union, a discrepancy indicative of the uncertainty attaching to many particulars of his history. The name *Solomon* may mean "peaceful"; according to 1 Chron. xxii. 6–19, David was directed by Yahweh so to name his son as symbolizing the "peace and quietness" which, in contrast to the turbulence of his own reign, should be the characteristics of Solomon's. A variant reading in 2 Sam. xii. 24, however, states that Bathsheba herself chose the name, which is not improbable, for other instances are found in the Old Testament where the mother, not the father, names a child. The following verse says that the prophet Nathan gave to the child the name Jedidiah, "beloved of Yahweh," the first element in which is from a root akin to *David*. This name is found nowhere else, and presumably never came into common use.

The Accession.—In contrast to the summary notices given in the books of Kings to the beginning of a new reign the circumstances of Solomon's accession are related with very full detail. To call Solomon "not the true heir to the throne" is mistaken, for in the case of a monarchy such as that of Israel there was no rule that the king's eldest son was his legitimate successor; the king might nominate any one of his sons to take his place: yet it is probable that Solomon had not been regarded as the son most likely to succeed David. The eldest son, Amnon, had been slain by Absalom, the third son, who was himself killed in an abortive revolt against his father. Of the intermediate son, Chileab, nothing is known.

When David was evidently on the point of death his son Adonijah, who "was born after Absalom," set to work to ensure for himself the right of succession. Like Absalom he was a man of fine appearance, and seemingly popular. He appears also to have been a favourite with his father (1 Kings i. 6). He surrounded himself with a royal bodyguard, and enlisted the aid of the two foremost men in David's court, the warrior Joab and the priest Abiathar. At a feast he prepared he seems to have received support from the men of Judah and most of the king's sons, but his deliberate exclusion of the prophet Nathan, the warrior Benaiah, the "mighty men," and Solomon, from the invitation would suggest that the question of the succession had already been the subject of palace intrigue, and that there was a "pro-Solomon" party.

At Nathan's instigation Bathsheba reminded the feeble old king of an oath he had sworn to make Solomon his successor, which story the prophet came in and confirmed. Whether this was really the case or not—on one view of the narrative it would seem that David in his weakness was persuaded that he had made such a promise—the king immediately caused Nathan, Benaiah and Zadok the priest, to proclaim Solomon. This action met with approval on the part of the citizens, and Adonijah's party, rather surprisingly, collapsed without a struggle, he himself seeking asylum at the altar, and being sentenced to confinement in his own house.

Subsequently Joab was killed by Benaiah, and Abiathar replaced by Zadok, at Solomon's command, Adonijah having been previously slain for preferring a request that Abishag, the damsel who had cherished David in his last days, should be given to him as wife. This would, according to Oriental ideas, have been equivalent to claiming the succession, and it is indeed difficult to believe the story that Adonijah made such a request through Bathsheba. It is possible that this narrative, and also the instruction given by David to Solomon that Joab should be slain, are invented to palliate the ruthlessness with which Solomon removed from his path those who had challenged his position.

The King.—The general impression which the Biblical narratives seek to convey is that Solomon's reign was most prosperous and peaceful. Nor can it be denied that this impression has substantial evidence in its favour. To take one simple point, the fact that the reign of Solomon endured for forty years shows that he must have consolidated firmly the kingdom he inherited, though he had no great love for military adventure and made no attempt to enlarge its borders. Rather he sought to make his position secure by allying himself with his more considerable neighbours. Early in his reign he ensured the friendship of Egypt by espousing the Pharaoh's daughter. This alliance brought about also a further gain, for the Pharaoh, who had attacked and reduced the important Canaanite fortress Gezer, handed it over to Solomon as a dowry for his daughter, and Solomon rebuilt it. Perhaps even more advantageous was the extension of the alliance which David had earlier concluded with Hiram, the ruler of Tyre. This afforded Solomon security on his northern frontier, and enabled him to use freely the Mediterranean Sea. The erection of high places near Jerusalem for the worship of the deities of Zidon, Moab, and Ammon (2 Kings xxiii. 13) is indicative of friendly relations with those peoples. That he was able to use a port at the head of the Gulf of Akaba (1 Kings ix. 26) for commerce with Ophir implies that Solomon controlled Edomite territory on his southeast border.

The commercial activity of Solomon seems to have been extensive. In this respect he reminds us of the Pharaohs, who appear almost to have monopolized the foreign commerce of Egypt. His imports were on a scale so lavish that he is said to have made silver as common as stones, cedars as sycamores, in Jerusalem. There was an extensive trade in horses (1 Kings x. 27–29). In partnership with Hiram of Tyre he maintained a fleet of ocean-going ships trading at regular intervals to Mediterranean ports, bringing "gold, silver, ivory, apes and peacocks" (1 Kings x. 22). In his trading ventures down the Gulf of Akaba he was assisted by skilled Tyrian navigators supplied by Hiram (1 Kings ix. 27–28)—his own people never did take kindly to the sea. This passage was evidently misunderstood by the Chronicler, who took it to mean that Hiram supplied the ships (2 Chronicles viii. 18): how they were transported is a problem he leaves unexplained. Ophir, the land to which these vessels ventured is not identified with certainty, but may be S. Arabia. Solomon brought Israel for the first time fully into the current of oriental commerce and civilization, and during his reign Jerusalem, at any rate, was a city of wealth and luxury.

The Builder.—The long and peaceful reign of Solomon permitted him to indulge his passion for building, and his activities completely transformed his capital city, Jerusalem. David had built a palace there, being furnished with artificers and material by Hiram. This was, however, not regarded by Solomon as sufficiently splendid, and he spent thirteen years in constructing a magnificent royal dwelling. He built also a temple, the details of which occupy a disproportionate space in the records, for it was, after all, in the nature of an appanage to the palace, and took little more than half the time devoted to the latter. Like his father, he relied largely upon Hiram for material and artisans. Round his new buildings he erected a wall. He also built and fortified numerous cities which were used as barracks, arsenals and storehouses.

In order to obtain supplies for his grandiose schemes he divided the land into twelve districts, seemingly independent of the old tribal divisions, upon which levies were made in rotation. Forced labour was exacted from the Canaanites. But though the boast is made that the Israelites were not treated as "bond-servants," the exactions made from them for the upkeep of the costly court and harem, and the expenses of building, must have reduced many of the poorer people to a condition hard to distinguish from slavery. However splendid the court and capital may have been, the state of the ordinary folk must have been far from happy, and in the lavish expenditure of Solomon may be found a prime cause of the discontent which led under his successor to the division of the kingdom.

Factors of Unrest.—Nor was the political situation quite as easy as the picture in Kings might lead us to suppose. The exact interpretation of 1 Kings ix. 12–14 is uncertain, but evidently Solomon was compelled to part with territory in the north to placate Hiram. An Edomite, Hadad, who had escaped the ruthless slaughter of Edomites by Joab under David, took refuge at the Egyptian court, where he attained a considerable position. He returned to his native country after the death of Joab, and evidently was a thorn in Solomon's side (1 Kings xi. 25). Rezon, an Aramean, too, established himself in Damascus, and was "an adversary to Israel all the days of Solomon." And, though the attempt of the able Jeroboam at revolt was crushed by the king so that he was compelled to seek asylum in Egypt, he had established a sufficient personal ascendancy to gain the allegiance of the northern tribes after Solomon's death. Undoubtedly the shadows have been toned down in the Old Testament records of Solomon's reign. This does not, however, prevent us from recognizing that he was, with all his limitations, an able ruler. Though very little of the "wisdom" which is attributed to him in the Old Testament is correctly assigned, it is extremely unlikely that the attribution would have been made had not the facts of his rulership provided a basis for the picture of "Solomon the Wise."

Religion.—Solomon was a sincere worshipper of Yahweh, more cultured but less passionate in his devotion than David. His erection of altars to foreign deities for the sake of his foreign wives, and even his participation in the rites connected with them, would not be in his eyes apostasy from Yahweh. These things were of the political rather than the religious sphere. But in the eyes of later puritans they were departures from orthodoxy. So we have the curious double picture of Solomon as on the one hand a most pious benefactor to the national religion in his building of the temple and care for its ceremonial—though even here the doubt insinuates itself as to whether he did not consider to some extent the prestige which was reflected on himself; on the other hand as an apostate, who when his obituary notice is written (1 Kings xi. 43) receives no glowing testimonial, and about whom it is said that he "went not fully after Yahweh, as did David his father"

(1 Kings xi. 6). Yet even the passage which contains this censure shows that the other side of the picture was not forgotten, because it represents with more charity than truth the participation of Solomon in the rites of foreign altars as a lapse of his old age (1 Kings xi. 4).

For Mohammedan and other stories of Solomon, the queen of Sheba, etc., *see* Salzberger, *Die Salomo-Sage in der Semitischen Literatur* (1907). (W. L. W.)

SOLOMON, ODES OF, a collection of 42 hymns known to the early Christian Church. In the 6th century they appear in a list which includes most of the books in the Old Testament Apocrypha, and again in the 9th century they are placed in the Stichometry of Nicephorus between the books of Ecclesiasticus and of Esther, and bracketed with the collection of 18 so-called Psalms of Solomon, which was composed in the 1st century B.C. Both the collections are, of course, pseudonymous.

A complete manuscript of the odes was recovered in 1908 by Dr. Rendel Harris from a 16th century Syriac manuscript in his possession (which also contained the Psalms of Solomon). The version is written on paper possibly between three and four hundred years old, and came it is believed from the Valley of the Tigris, together with a miscellaneous collection of other Syriac leaves. Prior to this the only places where the text of any of these odes could be read was in the Pistis Sophia, though there is a short extract from one in the Institutes of Lactantius. In Dr. Harris's manuscript the first, second, and part of the third odes are missing, but the first has been restored from the Pistis Sophia.

This latter volume is a curious compilation purporting to record a series of conversations which took place on the Mount of Olives between the Risen Christ and his disciples in the 12th year after the Resurrection, and is interspersed with a series of hymns called Metanoiai or acts of penitence. It is believed to have been written in Egypt between A.D. 200 and 250, and to be the handbook of a Gnostic "mystery" or religious service. The occurrence in it of the five odes of Solomon is felt by some students to throw a light upon the use and object of the entire collection. They are in fact thought to be baptismal hymns, psalms of initiation into a Christian "mystery." While there are thoughts and expressions which lend themselves to Gnostic use there is nothing in the odes which is of distinctively Gnostic origin. Many of them indeed are unmistakably Christian though some may be Jewish, and the writer of the Pistis Sophia seems to have regarded them as almost if not quite canonical. Dr. Harris would date several of them between A.D. 75 and 100.

They contain few traces of the New Testament, and the words "Gospel" and "Church" are not found. Here and there a Johannine atmosphere is to be detected, but not sufficiently to justify the assumption that the author knew the Johannine literature, though the expression "the Word" occurs. References to the life and teaching of Christ are rare, though the Virgin birth is alluded to in ode 19 in a passage marked by legendary embellishment, and the descent into Hades is also mentioned several times. There are no clear allusions to baptism and none at all to the Eucharistic celebration. One passage speaks of ministers (perhaps deacons) who are entrusted with the Water of Life to hand to others. The word priest occurs once in the beginning of ode 20. "I am a priest of the Lord, and to Him I do priestly service, and to Him I offer the sacrifices of His thought."

Mgr. Batiffol argues that Solomon stands spiritually for Our Lord, and that the general doctrine of the odes is Docetic. His argument is somewhat weakened by the fact that in many of the odes the speaker appears to be a redeemed human being and not the Messiah. The odes seem to have been originally written in Greek. They vary in execution and spiritual tone, though most of them represent a very high level of spiritual experience and an intense warmth of personal devotion and great buoyancy and joy. They abound in puzzles, and there is some exceptionally striking or eccentric feature about nearly half of them.

Harnack considers that they form a Jewish *Grundschrift,* with a number of Christian interpolations; he finds in them a link between the piety and theology of the Testaments of the twelve Patriarchs and that of the Johannine Gospel and Epistles. The symbol of the wheel and also that of the letter in ode 23 resemble passages in Oriental literature, and indeed the Psalms show a strong resemblance to some of the lyric poems of Hinduism.

BIBLIOGRAPHY.—J. Rendel Harris has provided an Eng. ed. (1909; 2nd ed. 1911; 3rd ed. in co-operation with A. Mingana, 2 vols., 1916–20). *See* also a German trans. with notes by A. Ungnad and W. Staerk (1910, in Lietzmann's *Kleine Texte*); A. Harnack u. Flemming in *Texte u. Untersuchungen,* III. s. 4 (1910); J. H. Bernard, an Eng. ed. (1911); Mgr. Batiffol and J. Labourt, a French crit. ed. (1911); H. Grimme (1911); G. Diettrich (1911); G. Kittel (1914). (A. C. B.)

SOLOMON, PSALMS OF. These psalms, 18 in all, enjoyed but small consideration in the early Christian Church; for only six direct references to them are found in early Christian literature, though in the Jewish Church they must have played an important rôle; for they were used in the worship of the synagogue. They were not written by Solomon, but were subsequently ascribed to him. The fact that they do not contain a single reference to Solomon is in favour of their having been first published anonymously. On the other hand, their author (or authors) may have placed over them the superscription "Psalms of Solomon" in order to gain currency for this new collection under the shelter of a great name of the past.

Language and Date.—All modern scholars are practically agreed that the Psalms were written in Hebrew. The date can be determined from references to contemporary events. The book opens with the alarms of war (i. 2, viii. I.), in the midst of a period of great prosperity (i. 3, 4, viii. 7), but the prosperity is merely material, for from the king to the vilest of his subjects they are altogether sinful (xvii. 21, 22). The king, moreover, is no descendant of David, but has usurped his throne (xvii. 6–8). But judgment is at hand. "A mighty striker" has come from the ends of the earth (viii. 16), who when the princes of the land greeted him with words of welcome (viii. 18) seized the city (viii. 21), cast down its walls (ii. 1), polluted its altar (ii. 2), put its princes and counsellors to the sword (viii. 23), and carried away its sons and daughters captive to the west (viii. 24, xvii. 14). But the dragon who conquered Jerusalem (ii. 29), and thought himself to be more than man (ii. 32, 33), at last meets with shameful death on the shores of Egypt (ii. 30, 31).

The above allusions are easy to interpret. The usurping kings who are not descended from David are the Maccabeans. The "mighty striker" is Pompey. The princes who welcomed his approach are Aristobulus II. and Hyrcanus II. Pompey carried off princes and people to the west, and finally perished on the coast of Egypt in 48 B.C. Thus Ps. ii. was written soon after 48 B.C., while Ps. i., viii., xvii. fall between 63 and 48 B.C., for they presuppose Pompey's capture of Jerusalem, but show no knowledge of his death. Ps. v., vii., ix., xiii., xv. belong apparently to the same period, but iv. and xii. to an earlier one. On the whole Ryle and James are right in assigning 70–40 B.C. as the limits within which the psalms were written.

Authorship.—The authors were Pharisees. They divide their countrymen into two classes—"the righteous" (ii. 38–39, iii. 3–5, 7, 8) and "the sinners" (ii. 38, iii. 13, iv. 9); "the saints" (iii. 10) and "the transgressors" (iv. 11). The former are the Pharisees; the latter the Sadducees. The authors protest against the Asmonaeans (*i.e.* the Maccabees) for usurping the thrones of David and laying violent hands on the high priesthood (xvii. 5, 6, 8), and proclaim the coming of the Messiah, the true son of David (xvii. 23–25), who is to set all things right and establish the supremacy of Israel. The Messiah is to be pure from sin (xvii. 41), purge Jerusalem from the defilement of sinners and of the Gentiles (xvii. 29, 30, 36), destroy the hostile nations and extend His righteous rule over all the remaining peoples of the earth (xvii. 27, 31, 32, 34, 38). Ps. xvii., xviii. and i.–xvi. can hardly be assigned to the same authors. The hopes of the Messiah are confined to the former, and a somewhat different eschatology underlies the two works (*see* Charles, *Eschatology: Hebrew, Jewish and Christian,* pp. 220–225).

SOLOMON ISLANDS (Ger. *Salomon Inseln*), an archipelago of the Western Pacific Ocean, included in Melanesia, and forming a chain (in continuation of that of the Admiralty Islands and New Mecklenburg in the Bismarck Archipelago) from N.W. to S.E. between 154° 40′ and 162° 30′ E., 5° and 11° S., with a total land area of 17,000 sq.m.

History.—The Spanish navigator Alvaro Mendaña must be credited with the discovery of these islands in 1567, though it is doubtful whether he was actually the first European who set eyes on them. In anticipation of their natural riches he named them Islas de Salomon. The expedition surveyed the southern portion of the group and named the three large islands San Cristoval, Guadalcanal, and Ysabel.

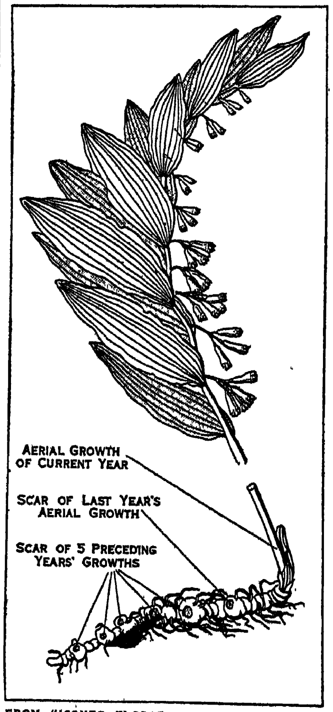
Even the position of the Solomon islands was now in uncertainty, for the Spaniards, fearful lest they should lose the benefits of the discoveries, kept secret Mendaña's narrative. The Solomon islands were thus lost sight of until, in 1767, Philip Carteret lighted on their eastern shores at Gower island and passed to the north of the group, without, however, recognizing that it formed part of the Spanish discoveries. In 1768 Louis de Bougainville found his way thither, discovered the three northern islands (Buka, Bougainville, and Choiseul), and sailed through the channel which divides the two last and bears his name. In 1769 a French navigator, M. de Surville, was the first, in spite of the hostility of the natives, to make any lengthened stay in the group. He gave some of the islands the French names they still bear, and brought home some detailed information concerning them, and their identity with Mendaña's Islas de Salomon was soon established by French geographers. In 1788 the English Lieut. Shortland coasted along the south side of the chain, and, supposing it to be a continuous land, named it New Georgia. In 1792 and 1793, d'Entrecasteaux surveyed portions of the coast-line of the large islands. Dumont d'Urville in 1838 continued the survey.

Traders and missionaries now endeavoured to settle in the islands; neither met with much success, and little was heard of the islanders save accounts of murder and plunder. In 1845 the French Marist Fathers went to Isabel, where Mgr. Epaulle, first vicar-apostolic of Melanesia, was killed by the natives soon after landing. Three years later this mission had to be abandoned; but in 1881 work was again resumed. In 1856 John Coleridge Patteson, afterwards bishop of Melanesia, had paid his first visit to the islands, and native teachers trained at the Melanesian mission college subsequently established themselves there. About this date, Benjamin Boyd, while cruising in the yacht "Wanderer," was kidnapped by the natives and never afterwards heard of. In 1873 the "foreign-labour" traffic in plantation hands for Queensland and Fiji extended its baneful influence from the New Hebrides to these islands. In 1893 the islands Malaita, Marovo, Guadalcanal, and San Cristoval with their surrounding islets were annexed by Great Britain, and a delimitation of German and British influence in the archipelago was made by the convention of Nov. 14, 1899. The German Solomon islands were occupied by an Australian force in Sept. 1914, and under mandate from the League of Nations the islands were assigned to Australia in 1920. In 1927 an outbreak of the natives, resulting in the death of several missionaries, caused the imposition of martial law.

See H. B. Guppy, *The Solomon Islands* (1887), with references to earlier works; J. Lyng, *Our New Possession,* (Melbourne, 1920).

SOLOMON'S-SEAL, the common name for perennial herbs of the genus *Polygonatum,* family Liliaceae (*q.v.*), comprising about 30 species native to north temperate regions. The plant springs from a creeping, fleshy rootstock upon which the annual shoots in dying away each year leave curious seal-like marks, whence the popular name. Three species occur in Great Britain and two in eastern North America. The single erect or arching stem, 1 to 8 ft. high, bears ovate or lance-shaped, sharp-pointed, sessile leaves in the axils of which appear narrow greenish, whitish or pinkish flowers, on slender, drooping flower stalks, followed by globular, pulpy, usually bluish berries. In the United States various species of *Smilacina,* a closely allied genus, are called false Solomon's-seal.

SOLON, Athenian statesman, the son of Execestides of the family of Codrus, was born about 638 B.C. The prodigality of his father made it necessary for Solon to maintain himself by trade, especially abroad. In his youth he became well known as the author of amatory poems and later of patriotic and didactic verse. Hence his inclusion among the Seven Sages. Solon's first public service was the recovery of Salamis from the Megarians. A law had been passed forbidding any reference to the loss of the island; Solon solved the difficulty by feigning madness, and reciting an inflammatory poem in the agora. It appears that Solon was appointed to recover the "fair island" and that he succeeded in expelling the Megarians. Sparta finally arbitrated in favour of the Athenians (*c.* 596), who ascribed their success to Solon. About a year later he seems to have moved a decree before the Amphictyons declaring war on Cirrha. At this period the distress in Attica and the accumulating discontent of the poorer classes, for whom Draco's code had proved inadequate, reached its height. Solon was summoned by all classes unanimously to discover a remedy; under the legal title of Archon, he received unlimited powers which he exercised in economic and constitutional reforms (*see* below). From various sources we learn that these reforms met with considerable opposition, to escape from which Solon left Athens for ten years. After visiting Egypt, he went to Cyprus, where Philocyprus, king of Aepea, received him with honour. Herodotus (v. 113) says that Philocyprus, on the advice of Solon, built himself a new town called, after his guest, Soli. The story that Solon visited Croesus in Lydia, and made to him the famous remark—"Call no man happy till he is dead"—is unfortunately discredited by the fact that Croesus seems to have become king nearly 30 years after Solon's legislation, whereas the story must be dated within ten years of it. Subsequently Solon returned to Athens, to find civil strife renewed, and shortly afterwards his friend (perhaps his relative) Peisistratus made himself tyrant. About 558 B.C. Solon died and, according to the story in Diogenes Laërtius i. 62 (but *see* Plutarch's *Solon,* 32), his ashes were scattered round the island of Salamis. If the story is true, it shows that he was regarded as the oecist of Salamis.



FROM "ICONES FLORAE GERMANICAE ET HELVETICAE" (BARTH)
SOLOMON'S SEAL (POLYGONATUM MULTIFLORA), A NATIVE OF EUROPE

Reforms.—The date of Solon's archonship has been usually fixed at 594 B.C. (Ol. 46, 3), a date given by Diog. Laërt. (i. 62) on the evidence of the Rhodian Sosicrates (fl. 200–128 B.C.; *see* Clinton, *Fast. Hell.* ii. 298, and Busolt, 2nd ed., ii. 259). The date 594 is confirmed by statements in the Aristotelian *Constitution of Athens* (ch. 14). For various reasons the dates 592, 591 and even 590 have been suggested by various historians (for the importance of this question *see* the concluding paragraph of this article). The historical evidence for the Solonian reforms has always been unsatisfactory. There is strong reason to conclude that in the 5th and 4th centuries there was no general tradition as to details. In settling differences there is no appeal to tradition, and this though there occur radical and insoluble contradictions. Thus the *Constitution of Athens* (ch. vi.) says that the Seisachtheia ("shaking off of burdens") consisted in a cancelling of all debts public and private, whereas Androtion, an elder contemporary, denies this specifically, and says that it consisted in the reduction of the rate of interest and the debasement of the coinage. The *Constitution* denies the existence of any connection between the coinage reform and the relief of debt-

ors. The absence of tradition is further confirmed by the fact that the *Constitution* always appeals for corroboration to Solon's *Poems*. Of the *Laws* it is probable that in the 4th century, though some dealing with agrarian distress were in existence, those embodying the Seisachtheia were not, and few if any of the purely constitutional laws remained. The main source of the account in the *Constitution* is, therefore, the *Poems* of Solon, from which numerous quotations are made (*see* chs. 5–12).

The reforms of Solon may be divided under three heads—economic, constitutional and miscellaneous. They were necessary owing mainly to the tyrannical attitude of the rich to the poorer classes. Of these many had become slaves in lieu of payment of rent and loans, and thus the land had fallen gradually into the hands of capitalists. It was necessary to readjust the economic balance and to provide against the evil of aristocratic and capitalist predominance.

A. Economic Reforms.—Solon's economic reforms consisted of the Seisachtheia and certain commercial laws (*e.g.*, prevention of export trade except in olive oil, Plut. *Solon* 24). By far the most important of these was the law encouraging trade and manufactures (Plut. *Solon,* 22) which laid the foundation of the future commercial greatness of Athens. Even within a century from the time of its making the trade of Athens with Sicily increased, as is shown by archaeological discovery in that island, to such an extent that, though negligible in quantity at the beginning of the century, it almost rivalled that of Corinth at the end of it. (*See* Grundy, *Thucydides and the History of his Age,* p. 66 ff.). Among all the problems connected with the Seisachtheia, it is clear (1) that Solon abolished the old Attic law of debt which permitted loans on the security of the debtor's person; (2) that he restored to freedom those who had been enslaved for debt; (3) that he refused the demand for the division of the land (γῆς ἀναδασμός). As to the cancelling of all debts (χρεῶν ἀποκοπή) there is some controversy; Gilbert and Busolt maintain that all debts were cancelled; strong reasons may, however, be advanced against it, amongst others, that the Greek, unlike the Roman revolutionary, though ready to deal freely with the property of others, did not seek to remedy financial difficulties by abolishing debts. It is possible that the statement in the *Constitution* is a hypothesis to explain the restoration of the slaves to freedom. Further, Solon seems to have regulated the accumulation of land (*cf.* in Rome the legislation of Tiberius Gracchus) and the rate of interest; and to have simplified commerce by replacing the Pheidonian standard by the Euboic, which was in use among the Ionian traders, in commerce with whom he foresaw that prosperity lay. It is impossible here to enter into the details of the controversy in connection with Solon's land reforms; it must suffice to give the bare outlines of the dispute. There is no question that (1) the distressed class whom Solon sought to relieve were the *Hektemoroi,* and that (2) the achievement on which he prided himself was the removal of the ὅροι or stones which were seen everywhere in Attica, and were symbolic of the slavery of the soil. Almost all writers say that these ὅροι were mortgage-pillars: that they were originally boundary stones and that when land was mortgaged the terms of the agreement were carved on the stones, as evidence. Now, firstly, though such mortgage-pillars existed in the time of Demosthenes, none are found earlier than the year 400 B.C., nor is there any reference before that year to this special sense of the word. If then these stones which Solon removed were mortgage-pillars, it is strange that none should have been found till 200 years later. Secondly, it is highly improbable that the terms on which land was then cultivated admitted of mortgaging at all. The *Hektemoroi* who, according to the *Constitution,* paid the sixth part of their produce as rent,[1] were not freeholders but tenants, and therefore, could not mortgage their land at all. From this it follows that when Solon said he had "removed the stones" he referred to the fatal accumulation of land by landowners. The tenants failed to pay rent, were enslaved, and the "boundary stone" of the landowner was moved forward to include their land. Thus the removal of the ὅροι was a measure against the accumulation of land in the form of enclosures (τεμένη), and fits in with the statement at the end of chapter iv. of the *Constitution,* "the land was in the hands of a few." It should be noted (1) that from this releasing of the land it follows that Solon's law against lending on the security of the person must have been retrospective (*i.e.,* in order to provide a sufficient number of freeholders for the land released); and (2) that it is one of the most remarkable facts in Athenian economic history that when at the end of the Peloponnesian War a proposal was brought forward to limit the franchise to freeholders, it was found that only 5,000 failed to satisfy this requirement. It is noteworthy that the *Hektemoroi* disappear from history after Solon's time. This looks as if they had been converted into freeholders. Antiquity ever tended to regard the cultivation of land as the best title to its possession, a development of an earlier idea that property in respect to land did not reside in the land itself but in the crop grown on it. The Diacrii of the time of Peisistratus are quite a different class.

[1]Others say they were: (1) labourers who received one-sixth of the produce as wages; (2) tenants who paid five-sixths as rent and kept one-sixth, or (3) tenants who paid one-sixth as rent and kept five-sixths. As to (3) it is said such tenants could not have been in real distress, and as to (1) and (2) it is said that such a position would have meant starvation from the first.

B. Constitutional Reform.—It is on this part of his work that Solon's claim to be considered a great statesman is founded. By his new constitution, he laid the foundations of the Athenian democracy and paved the way for its later developments. It should be noted in the first place that the following account is written on the assumption that the Draconian constitution described in chapter iv. of the *Constitution of Athens* had never existed (*see* DRACO). In some respects that alleged constitution is more democratic than Solon's. This, coupled with the fact that Solon is always spoken of as the founder of democracy, is one of the strongest reasons for rejecting the Draconian constitution. It will be seen that Solon's state was by no means a perfected democracy, but was in some respects rather a moderate oligarchy in which political privilege was graduated by possession of land. To Solon are generally ascribed the four classes—Pentacosiomedimni, Hippeis, Zeugitae and Thetes. Of these the first consisted of those whose land produced as many measures (*medimni*) of corn and as many measures (*metretae*) of oil and wine as together amounted to 500 measures. The Hippeis (the horsemen, *i.e.,* those who could provide a war-horse for the service of the state) were rated at over 300 and under 500 *medimni;* the third class (those who tilled their land with a yoke of oxen) at 200 *medimni* and the Thetes below 200 *medimni.* The Zeugites, probably served as heavy-armed soldiers, and the Thetes were the sailors of the state. It is likely that the Zeugites were mainly *Hektemoroi* (*see* above) whom Solon converted into freeholders. Whether Solon invented these classes is uncertain, but it seems clear that he first put them into definite relation with the political organism. The Thetes (who included probably the servants of the Eupatridae, now secured as freemen), the fishermen of the Paralia (or sea-coast), and the artisans (cerameis) of Athens for the first time received political existence by their admission to the sovereign assembly of the Ecclesia (*q.v.*). Of these classes the first alone retained the right of holding the offices of archon and treasurer; other offices were, however, opened to the second and third classes (*sc.* the Poletae, the Eleven and the Colacretae; *see* Cleisthenes [1]). It is of the utmost importance to observe that the office of Strategus (*q.v.*) is not mentioned in connection with Solon's reform. It is often said that Solon used his classification as the basis of a sliding scale of taxation. Against this, it is known that Peisistratus, whose faction was essentially the poorer classes, established a uniform 5% tax, and it is highly unlikely that he would have reversed an existing arrangement which was particularly favourable to his friends. The admission of the Thetes to the Ecclesia was an important step in the direction of democracy (for the powers which Solon gave to the Ecclesia, *see* ECCLESIA). But the greatest reform of Solon was undoubtedly the institution of the Heliaea (or courts of justice). The jury was appointed by lot from all the citizens (including the Thetes), and thus the same people elected the magistrates in the Ecclesia and subsequently tried them in the Heliaea. Hence Solon trans-

ferred the sovereign power from the areopagus and the magistrates to the citizens as a whole. Further, as the archons, at the expiry of their year of office, passed into the areopagus, the people exercised control over the personnel of that body also (*see* AREOPAGUS). In spite of the alleged Draconian constitution, alluded to above, it is still very generally held that Solon invented the Boulē or Council of Four Hundred, 100 from each of the old tribes. The importance of this body as an advisory committee of the Ecclesia, and the functions of the Prytaneis are explained under BOULĒ. It is sufficient here to point out that, according to Plutarch's *Solon,* (ch. 19) the state henceforth rested on two councils "as on anchors" and that the large powers exercised by the Cleisthenean Boulē were not exercised by the Solonian. From this and the articles AREOPAGUS, BOULĒ, ECCLESIA and GREEK LAW, it will be seen that Solon contrived an absolutely organic constitution of a "mixed" type, which had in it the seeds of the great democratic growth which reached its maturity under Pericles. It should be added here, in reference to the election of magistrates under Solon's constitution, that there is discrepancy between the *Politics* and the *Constitution;* the latter says that Solon gave to the Thetes nothing but a share in the Ecclesia and the courts of justice, and that the magistrates were elected by a combination of selection and lot (κληρωτοὶ ἐκ προκρίτων), whereas the *Politics* says that Solon gave them only the power to elect the magistrates and try them at the end of their year. It seems likely for other reasons that the former scheme should be assigned to the years after Marathon, and, therefore, that the account in the *Politics* is correct (but *see* ARCHON).

C. Miscellaneous.—The miscellaneous laws of Solon are interesting primarily as throwing light upon the social condition of Athens at the time (*see* Evelyn Abbot, *History of Greece,* I. xiii. §18). In the matter of trade it has been said that he favoured one export only, that of olive oil, in which Athens was peculiarly rich; further he encouraged the settlement of aliens (*metoikoi*) engaged in commerce, and compelled fathers to teach their sons a useful trade under penalty of losing all right to support in old age. The influence of women Solon regarded as most pernicious. Wealthy wives he forbade; no bride might bring more than three changes of raiment and a little light furniture to the house; all brothels and gymnasia were put under stringent state-control (*see* PROSTITUTION). Solon also regulated intestate succession, the marriage of heiresses, adoption, the use and sinking of wells, bee-farming, the planting of olives and figs, the cutting down of olive trees, the calendar. Further, he ordained that each citizen must show how he obtained his living (Herod. ii. 177) and must, under penalty of losing the franchise, adhere to one or other party in a sedition (for these laws *see* Plutarch's *Solon,* chs. 20–24).

The laws were inscribed on *Kyrbeis* or tablets framed in wood which could be swung round (hence also called *axones*). The boulē as a body swore to observe the laws, and each archon undertook to set up a life-size golden statue at Delphi if he should be convicted of transgressing them.

Solon appears to have supplemented his enactments by a law that they should remain in force for 100 years, and according to another account that his laws, though not the best, should stand unchanged for ten years (Plut. *Solon,* 25; *Herod.* i. 29). Yet according to the *Constitution of Athens* (chs. 11–13) (without which the period from Solon to Peisistratus was a blank), when Solon went abroad in 593 (?) the city was disturbed, and in the fifth year dissension became so acute that no archon was elected (for the chronological problem, *see* J. E. Sandys, *Constitution of Athens,* ch. 13, note); again four years later the same *anarchia* (*i.e.,* no archon elected) occurred. Then four years later the archon Damasias (582?) continued in office illegally for two years and two months. The office of the archon was then put into commission of ten: five from the Eupatrids, three from the Agroeci and two from the Demiurgi, and for 20 years the state was in a condition of strife. Thus we see that 12 years of strife (owing to Solon's financial reforms) ended in the reversal of Solon's classification by assessment. We are, therefore, driven to conclude that the practical value of his laws was due to the strong and enlightened government of Peisistratus, whose tyranny put an end to the quarrels between the Shore, the Upland and the Plain, and the *stasis* of rich and poor.

See editions with notes of *Constitution of Athens* (*q.v.*); histories of Greece later than 1891 (*e.g.,* Busolt, Eduard Meyer, etc.). *See* also Gilliard, *Quelques reformes de Solon* (1907); Cavaignac, in *Revue de Philol.,* 1908. All works anterior to the publication of the *Constitution* are so far out of date, but reference should be made to the work of Grote.
(J. M. M.; X.)

SOLOR and ALOR ISLANDS, a group of islands between Flores and Timor, an eastward extension of Flores, one of the Lesser Sunda islands, in the Dutch East Indies. They are from west to east Solor, Adunara (both small), Lomblen, Pantar and Alor (the largest). Alor, divided from Timor by Ombai passage, 17 m. wide, is very mountainous (Mt. Kolana in the east, is 6,000 ft. and Mt. Muna, in the south-west, is 4,680 ft., both old volcanoes), and is much broken up by steep ravines, with only one plateau, and some small coastal plains. It is mostly covered with low trees and *alang alang* grass. The coast is mostly rocky, with few indentations, but on the west coast, Kalabahi bay, 10 m. long and nearly a mile wide, divides a north-western promontory from the rest of the island, with which it is connected by a very low alluvial isthmus about 2½ m. wide. Pantar is high (Mt. Laki in the south is 4,450 ft.), with a rugged coast; Lomblen has mountains in the north and south (Mt. Kedang in the north-east is 4,979 ft. and Mt. Lamahero in the south is 3,350 ft.), one of which Lobetola (5,400 ft.) is an active volcano; Adunara has a volcano, Ili Buleng (5,446 ft.), in the south-east and a plateau, ringed with hills, reaching 3,000 ft.; Solor is hilly also. All the islands are attached, administratively, to the residency of Timor and Dependencies. Alor (including Pantar) has a *Gezaghebber;* the other islands come under the *Controleur* of East Flores. Alor has a population of about 50,000, resembling the natives of Timor, a warlike race of strong physique, suspicious of strangers, fond of hunting and fishing (bow and arrow the chief weapon) and leaving agriculture to the women and children, but direct Dutch rule is curbing the warlike spirit. Villages, in the hills, are in well-nigh inaccessible positions, with strong bamboo fences, the houses being on piles, and solidly built; houses on the coast are better built. Most of the people are pagans (some Mohammedans live in the north-west), the mountain folk being divided into tribes, worshipping animals (snakes and crocodiles), observing *pomali* (Tabu), growing rice, maize, tobacco, fruit and vegetables, and keeping pigs. Clothing, except at places along the coast, is very primitive. The coastal folk weave sarongs. Many tongues are spoken, differing greatly. Pantar has about 8,000 people, in the northern part of the island, pagans, tall and strongly-built, with Mohammedans on the coast. Conditions of life, etc., resemble those of Alor, but Pantar is poor, and the people often emigrate to Timor. Houses and villages are scattered and unfenced. As in Alor, many languages are spoken, one an Alorese. The population of Lomblen, Adunara and Solor is estimated at 70,000, the people being Malayo-Papuan (Wallace terms them "of dark Papuan type"), with dark skin, curly hair and strong frame. Agriculture and fishing are practised; many coco-nut trees are found on Lomblen and Adunara; the Lomblen folk weave sarongs and build boats, and all three islands have smiths. Horses, buffaloes and chickens are kept. In coastal villages houses are on the steep hill-side, almost overhanging the water. Inland villages are larger and grouped about a square, in which stands a large tree, and sometimes a round platform, where feasts are celebrated. Under European influence the defensive method of village- and house-planning tends to disappear, houses being built on flat ground. Each village has its barns and *pomali* house. Stone-carved seats for graves are known, also stone offering-places. The Adunara people prize very greatly elephants' teeth, imported, in earlier days, from Further India. Marriage is by dowry, the woman having no freedom of choice, and young girls are so highly prized that kidnapping is known on Lomblen and Adunara. The standard of married morality is high. In one part of Lomblen, some time after burial, the head is dug up and preserved in a shed. The languages spoken vary considerably from those of Alor. There is communication with Dilly, in Portuguese Timor, and with Flores and Macassar, by

vessels of the Royal Packet Navigation company, calling at Kalabahi, in Alor and at Waiwerang, in Adunara. A Portuguese claim to Larantuka, in East Flores, and the Solor islands, led the Dutch, in 1757, when there was a fear lest the Portuguese should cede Larantuka to the French, to send an agent to Solor to acquire the island for the Dutch East India company, but Portuguese claims to both Solor and Adunara were not given up until 1848, when a Dutch agent was sent to Lawajong, in Solor, to recruit labour, and the treaty between Holland and Portugal by which Larantuka, Solor, Adunara, Alor and Pantar, were surrendered was not ratified until 1859, though Dutch garrisons were placed in Larantuka and Lawajong in 1851. Disturbances at Lawajong in 1889 compelled the Dutch official there to withdraw to Larantuka, and in 1909 armed intervention in Solor became necessary, after which Solor, Adunara and Lomblen were formed into a subdivision and included in the province of the Civil Governor of East Flores. (E. E. L.)

SOLOTHURN (Fr. *Soleure*), a canton in north-west Switzerland; total area (1923–24) is 305·5 sq.m., of which 96·7% are reckoned as productive. This is higher than for any other Swiss canton. Solothurn has a most irregular shape, dependent on the fact that the canton consists of territories won at different dates by the town from which it takes its name; the whole of it, except its southern penetration into Berne, is Jura country, and it includes a great part of the river Aar, which receives the Emme near Solothurn and the Wiggern at Aarburg near Olten. It is the most irregular in shape of all the Swiss cantons, this being accounted for by the fact that it consists simply of the territories won at different dates by the town from which it takes its name. It includes most of the Aar valley between the towns of Bienne and Aarau, neither of which is in the canton, while in its northern portion the waters join the Birs River, and in its southern portion is the last bit of the Emme before its junction with the Aar. It comprises three isolated districts, of which one (Steinhof) on the south is an "enclave" in the canton of Bern, while the others, Hofstetten, that includes the famous pilgrimage resort of Mariastein, and Klein Lutzel, are on the Alsatian frontier, and bounded by the cantons of Bern and of Basel. The highest point in the canton is the Hasenmatt (4,751 ft.) summit of the Weissenstein ridge, which rises immediately north-west of the cantonal capital. Highroad and railway communications are excellent. Olten is a great railway junction where the direct lines from the St. Gotthard via Lucerne, from Geneva, from Zürich, and from Basle all unite. Formerly various districts were in the dioceses of Lausanne, Basle and Constance, but since 1814 they have all ranked as part of the diocese of Basle, with the town of Solothurn as the site of the bishop's palace. In 1920 the population was 130,617, of whom 125,183 were German speaking, 2,621 French-speaking and 2,514 Italian-speaking; 81,989 were Catholics, 47,441 Protestants and 163 Jews. The capital is Solothurn (13,550 pop. in 1925), and the only other fairly large town is Olten (12,400), both on the Aar. Between Solothurn and the small industrial town of Grenchen, to the west-south-west, lies the village of Selzach, noted for its annual passion-play. The estimated population in 1926 for the canton was 138,600.

Till about 1850 the cantonal activities were mainly agricultural and pastoral, and though these are still important, yet its density of population (433 per sq.m. in 1920, against 243 for Switzerland as a whole), is largely dependent on the variety of its manufactures, *e.g.*, watches, jewellery, shoes, cotton, motor parts and cement, particularly around Solothurn and Grenchen.

Soleure is divided into ten administrative districts with 132 communes. The cantonal Constitution dates from 1887, but was substantially revised in 1895. The *Kantonsrat*, or legislative assembly, is now elected according to the principles of proportional representation. The 130 deputies are chosen on the basis of one member for each 1,000 of the total resident population in 1920. The *Regierungsrat* or executive consists of five members. Both groups hold office for four years, but any 4,000 citizens can demand a popular vote on *Abberufung*, or recall, to decide as to whether the existing members shall continue to sit or not. In addition, the "obligatory referendum" and the "initiative" exist. By the former, since 1869, all laws and financial resolutions passed by the *Kantonsrat* must be approved by a popular vote. By the latter, since 1869, 2,000 electors can compel the legislative assembly to consider any legislative proposal. Further, since 1856, the demand of 3,000 electors is sufficient to necessitate a popular vote as to the advisability of effecting some constitutional change. The two members of the federal *Ständerat* and the seven members of the federal *Nationalrat* are also chosen by a popular vote.

SOLOTHURN (Fr. *Soleure*), the capital of the Swiss canton of that name, an ancient little town, situated on the river Aar. In 1920 it had 13,440 inhabitants, almost all German-speaking, with a small Catholic majority. A 16th-century rhyme claims for the town of Solothurn the fame of being the oldest place in "Celtis" save Trier. Certainly its name, "Salodurum," is found in Roman inscriptions and the remains of the Roman "castrum" still exist. Its position as commanding the approach to the Rhine from the south-west has led to its being more than once strongly fortified. The mediaeval town grew up round the house of secular canons founded in the 10th century in honour of St. Ursus and St. Victor by Queen Bertha, the wife of Rudolph II., king of Burgundy. The prior and canons had many rights over the town; but in 1218 it became a free imperial city, and in 1252 shook off the jurisdiction of the canons and took them under its protection. In 1295 we find it allied with Bern, and this connection is the key to its later history. In the 14th century the government of the town fell into the hands of the gilds, whose members practically filled all the public offices. Through Bern, Solothurn was drawn into association with the Swiss Confederation. An attempt to surprise it in 1382, made by the Habsburgs, was foiled, and resulted in the admittance of Solothurn in 1385 into the Swabian League and in its sharing in the Sempach War. It was included in the Sempach ordinance of 1393 and in the great treaty of 1394 by which the Habsburgs renounced their claims to all territories within the Confederation. In 1411 Solothurn sought in vain to be admitted into the Confederation, a privilege only granted to it in 1481 at the diet of Stans. It was also in the 15th century that by purchase or conquest the town acquired the main part of the territories forming the present canton. In 1529 the majority of the "communes" went over to the reformed faith, and men were sent to fight on Zwingli's side at Kappel (1531), but in 1533 the old faith regained its sway, and in 1586 Solothurn was a member of the Golden, or Borromean, League. Solothurn was the usual residence of the French ambassador from 1530 to 1797. From 1681 onwards, it had an aristocratic form of government; but this was finally broken down in 1831, Solothurn in 1832 joining the league to guarantee the maintenance of the new cantonal constitutions. Though distinctly a Roman Catholic canton, it did not join the "Sonderbund," and voted in favour of the federal constitutions of 1848 and 1874.

The position of Solothurn at the foot of the Jura and close to the navigable portion of the Aar has always made it a meeting-point of various routes. Six railway lines now branch thence. Its chief building is the minster of SS. Ursus and Victor, which dates from the 18th century, though it stands on the site of a far older edifice. Since 1828 it has been the cathedral church of the bishop of Basel. The ancient clock tower and the older portions of the town-hall date still further back. The early 17th century arsenal contains the finest collection of armour and old weapons in Switzerland, while the modern museum houses a splendid collection of fossils from the Jura, rocks collected by F. J. Hugi (1796–1855), a native of Soleure, and a Madonna by the younger Holbein. The building now used as the cantonal school was the residence of the French ambassadors to the Swiss confederation from 1530 to 1797. There are some fine 16th century fountains in the town, which in its older portions still keeps much of its mediaeval aspect, though in the modern suburbs and in the neighbouring villages there is a certain amount of industrial activity (watch-making, motor manufactures, etc.). One mile N. of the town is the Hermitage of St. Verena, in a striking rock gorge, above which rises the Weissenstein ridge.

See K. Meisterhaus, *Kurze Entwicklungsgeschichte der Stadt Solothurn* (1895).

SOLOVIEV, SERGEI MIKHAILOVICH (1820–1879), Russian historian, was born in Moscow on May 17, 1820, and died on Oct. 16, 1879. From 1842–44 he travelled in Europe as tutor in Count Stroganov's family. He wrote treatises on *The Relations between Novgorod and the Grand Princes* (1845), and on the *History of the Relations among the Russian Princes and the House of Rurik* (1847), and was appointed professor of history at and later rector of the university of Moscow. His *History of Russia* (29 vols.; Moscow, 1851–79), was the first complete scientific treatment of Russian history, from its origins up to 1774, since Karamzin's *History of the Russian State* (1818–29). Other works by him are *Historical Letters* (1858); *History of the Fall of Poland* (1863); and *The Political and Diplomatic History of Alexander I.* (1877).

SOLOVIEV, VLADIMIR SERGEVICH (1853–1900), Russian idealistic philosopher, critic and poet, son of the historian, Sergei Soloviev (*q.v.*), was born in Moscow on Jan. 16, 1853, and died at Uzkoe, near Moscow, on July 31, 1900. Vladimir studied theology at the University of Moscow, publishing in 1875 his Ph.D. thesis on *The Crisis of Western Philosophy.* After visiting England and Egypt, where he studied eastern philosophical ideas, he returned to Russia and was appointed reader in philosophy at Moscow university in 1877. But his outspoken criticism of the Government cut short his career as a lecturer; a speech against capital punishment lost him his readership at Moscow, and he was soon removed from the minor professorship at St. Petersburg (now Leningrad) to which he was next appointed. The rest of his life was devoted chiefly to writing. The chief tenet of Soloviev's theology, the union of eastern and western beliefs in a universal church, led him to take up a pro-Roman attitude for a time, and in 1889 he published in French *La Russie et l'Église Universelle* (3rd ed., 1922). He upheld the Christian ideal of universal brotherhood as opposed to Slavophilism. Philosophically he laid stress on the spirituality of all being, the idea of absolute one-ness, and the evolution of the God-man. His best known works are a *History of Materialism* (1894); *History of Ethics* (1896–98); *The Justification of the Good* (1898; Eng. trans. in Constable's Russian Library, 1915); *War, Progress, and the End of History, including a short story of the Anti-Christ* (1900; Eng. trans. 1915, with biographical notice by Dr. Hagberg Wright). *See* also *War and Christianity from the Russian Point of View,* three conversations, translated 1915, with an introduction by Stephen Graham. For a brief account of Soloviev's philosophy *see* L. M. Lopatin, *The Philosophy of Vladimir Soloviev* (1916).

SOLSTICE, in astronomy either of the two points at which the sun reaches its greatest declination north or south (Lat. *solstitium,* from *sol,* sun, and *sistere,* to stand still). Each solstice is upon the ecliptic midway between the equinoxes, and therefore 90° from each. The term is also applied to the time at which the sun reaches the point thus defined (about June 21 and Dec. 21).

SOLUNTUM (Gr. Σολόεις or Σολοῦς), an ancient town of Sicily, one of the three chief Phoenician settlements in the island, situated on the north coast, 10 m. E. of Panormus (Palermo), 600 ft. above sea-level, on the south-east side of Mte. Catalfano (1,225 ft.), in a naturally strong situation, and commanding a fine view. It was a Carthaginian possession until the First Punic War, when, after the fall of Panormus, it opened its gates to the Romans. Excavations have brought to light considerable remains of the ancient town, belonging entirely to the Roman period.

SOLUTIONS. When sugar is put in contact with water it dissolves and the liquid so obtained has the following properties which are characteristic of solutions:—

(1) It is homogeneous, *i.e.,* it is not possible to distinguish by any means, as for example by the most powerful microscope, parts which are sugar and parts which are water; the smallest amount which can be distinguished contains both sugar and water. In this a solution differs from a mixture which is heterogeneous, *i.e.,* in which it is possible to distinguish parts which are different from others. It may be supposed that in solutions the ultimate particles or molecules of which substances are made are intimately mingled together. If the single molecules of bodies could be made visible, the distinction between solutions and mixtures would fail. But except in some very special circumstances the smallest quantity of matter which can be distinguished contains some thousands of molecules, so that the distinction is of practical value.

(2) The composition of a solution can be varied: either water or sugar can be added to a sugar solution (within certain limits) and the solution still remains homogeneous. In this a solution differs from a chemical compound, which is homogeneous but has a definite composition which cannot be varied.

Types of Solutions.—The property of forming solutions is a very general one. All gases mix with each other in all proportions forming homogeneous gaseous "mixtures," which are technically solutions. Liquids may dissolve not only solids, but also other liquids and gases. It is also possible to obtain "solid solutions." Thus if two solid substances are melted together and then allowed to solidify, we may get a homogeneous solid substance of variable composition, containing the two substances, *i.e.,* a solid solution (*see* CHEMISTRY: *Physical*).

There is a limit to the amount of a solid substance which can dissolve in a given quantity of a liquid at any particular temperature. When this limiting amount is reached the solution is said to be *saturated.* The concentration of the dissolved substance in the saturated solution, expressed in a proper way, is known as its *solubility.* In some cases two liquids are completely miscible, *i.e.,* they form homogeneous solutions when mixed in all proportions. In others they are only partially miscible. Thus, when ether is added to water it dissolves at first, but ultimately a saturated solution is obtained and if more ether is added it forms a separate layer in contact with the water solution. This ether dissolves water from the aqueous solution until it is saturated with water. Thus two liquid layers are obtained, a saturated solution of ether in water and a saturated solution of water in ether.

In solutions of gases in liquids it is necessary to take into account another factor, the pressure of the gas. It was found by William Henry in 1803 that the solubility of a gas at a given temperature is proportional to its pressure (Henry's law). A familiar application of this is the soda-water syphon, which contains an aqueous solution of carbon dioxide, saturated at a pressure somewhat greater than the pressure of the atmosphere. Since this solution contains more carbon dioxide than corresponds to saturation at atmospheric pressure, gas is liberated when the excess pressure is released, causing effervescence.

Expression of Composition.—The substances of which a solution is composed are termed its components. Frequently the substance which dissolves is distinguished as the *solute,* and the liquid or medium into which it dissolves is called the *solvent.* But this is a matter of convenience, for there is no fundamental distinction between the two, and in many cases it is not clear which component is to be regarded as solute, and which as solvent. The composition of a solution is best expressed in terms of the relative numbers of the molecules of the components. Thus if we have a binary solution containing n_a molecules of a substance A, and n_b molecules of a substance B, the fraction $n_a/(n_a+n_b)=N_a$, *i.e.,* the ratio of the number of molecules of A to the total number of molecules in the solution, is known as the *molar fraction* of A. Similarly the ratio $n_b/(n_a+n_b)=N_b$ is the molar fraction of B.

The concentration of any component may be expressed as the amount of it in a given volume (volume concentration) or in a given weight (weight concentration) of the solution. If the amount of a substance be expressed in terms of the number of molecules, the corresponding molecular concentration is obtained. A convenient unit for stating molecular concentration is the *gram-molecule.* This is the amount of a substance which contains as many molecules as there are atoms in one gram of hydrogen. The number of gram-molecules of a substance in a litre of solution is often termed the *molar concentration;* whilst the same quantity in 1,000 grams of solvent is distinguished as the *molal concentration.*

THE PROPERTIES OF DILUTE SOLUTIONS

Vapour Pressures.—When a pure liquid, at a given temperature, is put in an evacuated space it gives off vapour until the

latter has a definite pressure which is known as the vapour pressure of the liquid. If a non-volatile substance (*i.e.*, a substance whose vapour pressure is inappreciable) is dissolved in the liquid it is found that the vapour pressure of the latter is thereby lowered. A. Wüllner found (1858–60) that the lowering of the vapour pressure was proportional to the concentration of the dissolved substance. Somewhat later (1886) François-Marie Raoult made the fundamental discovery that equal numbers of molecules of different substances, dissolved in the same solvent, produced the same lowering. A little later he found a more general relation, namely, that in dilute solutions the fractional lowering of the vapour pressure (*i.e.*, the ratio of the observed lowering to the original vapour pressure) was equal to the molar fraction of the dissolved substance. Thus if p_0 is the vapour pressure of the pure solvent, p that of the solution and N_2 the molar fraction of the solute, we have $(p_0-p)/p_0=N_2$. Table I. gives values of these two quantities obtained by Raoult for solutions of aniline, a liquid with a comparatively low vapour pressure, in ether.

TABLE I.
Fractional lowerings of the vapour pressure of solutions of aniline in ether

N_2 . . .	0·040	0·081	0·154	0·197	0·424	0·596
$\frac{P_0-p}{P_0}$ . .	0·038	0·077	0·148	0·205	0·496	0·687

Since $N_2=1-N_1$ (N_1 being the molar fraction of the solvent), it follows that $1-p/p_0=1-N_1$, or $p=p_0N_1$, *i.e.*, the vapour pressure of the solvent is proportional to its molar fraction. This relation is known as Raoult's law. Its limitations are discussed later.

Elevation of the Boiling Point.—The boiling point of a liquid is the temperature at which its vapour pressure is equal to the pressure of the atmosphere (boiling points are usually stated for the standard pressure of 76cm. of mercury). Since a solution of an involatile solute has a lower vapour pressure than the pure solvent at the same temperature, a greater rise of temperature is required to bring its pressure up to the atmosphere pressure; so that its boiling point is higher than that of the solvent. Since equal numbers of molecules of different solutes in the same solvent produce the same vapour-pressure lowering, they also cause the same elevation of the boiling point. The magnitude of the elevation produced by a given number of solute molecules depends, however, on the rate at which the vapour pressure of the solvent increases with the temperature, a quantity which is characteristic of each solvent, and which depends on the heat absorbed in vaporization. Thus every solvent has a characteristic *molecular elevation* of the boiling point, which is usually stated as the elevation produced by one gram-molecule of dissolved substance in 1,000 grams of solvent.

Making use of the laws of energy, J. H. van't Hoff showed in 1887 that the molecular elevation of a solvent, ΔT is given by $\Delta T=0{\cdot}002L_v/T^2$ where L_v is the heat absorbed in the vaporization of one gram of solvent and T is the absolute temperature at which it boils. The measurements of Raoult, Beckmann, and others showed that, while many solutes gave "normal" molecular elevations in good agreement with those calculated by van't Hoff, in some cases "abnormal" values are obtained, considerably greater or less than the van't Hoff figures. The study of these "abnormal" cases, as will be discussed later, played a great part in the subsequent development of the subject. Table II. gives the molecular elevations of some typical solvents as calculated by the van't Hoff formula, and the average observed elevations produced by "normal" solutes.

TABLE II.
Molecular elevations of the boiling point (for 1,000 grams of solvent)

Solvent	Boiling point	Molecular elevation	
		Calculated	Observed
Water	100° C	0·515	0·52
Carbon disulphide . .	46·2	2·41	2·37
Ethyl alcohol . . .	78·8	1·198	1·15
Methyl alcohol . . .	67	0·875	0·88
Acetic acid . . .	118·5	3·13	3·07
Benzene	80·3	2·67	2·67
Acetone	56·3	1·72	1·725

Freezing Points of Solutions.—The freezing point of a liquid is the temperature at which the solid form can exist in contact with the liquid. Thus at the freezing point and only at that temperature, can water and ice exist together. If the temperature is raised the ice melts to water; if it is lowered the water freezes. The freezing point of a solution is lower than that of the pure solvent; thus it is well known that sea water, which contains dissolved salts, freezes at a lower temperature than pure water. As early as 1788, Sir Charles Blagden made measurements of the freezing points of salt solutions and showed that the depression was roughly proportional to the concentration of the salt.

Van't Hoff showed that the depression of the freezing point is, like the elevation of the boiling point, proportional to the number of dissolved molecules. He obtained for the *molecular depression* of the freezing point, *i.e.*, the depression produced by one gram-molecule of a solute in 1,000 grams of solvent, an expression similar to that giving the molecular elevation, viz., $\Delta T=0{\cdot}002\ L_f/T^2$ where L_f is the heat absorbed in the fusion of one gram of solvent and T the absolute temperature of its freezing point. Table III. gives the molecular depressions of a few typical solvents, as calculated in this way.

TABLE III.
Molecular depressions of the freezing point (for 1,000 grams of solvent)

	Freezing point	Molecular depression (calculated)
Water	0·0° C	1·858
Benzene	5·5	5·19
Formic acid . . .	8	2·74
Acetic acid . . .	17	3·82
Phenol	41·5	6·81
Nitrobenzene . . .	3·9	6·80

The researches of Raoult, Beckmann and others showed that, whereas many substances gave rise to molecular depressions which agreed well with the calculated values, others behaved abnormally. Thus in aqueous solutions, the depressions produced by non-electrolytes are in good agreement with the calculated values, but those of strong electrolytes are considerably greater (*see* Table VI.) In benzene solutions, substances of a similar nature give rise to the normal depressions, but substances of a polar nature, *e.g.*, the alcohols, give smaller values.

Osmotic Pressures.—In 1748 the Abbé Nollet published the results of his experiments on the diffusion of substances through animal membranes. He found that if a vessel, full of spirits of wine, is closed with a bladder and immersed in water, the bladder expands and a considerable pressure, which may ultimately burst the bladder, is set up inside. Further experiments of this kind were made from time to time, but it was not until 1867 that Moritz Traube showed that similar effects could be obtained with artificially prepared membranes. W. Pfeffer in 1877 was the first to make measurements of the pressures set up. His membrane consisted of a deposit of copper ferro-cyanide, formed in the walls of a porous clay vessel by the interaction of solutions of copper sulphate and potassium ferro-cyanide. This membrane allows water to pass through it freely, but prevents the passage of dissolved substances such as cane sugar. Pfeffer's apparatus consisted (fig. 1) of the prepared porous pot, completely filled with a sugar solution and attached to a mercury manometer or pressure gauge. When the pot was immersed in water, the latter tended to diffuse through the walls into the sugar solution so as to dilute it, but the sugar was unable to diffuse outwards. The volume of sugar solution thus tended to increase (which forced the mercury up the manometer tube), giving rise to a pressure inside the cell which increased until it was sufficient to prevent

any more water diffusing into the solution. The hydrostatic pressure inside the cell when equilibrium is reached is the osmotic pressure of the solution.

In 1885 van't Hoff pointed out that, according to Pfeffer's measurements, dilute solutions obey the laws of gases. The osmotic pressure produced by a substance in solution is the same as the gas pressure which would be exerted if the same number of molecules were present in the same volume in the gaseous state. On this basis he built up a comprehensive theory of dilute solutions, and, making use of the laws of energy, derived the foregoing relations for the boiling points and freezing points of solutions. On account of this analogy between gases and solutions, the osmotic pressure has frequently been ascribed to the bombardment of the membrane by solute molecules which are unable to pass through it, and exert on it the same pressure as if they were present in the same space in the gaseous state. Its true origin, however, appears to be the tendency of the solvent to diffuse into the solution. When the two liquids are separated by a membrane which the solute molecules cannot pass, and are at the same pressure, the solvent will flow through the membrane into the solution. The osmotic pressure is the pressure which must be applied to the solution to stop this flow. That it is equal to the equivalent gas pressure is a consequence of the inter-relations of the properties of solvent and solute which are necessitated by the laws of energy. Exact measurements of the osmotic pressures of solutions have been made by H. N. Morse and J. C. W. Frazer (1902–12) in America and by the earl of Berkeley and E. G. J. Hartley in England (1906–09). These investigators found that in dilute solutions the osmotic pressure agrees with the corresponding gas pressure within the limits of experimental error; in more concentrated solutions deviations occur similar to those in gases at high pressures.

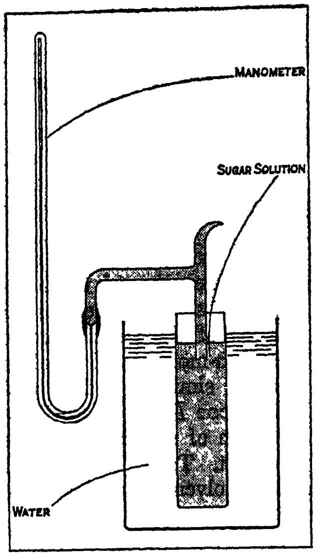


FIG. 1.—THE MANOMETER RECORDS PRESSURE PRODUCED BY WATER DIFFUSING INTO SUGAR SOLUTIONS

A simple means of recognizing solutions having the same osmotic pressure was discovered in 1888 by the botanist, Hugo de Vries. He observed the behaviour of the cells of certain plants, particularly *Tradescantia discolora,* in aqueous solutions. These cells consist of a woody framework, lined by a membrane containing a protoplasmic fluid which is permeable by water but not by dissolved substances. When such a cell is placed in a solution having the same osmotic pressure as that of the cell contents, it retains its normal appearance; if the osmotic pressure of the solution is greater or less the cell membrane expands or shrinks. It is thus possible to identify solutions of different substances which have the same osmotic pressure; that is, which are *isotonic.* Saline solutions which are isotonic with human blood are employed in surgery to replace a serious loss of blood.

CONCENTRATED SOLUTIONS

The Ideal Solution.—In solutions of two liquids, which are miscible in all proportions, and may both be volatile, each contributes to the total vapour pressure of the solution. If the relative proportions of the two substances in the vapour are known, the proportion of the total vapour pressure due to each component can be found. In this way the total vapour pressure is divided into the *partial vapour pressures* of the two components. Now in dilute solutions of a non-volatile solute, according to Raoult's law, the vapour pressure of the solvent is proportional to its molar fraction. A solution in which Raoult's law holds for all the components, over the whole range of compositions, is known as an *ideal* or perfect solution. Thus an ideal solution may be defined as one in which the partial vapour pressure of each component is proportional to its molar fraction through the whole range of composition, *i.e.,* Raoult's relation, $p=p_0N$, holds for the partial vapour pressure of each component.

The behaviour of solutions may be represented by a graph in which the partial vapour pressures of the components are plotted against the corresponding molar fractions (figs. 2 and 3). Points along the base line represent the molar fractions of the two substances, the extremities representing the two pure liquids, and the vertical distances from the base line the corresponding partial pressures. In ideal solutions the partial pressures, being proportional to the corresponding molar fractions, are represented by straight lines, extending from the point which represents the vapour pressure of the pure liquid to zero pressure at the other extremity of the base line. Deviations from the ideal relation are indicated by deviations of the partial vapour pressures from this straight line. The partial vapour pressures of many binary solutions were determined by Jan von Zawidski in 1900. Two substances which are closely related in constitution and properties usually form solutions which are nearly ideal. This is the case with ethylene bromide and propylene bromide (fig. 2). Substances not closely related may deviate. Fig. 3 shows some typical examples.

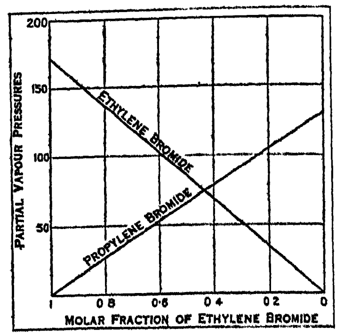

FIG. 2.—PARTIAL VAPOUR PRESSURES IN IDEAL SOLUTIONS

Deviations from Raoult's Law.—The deviations from Raoult's law which are exhibited in many solutions have been the subject of much experiment and speculation. On the one hand an explanation was sought in physical effects of the same nature as those which cause deviations from the law of perfect gases (J. D. van der Waals, 1890; J. J. van Laar, 1910). On the other hand a group of workers, led by Friedrich Dolezalek (1906), attempted to show that all deviations were capable of explanation by purely chemical effects, such as the formation of compounds between the components of the solution and "association" or the combination of two or more molecules of one component. While it has become certain that purely physical effects are capable of producing deviations, it cannot be said that chemical effects never occur.

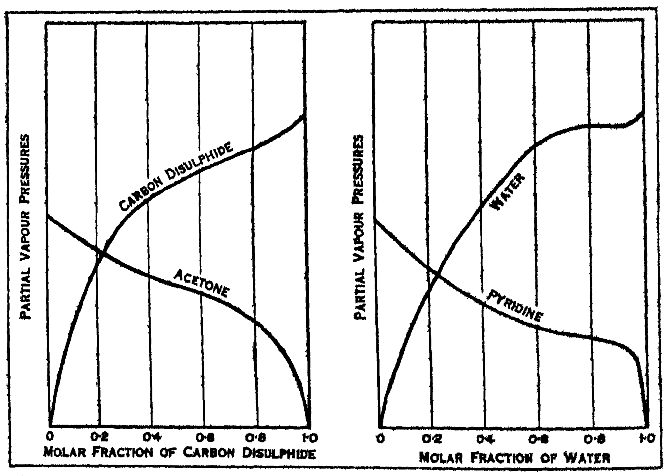

FIG. 3.—PARTIAL VAPOUR PRESSURES IN NON-IDEAL SOLUTIONS FOR ANY ONE CONSTITUENT

In a solution which obeys Raoult's law, the properties of a substance are the same as in its pure liquid, except in so far as they are modified by a reduction in the *number* of molecules present. Thus in an ideal solution containing 50% of molecules of a kind A, its vapour pressure is half that of pure liquid A at the same temperature. The change in vapour pressure is accounted

for entirely by the change in the number of molecules present in the liquid. Thus each molecule in the solution makes the same contribution to the vapour pressure as in the pure liquid. Now the molecules of a liquid are in a condition of thermal agitation, vibrating about their mean positions, and are held together by attractive or cohesive forces acting between them. Molecules which escape into the vapour are those which acquire sufficient energy to overcome the attractive forces exerted on them in the liquid. The greater these attractive forces, the less is the chance of a molecule getting loose, and the smaller is the vapour pressure. It is evident that in an ideal solution in which the vapour pressure of each component depends only on the number of molecules present, the forces exerted on each molecule must be the same as in the pure liquid.

It is easy to see that this can only be the case with substances which are very similar in nature. Thus if we have a liquid made up of molecules of a kind W, say water (fig. 4), and we replace half of them by molecules of another kind A, *e.g.,* alcohol, it is evident that the attractive forces acting on a single molecule W can only be the same in the pure liquid (*a*) and in the solution (*b*) if the attraction between a molecule W and a molecule A is the same as that between two molecules W. This can only be the case when the two substances are very closely related. If the molecules of a substance are held in the solution by forces greater than those acting in the pure liquid, the vapour pressure will be less than that given by Raoult's law; if the forces are less, the vapour pressure will be greater.

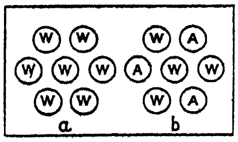

FIG. 4.—MOLECULAR CONDITION OF PURE WATER (a), (b) A SOLUTION OF ALCOHOL IN WATER

In a theory of solutions first put forward in 1916, J. H. Hildebrand has taken the internal pressure as a convenient measure of the attractive forces between molecule and molecule in a liquid. The internal pressure can be regarded as the cohesive force acting across a surface 1 sq.cm. in area in the interior of a liquid. If the internal pressures of two liquids are the same it may be possible to replace molecules of one by molecules of the other without changing the cohesion. If the internal pressures are different, it is unlikely that the cohesive forces acting on a molecule in the solution can be the same as in its pure liquid. Hildebrand has shown that liquids having nearly identical internal pressures do in fact form ideal solutions, while deviations from it are the greater the greater the difference of internal pressures. Table IV. gives the relative internal pressures of some typical substances (taking that of naphthalene as a standard).

TABLE IV.
Relative internal pressures in the liquid state

Hexane	0·56	Pyridine	1·10
Ethyl ether	0·66	Carbon disulphide	1·13
Ethyl acetate	0·83	Acetone	1·32
Carbon tetrachloride	0·84	Aniline	1·46
Benzene	0·94	Sulphur	1·70
Toluene	0·93	Iodine	1·85
Chloroform	0·95	Acetic acid	1·95
Naphthalene	1·00	Ethyl alcohol	2·90
Anthracene	1·05	Methyl alcohol	3·35
Nitrobenzene	1·07	Water	4·60

Activities.—In order to express the behaviour of non-ideal solutions, G. N. Lewis and M. Randall in 1907 introduced a quantity which they called the *activity.* In ideal solutions the partial vapour pressure of a component is proportional to its molar fraction; in non-ideal solutions the quantity to which it is proportional is called its activity, α, so that we have:

(1) in ideal solutions, $p=p_0N$;
(2) in non-ideal solutions $p=p_0\alpha$.

The ratio of the partial pressure of a component in a given solution to its vapour pressure as pure liquid (i.e., p/p_0), which in ideal solutions is equal to the molar fraction, is thus in general equal to the activity. The ratio of the activity to the corresponding molar fraction is called the *activity coefficient.* In ideal solutions the activity coefficient is therefore equal to unity; its difference from unity indicates the extent of the deviation from the ideal behaviour in the solution. Table V. gives the activities and activity coefficients of pyridine in pyridine-water solutions.

TABLE V.
Activities and activity coefficients of pyridine in pyridine-water solutions at 80·5° C.

Molar fraction of pyridine	1·000	0·892	0·747	0·541	0·336	0·160	0·000
Activity	1·000	0·802	0·686	0·581	0·474	0·438	0·000
Activity coefficient	1·000	0·956	0·963	1·074	1·412	2·737	..

Partially Miscible Liquids.—When the deviation from Raoult's law is very great two liquids may no longer form homogeneous solutions when mixed in all proportions. There may be a limit to the extent to which each liquid dissolves the other, and if the proportions are not within these limits two liquid layers are formed.

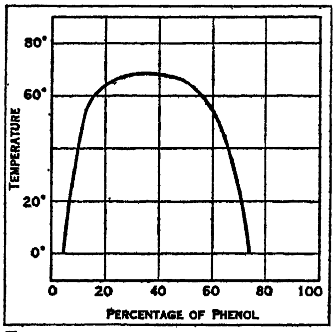

FIG. 5.—GRAPH SHOWING THAT ABOVE 68° WATER AND PHENOL ARE MISCIBLE IN ALL PROPORTIONS

The mutual solubility of two such liquids at different temperatures may be represented by a graph. Thus in fig. 5 the left-hand branch represents the solubility of water in phenol, the right-hand branch that of phenol in water. In this case the mutual solubility of the two liquids increases as the temperature rises and the two curves meet at a temperature of 68·8° C, which is known as the critical solubility temperature. Above this the liquids are miscible in all proportions.

It is usually the case that deviations from Raoult's law decrease, and the mutual solubility increases, as in fig. 5, with rise of temperature. But a few cases have been observed in which the reverse happens. Thus the mutual solubilities of triethylamine and water increase as the temperature is lowered, and there is a lower critical solubility temperature below which the two liquids are miscible in all proportions. Solutions of nicotine and water have the extraordinary property of having two critical solubility temperatures, an upper and a lower one. Thus above 210° and below 60° C the two liquids are miscible in all proportions; at intermediate temperatures they are only partially miscible. The mutual solubilities are thus represented by a closed curve. (*See* CHEMISTRY: PHYSICAL.)

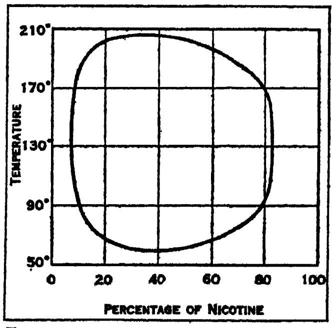

FIG. 6.—GRAPH SHOWING THAT WATER AND NICOTINE ARE MISCIBLE IN ALL PROPORTIONS BELOW 60° AND ABOVE 205°

SOLUTIONS OF ELECTROLYTES

Properties of Electrolytes.—An electrolyte is a substance which is a conductor of electricity either in the molten state or in solution (*see* ELECTROLYSIS, and ELECTRICITY, CONDUCTION OF, IN LIQUIDS). In order to account for this electrical conductivity, R. Clausius (1857) surmised that these substances were dissociated to some minute extent into electrically charged particles or ions which acted as carriers of the electric current. Soon after 1880 two lines of evidence converged to show that salt-like substances are in fact dissociated in solution to a considerable extent.

In the first place it was found that electrolytes in aqueous solution gave abnormally large values for the molecular elevation of the boiling point and the molecular depression of the freezing point. Table VI. shows a few values of the latter.

The molecular depressions produced by non-electrolytes are in fairly good agreement with the value 18·9 calculated by van't Hoff on theoretical grounds. The values for electrolytes are approximately twice this figure. Clearly, this could be interpreted to mean that the actual number of molecules in the solutions of the

Table VI.

Molecular depressions of the freezing point of water

Non-electrolytes		Electrolytes	
Solute	Molecular depression	Solute	Molecular depression
Urea	17·2	Hydrochloric acid	39·1
Acetamide	17·8	Nitric acid	35·8
Ethyl acetate	17·8	Caustic potash	35·3
Tartaric acid	19·5	Potassium chloride	33·6
Acetic acid	19·0	Sodium chloride	35·1
Cane sugar	18·5		
Ethyl alcohol	17·3		

latter is considerably greater than the number of molecules of the substance introduced, in fact that the electrolyte has undergone dissociation in solution. Van't Hoff however contented himself with introducing a factor *i*, the ratio of the observed to the normal calculated effect.

About the same time studies were being made of the electrical conductivities of solutions of electrolytes and their change with concentration. In order to find if there is any change in the state of the electrolyte when the concentration is varied, it is necessary to express the results as the quantity of electricity carried *by the same number of molecules* in the different solutions in a given time, the measurements being otherwise made under the same conditions. The quantity so obtained is the *molecular conductivity* of the electrolyte in solution. F. Kohlrausch found that the molecular conductivities of electrolytes increased with their dilution (*i.e.*, the amount of solvent containing one molecular weight in grams of the electrolyte), but that two classes could be distinguished:

(1) *Strong Electrolytes,* having large molecular conductivities which approach a constant limiting value when the dilution becomes very great. This class includes most salts; mineral acids such as nitric, hydrochloric, sulphuric; and strong bases such as caustic potash and caustic soda.

(2) *Weak Electrolytes,* the molecular conductivities of which are smaller and show no signs of reaching a constant value at great dilutions. To this class belong most organic acids and bases, *e.g.*, acetic acid; also ammonium hydroxide.

Electrolytic Dissociation.—These two groups of facts were correlated in the theory of electrolytic dissociation developed by Svante Arrhenius (1882–87), who conceived the idea that strong electrolytes are largely dissociated in their aqueous solutions into charged parts or ions. Thus a molecule of a binary electrolyte such as sodium chloride yields two ions on dissociation, a positively charged sodium ion and a negatively charged chloride ion: $NaCl \rightarrow Na^+ + Cl^-$; similarly barium chloride yields three ions: $BaCl_2 \rightarrow Ba^{++} + 2Cl^-$. In order to account for the change of molecular conductivity with dilution, Arrhenius assumed that at very great dilutions strong electrolytes were completely dissociated in this way. Now the molecular conductivity is determined by (1) the number of ions formed from one gram-molecule of the salt in solution, (2) their mobility or the rate at which they move in a given electric field. Arrhenius assumed that in fairly dilute solutions the mobility of the ions was constant, so that he ascribed the changes in the molecular conductivity to changes in the number of ions. Thus the decrease in the molecular conductivity as the concentration is increased is due to a decrease in the number of molecules dissociated into ions. The fraction dissociated, or degree of dissociation, in a given solution is the ratio of the molecular conductivity in that solution to its limiting value at infinite dilution (corresponding to complete dissociation).

In order to explain the abnormal freezing point depressions, etc., of solutions of electrolytes, Arrhenius supposed that the ions formed by dissociation had the same effect on the behaviour of the solutions as independent molecules. Then if the degree of dissociation is γ, the fraction of the electrolyte remaining undissociated is $1-\gamma$. If a molecule of an electrolyte γ dissociated into k ions, the number of ions formed is proportional to $k\gamma$, so that the total number of undissociated molecules and ions in the solution is greater than the number of molecules introduced in the ratio $(1-\gamma)+k\gamma=1+(k-1)\gamma$. Arrhenius clinched his theory by showing that the values obtained for this quantity by conductivity measurements were in good agreement with the van't Hoff factor *i*, as shown in Table VII.

Table VII.

Degree of dissociation, etc., of electrolytes (1 gram-molecule in 10 litres of water)

	Degree of dissociation	i from freezing point	$i=1+(k-1)\gamma$
Hydrochloric acid	0·90	1·98	1·90
Sulphuric acid	0·60	2·06	2·20
Sodium hydroxide	0·88	1·91	1·88
Potassium chloride	0·86	1·82	1·85
Sodium chloride	0·82	1·90	1·82
Silver nitrate	0·86	1·60	1·86
Zinc sulphate	0·38	0·98	1·38

In solutions of weak electrolytes the limiting value of the molecular conductivity, corresponding to complete dissociation, cannot be determined directly, because at the greatest dilution at which measurements can be made these substances are only partially dissociated. It can, however, be calculated by means of a relation given by Kohlrausch; and from it the degrees of dissociation are obtained in the same way as with strong electrolytes.

Difficulties of Arrhenius' Theory.—The theory of Arrhenius met at first with vigorous opposition. The more conservative chemists refused to accept the view that common salt, for example, is largely dissociated in aqueous solutions into sodium ions and chloride ions. This opposition was largely based on a misconception of the nature of ions and in course of time died down. Nevertheless, although the Arrhenius theory provided a new basis for our knowledge of salt solutions and served to inspire a great number of investigations for more than 20 years, there remained outstanding difficulties.

Thus it was found that, in some of their properties, the behaviour of salt solutions was more uniform than the varying degrees of dissociation calculated from conductivity measurements, according to the Arrhenius theory, would lead us to expect. For example, A. A. Noyes found in 1904 that the optical rotatory powers of β-bromocamphoric acid and its metallic salts in solutions of equivalent strengths were almost identical, although conductivity measurements indicated degrees of dissociation varying from 70 to 93%. Noyes remarked, "If there were not other evidence to the contrary these facts would almost warrant the conclusion that the salts are completely ionized up to the concentration in question." Again, it was found by Ostwald that the variation of the degree of dissociation of weak electrolytes with their concentration was in accordance with the ordinary laws of chemical equilibrium, but no such relation could be obtained with strong electrolytes. Although attempts were made to introduce the effect of the electrical charges of the ions on the equilibrium between undissociated salt and its ions, no satisfactory explanation was found. In the earlier stages the methods of measurements available were not very accurate and it was only possible to show the approximate equality of the degree of dissociation as given by conductivity measurements with the value corresponding to the van't Hoff factor *i*. In later years many exact measurements were made of the two quantities, but these only confirmed or accentuated the differences between them.

The Theory of Complete Dissociation.—As we have seen, Arrhenius made the initial assumption that the speeds of ions in a given electric field were independent of the concentration, at any rate in dilute solutions; so that changes in the molecular conductivities were due to changes in the degree of dissociation. In view of the difficulties mentioned above, the correctness of Arrhenius' assumption began to be questioned. Might not a strong electrolyte be completely dissociated at all concentrations, the changes in the molecular conductivities being due to changes in the mobility of the ions? This view, which had been tentatively

suggested earlier by W. Sutherland, S. R. Milner and others, was put in a definite form by N. Bjerrum in 1918.

The early prejudice against the idea of electrolytic dissociation had now disappeared. In the light of the greater insight into the structure of salts afforded by studies in atomic physics, the dissociation of salts into ions appeared, not as something abnormal and astonishing, but as a natural consequence of their structure. Thus the work of Sir William Bragg and his son, W. L. Bragg, on crystal structures has shown that crystals of sodium chloride, for example, are built up of sodium ions and chloride ions arranged alternately on a cubic lattice. Each sodium ion is surrounded at equal distances by six chloride ions and there is no reason for believing that any of these is associated with it by a special bond. It is thus reasonable to suppose, unless evidence to the contrary is found, that there is no tendency for the ions to "pair off" into molecules in solution. It was therefore necessary to see if the properties of salt solutions could be explained in any other way than as due to variations in the degree of dissociation.

Activities of Strong Electrolytes.—The actual behaviour of solutions of strong electrolytes, like that of solutions of miscible liquids, can be expressed in terms of *activities*. In this case, however, it is convenient to take as standard the behaviour of very dilute solutions, in which Raoult's law holds, and in which the activity of each ion can be put equal to its concentration. Owing to deviations from Raoult's law and to other effects, including the possible combination of ions to form molecules, the behaviour of more concentrated solutions may not be identical with that of an ideal completely dissociated solution of the same concentration. The quantities which express the actual behaviour of ions in such solutions, in place of their concentrations, are their activities.

The activity of a strong electrolyte is taken as the (geometrical) mean of the activities of its ions and in very dilute solutions is also equal to the concentration. Activities can be determined by a variety of methods, from measurements of the freezing points, boiling points and related properties of solutions, and in the case of slightly soluble salts, from their solubilities. These measurements all depend on the equilibrium of the solution with either the solvent in the solid or vapour state or, in the case of solubilities, with the solid solute. They all depend on the tendency of either solvent or solute to leave the solution. Thus the vapour pressure measures the tendency of the solvent to leave the solution and enter the coexistent vapour; a change in the freezing point measures the corresponding change in the tendency of the solvent to separate out as the solid, and a change in solubility measures the change in the tendency of the solute to deposit from the solution. These are all measures of what G. N. Lewis has called the "escaping tendency" of either solvent or solute from the solution. The escaping tendencies of solute and solvent are inter-related and a change in the one can be calculated, by thermodynamical methods, from the corresponding change in the other. In ideal solutions the escaping tendencies of the components are related in a simple way to their molar fractions (or molecular concentrations, suitably expressed). The activities are the quantities which measure the escaping tendencies in actual solutions.

If we divide the activity of an electrolyte by its concentration (usually the molal concentration is used) we get the *activity coefficient*. The activity coefficients of many strong electrolytes in aqueous solution have been determined by G. N. Lewis, G. A. Linhart, A. A. Noyes, H. S. Harned and others. American physical chemists have been particularly active in this field. Table VIII. gives some representative values.

The effect of concentration on the activity coefficients of a few typical electrolytes is shown in fig. 7. As the concentration increases the activity coefficients at first decrease. Usually they reach a minimum and then rise, becoming greater than unity in concentrated solutions. This behaviour is decisive against Arrhenius' theory. An activity coefficient less than unity might possibly be interpreted as a degree of dissociation, but some other explanation must be found for activity coefficients which are greater than unity. The magnitude of the effect is shown by the fact that the activity coefficient of hydrochloric acid in a solution in which its molal concentration is 16, is 43·2. This cannot possibly be interpreted as a "degree of dissociation."

Table VIII.

Activity coefficients of strong electrolytes at 25° C in aqueous solutions

Molal concentration	Hydrochloric acid	Lithium chloride	Sodium chloride	Potassium chloride	Potassium hydroxide	Sulphuric acid
0·01	0·924	0·922	0·922	0·922	0·920	0·617
0·05	0·860	0·843	0·842	0·840	0·822	0·397
0·1	0·814	0·804	0·798	0·794	0·792	0·313
0·5	0·762	0·754	0·689	0·682	0·740	0·178
1·0	0·823	0·776	0·650	0·634	0·775	0·150
3·0	1·35	1·200	0·704	0·575	1·136	0·166
5·0	2·51	..	0·892	..	..	0·242

The Ionic Strength.—In dilute solutions the change of the activity coefficient with concentration is very uniform. In solutions of salts of the same type the activity coefficients are practically identical up to a molal concentration of 0·1. In mixed solutions containing two or more salts of the same type, it is found that the activity coefficient depends only on the total ion concentration when the latter is small. In studying mixtures containing ions of different types (*i.e.*, having different electric charges), G. N. Lewis and M. Randall found that the effect of a bivalent ion on the activity coefficients of the salts in the solution was four times that of a univalent ion, or that the effect is proportional to the square of the ionic charge. They therefore introduced a quantity which they termed the *ionic strength* of the solution; this is obtained by multiplying each ion concentration by the square of its valency (or electric charge in electronic units) and dividing the sum by two. They were then able to state the rule that *in dilute solutions the activity coefficient of a particular strong electrolyte is the same in all solutions of the same ionic strength.*

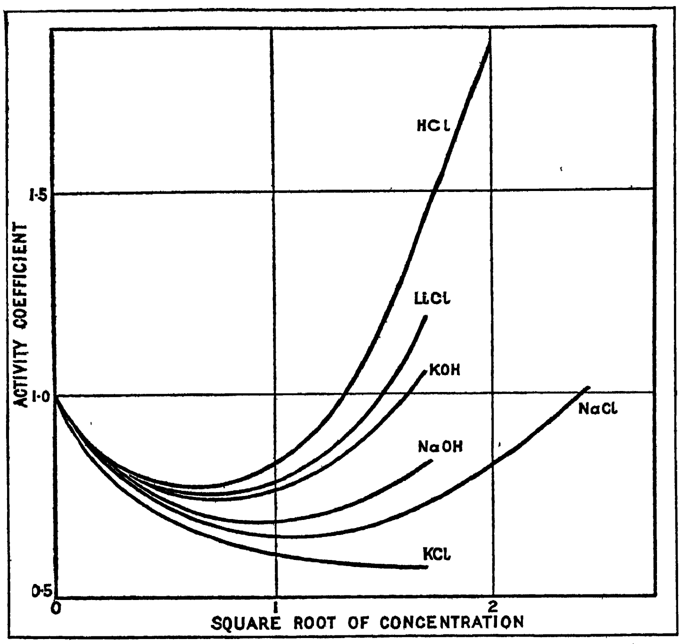

Fig. 7.—Activity co-efficients of some strong electrolytes

At concentrations greater than about 0·1 molal each electrolyte begins to exhibit an individual behaviour, both in solutions of it alone and in mixed solutions.

Interionic Attraction Theory.—That the electric forces between ions must have an important influence on the properties of salt solutions was pointed out by van Laar (1900), Sutherland (1902) and Bjerrum (1909). The first successful calculation of these forces was made in 1913 by S. R. Milner. Unfortunately his calculations were mathematically very complex, since he evaluated the electric forces between a given ion and every other ion present in the solution and summed the effect for all the ions.

His results could only with difficulty be applied to actual cases. J. Chandra Ghosh in 1918 attempted a partial solution of the problem, and in 1923 P. Debye and E. Hückel found a comparatively simple method of calculating the effect. Since ions with electric charges of opposite sign attract each other and the attraction is greater the closer the ions approach, it is more difficult to remove a given ion from a strong solution than from a more dilute one. Thus the electric forces cause a decrease in the "escaping tendencies" of the ions, and the more concentrated the solution the greater is the effect.

Debye and Hückel based their calculations on the fact that a particular ion tends to attract into its vicinity ions of unlike sign and to repel those of like sign, so that on the average it is surrounded by more ions of unlike sign than of like sign. Making use of the Boltzmann equation, which gives the distribution of molecules in a region under the action of electric and other forces, and the Poisson equation (*see* ELECTROSTATICS), which defines how the forces vary in a known distribution of electric charges, they were able to calculate the work done in removing an ion, on account of the electric forces exerted on it by the surrounding ions. This is the quantity which determines the deviation from Raoult's law. In dilute solutions, in which the diameter of the ions is small in comparison with their distance apart, they found that the calculation gave the result that the activity coefficient of a strong electrolyte is given by the formula

$$\log f = z_1 z_2 B \sqrt{\mu}$$

where f is the activity coefficient and μ the ionic strength of the solution; z_1 and z_2 are the charges (in electronic units) on the two ions of the substance and B is a constant which is approximately $\frac{1}{2}$ for aqueous solutions at 0° C. Not only does this formula agree with the ionic strength rule, already stated, that the activity coefficient of a strong electrolyte is determined by the ionic strength of the solution, but it is in numerical agreement with the values in dilute solutions.

Debye and Hückel attempted to account for the individual behaviours of salts in more concentrated solutions by taking account of (1) the diameters of the ions, (2) the effect of the dissolved electrolytes on the dielectric constant of the solution. Although they were able to account qualitatively for the general form of the activity coefficient curve, they were not completely successful in calculating the activity coefficients from the known properties of the substances.

An important factor to be taken into account is the effect of the electric forces round the ions on the molecules of the solvent. Water, like all substances which dissolve strong electrolytes, has strongly "polar" molecules, *i.e.*, its molecules are attracted towards regions in which electric forces are greatest. Thus water molecules tend to congregate round ions, forming "water sheaths," which in strong solutions keep them apart, thus acting in the opposite sense to their attractive forces. It is probable that the rise in the activity coefficient in strong solutions is due to this effect.

Hydration of Ions.—It had previously been found in many phenomena that, in aqueous solutions, ions behaved as if they were associated with a certain amount of water, but in spite of many attempts no reliable estimate was made of the degree of hydration or amount of water associated with each ion. In 1919 K. Fajans showed that, knowing the lattice energies (*see* CRYSTALLOGRAPHY) of solid salts, it was possible to determine the *energies of hydration* of the ions. This quantity is the amount of energy liberated when a free ion in the gaseous state is introduced into water. Table IX. gives the energies of hydration of ions (in kilogram calories per gram-atom) obtained by W. M. Latimer (1926).

TABLE IX. *Hydration Energies of Ions*

H^+	242	Rb^+	72	Ba^{++}	289
Cu^+	128	Zn^{++}	494	Al^{+++}	1,068
Li^+	119	Mg^{++}	454	Cl^-	(161)
Ag^+	107	Cd^{++}	440	Br^-	(140)
Na^+	96	Ca^{++}	379	I^-	(122)
K^+	77	Sr^{++}	338		

As Max Born first pointed out in 1920, the energies of hydration of ions agree closely with the changes of electrical energy to be expected according to electrical theory, when a charged sphere the size of which is equal to that of the ion is moved from a vacuum into a medium having the dielectric constant of water. (The figures for Cl^-, Br^-, I^-, given in parentheses are calculated in this way.) It thus appears that the energy effects on the solutions of ions are electrical in origin, and this gives powerful support to the idea that the "water of hydration" of ions is held by purely electrical forces and is not chemically combined with the ion. (For colloidal solutions, *see* COLLOIDS.)

BIBLIOGRAPHY.—Comprehensive accounts of solutions are to be found in most treatises on physical chemistry. Specialized works are: A. Findlay, *Osmotic Pressure* (1919); C. A. Kraus, *The Properties of Electrically Conducting Systems* (1922), deals exhaustively with electrolytic solutions; J. H. Hildebrand, *Solubility* (American Chemical Society monographs), treats the subject mainly from the point of view of the author's own theory; D. A. Clibbens, *The Principles of the Phase Theory* (1923), deals with the solubility relations of mixtures of salts. (J. A. V. B.)

SOLUTRIAN PERIOD, in archaeology, the name given by G. de Mortillet to the second stage of his system of cave-chronology, synchronous with the third division of the Quaternary period, from the Solutré cave, Mâcon district, Saône-et-Loire. The period is chiefly characterised by "laurel-leaf" blades (knives or daggers) of flint, beautifully flaked on both sides, and readily distinguishable from the flints of the preceding Mousterian epoch. Large thin spear-heads, scrapers with the edge not on the side but on the end, flint knives and saws, all still chipped, not ground or polished, arrow-heads with tang and shoulder on one side only, are also characteristic of this transitional period. Among the fauna are the horse, reindeer, mammoth, cave lion, rhinoceros, bear and urus. Solutrian "finds" have also been made in the caves of Les Eyzies and Laugerie Haute, and in the lower beds of Creswell cave, Derbyshire. The Solutrian technique or fashion of flint-working represents the acme of palaeolithic craft.

See J. Déchelette, *Manuel d'Archaeologie,* vol. i. (1908), A. Keith, *Antiquity of Man,* vol. i., 2nd ed. (1925).

SOLVAY, a village of Onondaga county, New York, U.S.A., on Lake Onondaga, adjoining Syracuse on the west; served by the New York Central railroad and for freight also by the Lackawanna. Pop. (1920) 7,352, and it was 7,986 in 1930. It is a manufacturing and residential suburb, with large soda-ash works (employing 3,000 persons), a steel plant and various other industries. The village was incorporated in 1894.

SOLWAY FIRTH, estuarine inlet of the Irish Sea, 50 m. long, between England and Scotland. The breadth at the mouth is 32 m.; near the head, where the Solway viaduct of the L.M.S. railway crosses the firth, it is nearly 1½ miles. The general direction is north-easterly from the mouth. The Scottish counties bordering the firth are Wigtownshire, Kirkcudbright and Dumfriesshire; the English coast belongs to Cumberland. On the English side the low Solway plain borders the firth, except for a short distance above St. Bee's Head. The Scottish shore, however, is not continuously flat, and such elevations as Criffell (1,866 ft.), Bengairn and Cairnharrow, above Wigtown bay, rise close to it. The Cree and other streams enter Wigtown bay; the Dee, Kirkcudbright bay; and the Nith discharges through a long estuary. The Annan has its mouth near the town of that name; and the Esk and Eden have theirs at the head of the firth, in Cumberland. On this shore Morecambe bay receives the Wampool and Waver, the Ellen has its mouth at Maryport, and the Derwent from the Lake District at Workington. The waters of the firth are shallow, and a tidal bore occurs periodically.

SOMA, in Vedic India personified the *Asclepias acida,* whose sap, fermented, is an intoxicant. As a Bacchus-like god Soma is lauded in 114 hymns of the *Rig-veda* IX. and as a co-equal of Indra, Agni and Rudra in other Books. Its uses, like its name (*Haoma* in the *Avesta*), go back to Iranian times, and it was prized both in India and Irān as a medicine conducing to longevity. The celestial variety, distinct from that of earth, was drunk by the gods, and incited Indra to establish the universe. In the post-Vedic Epics Soma is the Moon, who wanes when drunk by gods but is replenished by the Sun. For the theft of the first *soma* by Indra's eagle *see* ZEUS and ODIN.

SOMA, in biology, the tissues that form the body of the organism in contrast to the reproductive tissues. (*See* ZOOLOGY; EMBRYOLOGY; HEREDITY.)

SOMALILAND, a country of East Africa, so named from its Somali inhabitants. It is sometimes called the "Eastern Horn of Africa," because it projects sharply into the Indian ocean. In general outline it is an irregular triangle, with apex at Cape Guardafui. From the apex the north side extends over 600 m. along the south shore of the Gulf of Aden westwards to Tajura bay, and the east side skirts the Indian ocean south-west for some 1,200 m., the Tana river being about the limit of Somali settlement. Inland the limits of Somaliland correspond roughly with the Shoan and Harrar hills, the Galla district south of Shoa and east of Lake Rudolph and 40° E. as the western limit. The triangular space thus roughly outlined has an area of about 396,000 square miles. It includes the 36,000 sq.m. of Jubaland added to Italian Somaliland by transferences from Kenya Colony. It is partitioned as under, the figures for area and population being in some cases estimates:—

	Area in square miles	Population
British Somaliland	68,000	344,000
French Somaliland	8,000	56,000
Italian Somaliland	190,000	700,000
Abyssinian Somaliland*	100,000	350,000
Total	366,000	1,450,000

*This is a rough estimate. *See* also ABYSSINIA.

Somaliland was not generally adopted as the name of the country until the early years of the 19th century. The northern and central districts were previously known as Adel, the north-east coast as Ajan. By the ancients the country was called *regio aromatica,* from the abundance of its aromatic plants.

Physical Features.—The region as a whole is a vast plateau of an average elevation of 3,000 ft., bounded westwards by the Ethiopian and Galla highlands and northwards by an inner and outer coast range, skirting the south side of the Gulf of Aden in its entire length from the Harrar uplands to Cape Guardafui.

The incline is uniformly to the south-east, and apart from the few coast streams that reach the Gulf of Aden during the rains, all the running waters are collected in three rivers—the Nogal in the north, the Webi Shebeli in the centre, and the Juba (*q.v.*) in the south—which have a parallel south-easterly direction towards the Indian ocean, though the Juba alone reaches the sea. The Nogal sends down a turbulent stream during the freshets, while the Shebeli, notwithstanding the far greater extent of its basin, does not reach the sea. At a distance of about 12 m. from the coast it is intercepted by a line of dunes, which it fails to pierce, and is deflected southwards, flowing in this direction for nearly 170 m. parallel with the coast, and then disappearing in a swampy depression (the Bali marshes) before reaching the Juba estuary.

The Somaliland plateau is chiefly composed of gneiss and schist. In the north the plateau is overlain by red and purple unfossiliferous sandstones, capped near its edge by a cherty limestone also unfossiliferous but possibly of Lower Cretaceous age. The plains inland from Berbera, and the maritime margins between the coast and foot of the plateau, consist of Lower Oolitic limestones.

Temperature varies from 60° or less in the early morning to 100° or over in the early afternoon. On an average the coast-belt temperatures are some 10° higher than those of the plateau. Four seasons are recognized—January–April, very dry and great heat; May–June, cooler and the "heavy" rains; July–September, the season of extreme heat and the south-west monsoon; October–December, the "light" rains.

Flora and Fauna.—The flora of Somaliland is isolated because it lies east of the great belt of high ground of East Africa. In the mountainous north the flora resembles, however, to some extent, that of the Galla country and Abyssinia. The greater part of the country is covered either with tall coarse grasses (these open plains being called *ban*), or more commonly with thick thorn-bush or jungle, among which rise occasional isolated trees. The prevalent bush plants are *khansa* (umbrella mimosa), acacias, aloes, and, especially, *Boswellia* and *Commiphora,* which yield highly fragrant resins and balsams, such as myrrh, frankincense (*olibanum*) and "balm of Gilead." The billeil is a thorn-bush growing about 10 ft. high and covered with small curved hooks of great strength. The bush contains also numerous creepers, one of the most common is called the *armo.* Of the thorns, the *guda* and the *wadi* often grow from 30 to 50 ft. high and have large flat-topped branches. In places there are forests of these trees. On the summit of the Golis range the cedars form forests. Among the larger trees are the mountain cedar, reaching to 100 ft.; the *gob,* which bears edible berries in appearance something like the cherry with the taste of an apple, grows to some 80 ft., and is found fringing the river beds; the *hassādan,* a kind of euphorbia, attaining a height of about 70 ft.; and the *darei,* a fig tree.

Somaliland is rich in the larger wild animals. Among them are the lion (Somali name *libah*) and elephant; the black or double-horned rhinoceros, common in central Ogaden; leopards, abundant in many districts, and daring—they have given their name to the Webi Shebeli ("River of the Leopards"); panthers; spotted and striped hyenas (the latter rare); foxes, jackals, badgers and wild dogs; giraffes and a great variety of antelopes. The antelopes include the beisa oryx, fairly common and widely distributed, the greater and lesser kudu (the greater kudu is not found on the Ogaden plateau); the Somali hartebeest (*Bubalis Swaynei*), found only in the Haud and Ogo districts; waterbuck, rare except along the Webi Shebeli and the Nogal; the dol or Somali bushbuck; the dibatag or Clarke's gazelle; the giraffe-like gerenuk or Waller's gazelle, very common; the aoul or Soemmering's gazelle, widely distributed; the dero (*Gazella Speki*); and the small dikdik or sakaro antelope, found in almost every thicket. The zebra (*Equus grevyi*) is found in Ogaden and places to the south, the wild ass in the northern regions. There are wart hogs, baboons (maned and maneless varieties), a tree monkey, jumping shrews, two kinds of squirrel, a small hare, rock rabbits and a weasel-like animal which hunts in packs. Ostriches are found in the open plains; the rivers swarm with crocodiles, but hippopotami are rare. Birds of prey are numerous and include eagles, vultures, kites, ravens and the carrion stork. Among game birds are three varieties of bustard, guinea fowl, partridges, sand grouse and wild geese. Snakes are common, an adder, a variegated rock snake and a black snake called *muss* being those most dreaded.

Inhabitants.—The Somali belong to the Eastern (Ethiopic) Hamitic family of tribes, of which the other chief members are the neighbouring Galla and Afar, the Abyssinian Agau and the Beja tribes between the Nubian Nile and the Red sea. They have been identified with the people of Punt, known to the Egyptians of the early dynasties. The Somali, however, declare themselves to be of Arab origin, alleging their progenitor to have been a certain Sherīf Ishak b. Ahmad, who crossed from Hadramut with 40 followers about the 13th century. Other traditions trace their origin to the Himyaritic chiefs Sanhāj and Samamah, said to have been coeval with a King Afrikus, who is supposed to have conquered Africa about A.D. 400. These legends should perhaps be interpreted as pointing to a series of Arab immigrations, the last two of which are referred to the 13th and 15th centuries.

The present Somali peoples are possessed of no general type. They are not pure Hamites, and their physical characteristics vary considerably, showing signs of interbreeding with Galla, Afar, Arabs, Abyssinians and negroes. They are a race of magnificent physique, tall, active and robust, with fairly regular features, but showing negro blood in their complexion and hair.

There are four classes in Somaliland: (1) nomads who breed camels, ponies, sheep and cattle, live on milk and meat, and follow the rains in search of grass; (2) settled Somali, comparatively few, living in or near the coasts; (3) outcast races, not organized in tribes but living scattered all over Somaliland; they are hunters, workers in iron and leather, and the chief collectors of gum and resin; (4) traders. The national dress is the "tobe," a simple cotton sheet of two breadths sewn together, about 15 ft. long. Generally, it is thrown over one or both shoulders, a turn given round the waist, and allowed to fall to the ankles. The "tobes"

are of all colours from brown to white. A ceremonial "tobe" of red, white and blue, each colour in two shades, with a narrow fringe of light yellow, is sometimes worn.

The Somali are a fighting race and all go armed with spear, shield and short sword and, since they have been procurable, guns. During the rains intertribal lootings of cattle are common, save where the authority of the paramount power is sufficient to preserve peace. Among certain tribes those who have killed a man have the right to wear an ostrich-feather in their hair. They are great talkers, keenly sensitive to ridicule, and quick-tempered. The Somali love display; they are inordinately vain and avaricious; they are very intelligent and quick witted and make loyal and trustworthy soldiers. The great interest in life with the nomads, the most numerous class, is their camels.

The Somali are divided into a multiplicity of *rers* or *fakidas* (tribes, clans). Three main divisions have been clearly determined.

1. The *Hashiya* (Abud's *Asha*), with two great subdivisions: *Daroda,* with the powerful Mijertins, War-Sangeli, Dolbohanti and others; and *Ishak,* including the Gadibursi, Issa (Isa), Habr-Wal, Habr-Tol, Habr-Yuni, Babibili, Bertiri. All these claim descent from a member of the Hashim branch of the Koreish (Mohammed's tribe), who founded a powerful State in the Zaila district. All are Sunnites, and, although still speaking their Somali national tongue, betray a large infusion of Arab blood in their oval face, somewhat light skin, and remarkably regular features. Their domain comprises the whole of British Somaliland, and probably most of Italian Somaliland.

2. The *Hawīya,* with numerous sub-groups, such as the Habr-Jalet, Habr-Gader, Rer-Dollol, Daji, Karanlē, Badbadan, Kunli, Bajimal and Ugass-Elmi; mostly fanatical Mohammedans forming the powerful Tarika sect, whose influence is felt throughout all the central and eastern parts of Somaliland. The Hawīya domain comprises the Ogaden plateau and the region generally between the Nogal and Webi-Shebeli rivers. Here contact has been chiefly with the eastern Galla tribes.

3. The *Rahanwīn,* with numerous but little-known sub-groups, including, however, the powerful and warlike Abgals, Barawas, Gobrons, Tuni, Jidus and Kalallas, occupy in part the region between the Webi-Shebeli and Juba, but chiefly the territory extending from the Juba to the Tana, where they have long been in contact, mostly hostile, with the Wa-Pokomo and other Bantu peoples of British East Africa. Of all the Somali the Rahanwīn betray the largest infusion of negroid blood.

Of the outcast races the best known are the Midgan, Yebir, and Tomal. The Midgan, who are of slightly shorter stature than the average Somali, are the most numerous of these peoples. They are great hunters and use small poisoned arrows to bring down their game. The Yebir are noted for their leather work, and the Tomal are the blacksmiths of the Somali.

Prehistoric Remains.—The discovery of flint implements of the same types as those found in Egypt, Mauritania, and Europe shows Somaliland to have been inhabited by man in the Stone age. That the country was subsequently occupied by a more highly civilized people than the Somali of to-day is evidenced by the ruins which are found in various districts. Many of these ruins are attributable to the Arabs, but older remains are traditionally ascribed to a people who were "before the Galla." Blocks of dressed stone overgrown by grass lie in regular formation; a series of parallel revetment walls on hills commanding passes exist, as do relics of ancient water-tanks. Of more recent origin are the ruins known as Galla graves (*Taalla Gālla*). These are cairns of piled stones, each stone about the size of a man's head.

Exploration.—The ancients were acquainted with the northern coast, and the Arabs had settlements on the Eastern coast. In modern times the exploration of the country dates from the occupation of Aden by the British in 1839, Aden being the chief port with which the Somali of the opposite coast traded. The first explorers of the interior were officers of the Indian army quartered at Aden—Lieut. Cruttenden (1848), Lieut. (afterwards Captain Sir Richard) Burton, and Lieut. J. H. Speke (the discoverer of the Nile source). In 1854 Burton, unaccompanied, penetrated inland as far as Harrar. Later on an expedition was attacked by Somali near Berbera, both Burton and Speke being wounded, and another officer, Lieut. Stroyan, R.N., killed. For 20 years afterwards no attempt was made to explore the interior. The occupation of Berbera by the Egyptians in 1875 led, however, to new endeavours. Of those who essayed to cross the waterless Haud more than one lost his life. In 1883 a party of Englishmen—F. L. and W. D. James (brothers), G. P. V. Aylmer, and E. Lort-Phillips—penetrated from Berbera as far as the Webi-Shebeli, and returned in safety. Surveys of the country between the coast and the Webi-Shebeli and also east towards the Wadi Nogal were executed by Maj. H. G. C. Swayne and his brother Capt. E. J. E. Swayne between 1886 and 1892.

The first person who reached the Indian ocean, going south from the Gulf of Aden, was an American, Dr. A. Donaldson Smith (b. 1864). He explored (1894–95) the headstreams of the Shebeli, reached Lake Rudolf, and eventually descended the Tana river to the sea. Meanwhile the greater part of the eastern seaboard had fallen under Italian influence. In 1891 Brichetti-Robecchi went from Mukdishu to Obbia, and thence crossed through Ogaden to Berbera on the Gulf of Aden. In 1892 Capt. Vittorio Bottego and a companion left Berbera and made their way past Imi to the upper Juba, which Bottego explored to its source, both travellers finally making their way via Lugh to the east coast. In 1895 Bottego, with three European companions, left Brava to investigate the river system north of Lake Rudolf, and succeeded in tracing the Omo to that lake. Subsequently in the Abyssinian highlands the expedition was attacked by Galla and Capt. Bottego was killed. Dr. Sacchi, who was returning to Lugh with some of the scientific results of the mission, was also killed by natives. An English expedition under H. S. H. Cavendish (1896–97) followed somewhat in Donaldson Smith's steps, and the last named traveller again crossed Somaliland in his journey from Berbera via Lake Rudolf to the Upper Nile (1899–1900). In 1902–03 a survey of the Galla-Somali borderlands between Lake Rudolf and the upper Juba was executed by Capt. P. Maud of the British army. Military operations against the "Mad" Mullah in the period 1900–20 led to a more accurate knowledge of the south-eastern parts of the British protectorate and of the adjacent districts of Italian Somaliland. Of later travellers the duke of the Abruzzi, in 1919–20 explored the mid region of the Webi-Shebeli. The demarcation of the new frontier between Kenya and Italian Somaliland, in 1926, rectified several errors on the map.

BRITISH SOMALILAND

The British Somaliland protectorate extends along the Gulf of Aden for about 400 m. from the Lahadu Wells, near Jibuti, in the west, to Bandar Ziyada in 49° E., 180 m. W. of Cape Guardafui, and stretches from the coast inland for a breadth varying from 80 to 220 miles. The protectorate is bounded west by French Somaliland, south-west by Abyssinian territory, and south-east and east by Italian Somaliland.

Topography.—Between the Harrar plateau and Cape Guardafui the coast ranges maintain a mean altitude of from 4,000 to 5,000 ft., and fall generally in steep escarpments down to the sandy lowlands skirting the Gulf of Aden. At some points the cliffs, furrowed by deep ravines, approach close to the sea; elsewhere the hills leave a considerable maritime plain between their base and shore line. South of Berbera are two ranges, nearly parallel with the coast. The inner and loftier range is that of Golis, about 9,500 ft. high, its crest covered with mountain cedar. The country between the two ranges is known as Guban. South of the Golis the ground falls gradually to the central plateau known as the Haud, a waterless but not unfertile district. The Haud (only the northern part of which is British territory—the rest is Abyssinian) consists partly of thorn jungle, the *haud* of the Somali, partly of rolling grass plains, called *ban,* and partly of semi-desert country called *aror.*

The average annual rainfall at Berbera is about 8 in., and more than half of this amount has fallen in one day. The mean annual rainfall is greater on the slopes of the ranges, by which the moisture-bearing clouds are intercepted. These slopes are the home of

aromatic flora which yields myrrh and frankincense. The chief domestic animals are the camel and the ass, both of prime stock. The camels make excellent mounts, swift and hardy. The Somali have also large numbers of oxen, sheep and goats. They possess a hardy breed of ponies, for which the Dolbahanta country is famed.

Towns and Trade.—Berbera (*q.v.*), the capital and chief seaport, is in regular communication by mail boat with Aden. About 45 m. W. of Berbera is the exposed port of Būlhar. Close to the French frontier stands the seaport of Zaila (*q.v.*). East of Berbera are Las Korai, Karam, Hais and other small seaports. Inland the most important settlement is Hargeisa (*i.e.*, little Harrar), 60 m. S.S.W. of Būlhar, a centre for caravans from Shoa and Ogaden. Sheikh, Burao and Bohotle are all on the caravan route from Ogaden to Berbera. Transport is either by camel or motor car; no other means of conveyance are used. There is a motor road from Berbera to Hargeisa (130 m.) and another motor road via Sheikh and Burao to Enigavo in the east (300 miles).

Gums and resins are collected for export, fibre is obtained from the aloe plant, ostriches are reared for their feathers, and millet is cultivated, but the chief wealth of the people consists in their livestock. A large number of sheep and goats and smaller numbers of cattle are exported, and on occasion thousands of camels (as during the World War, for the Egyptian Expeditionary Force). The most valuable export is that of skins, the Somali goat and sheep skins being of very high quality; they go chiefly to the United States. The imports are mainly sheeting and longcloth, dates, rice and sugar. Formerly American sheeting had a practical monopoly; since 1923 it has had to meet Japanese competition. A carrying trade of fair size used to be done with Abyssinia via Zaila; it has been largely superseded by the railway from Jibuti, French Somaliland, to Addis Ababa. In 1899–1900, when the French railway had just been begun, the value of trade in British Somaliland was £751,000; by 1902–03 it was £487,000. Twenty years later the value of transit trade with Abyssinia via Zaila, which cannot compete with the railway beyond Harrar, was only £33,000, but the total trade had reached £561,000. In 1927 imports were valued at £427,000 and exports at £357,000. The mineral resources of the country are undeveloped; it is known to contain oil fields, coal and mica in the coastal region.

Revenue is derived mostly from customs, and is much below the cost of administration. In 1910–11 revenue was £30,000 and expenditure £99,000. In 1926–27 the figures were: revenue £90,–000 (customs £67,000), expenditure £149,000. Normal deficits are made good from the British Treasury, which also met the cost of military operations. Since 1921–23 part of the deficit had been met not by free grant but by loan, and hopes of balancing the budget were entertained. Both executive and legislative power is in the hands of the governor. District commissioners supervise local affairs.

HISTORY

An Arab sultanate, with its capital at Zaila (Zeyla), was founded by Koreishite immigrants from the Yemen in, it is said, the 7th century A.D. In the 13th century it had become a comparatively powerful state, known as the empire of Adel. In the 16th century the capital of the state (in which Arab influence was a decreasing factor) was transferred to Harran (*q.v.*). The state was harassed by Galla invaders in the 17th century, and broke up into petty independent emirates and sultanates under Somali chiefs. Zaila became a dependency of Yemen and thus nominally part of the Turkish empire. The British connection with the Somali coast dates from the early years of the 19th century and arose from the desire of the East India Company to obtain a suitable place "for the harbour of their ships without any prohibition whatever." Treaties with that object in view were concluded with the Sultan of Tajura and the governor of Zaila in 1840 and from that time the Indian Government exercised considerable influence on the Somali coast, though British authority was not definitely established. In 1874–75 the ambition of Ismail Pasha, khedive of Egypt, led him to occupy the ports of Tajura, Berbera and Bulhar as well as Harrar in the hinterland. In 1884, in consequence of the revolt of the mahdi in the Egyptian Sudan, the khedival garrisons were withdrawn. Thereupon Great Britain, partly because they were on the route to the East *via* the Suez canal, occupied Zaila, Berbera and Bulhar. During 1884, 1885, 1886 treaties guaranteeing British protection were concluded with various Somali tribes and in 1888 the limits of the British and French spheres were defined, all claims to British jurisdiction under the 1840 treaties in the Gulf of Tajura and the islands of Musha and Bab being abandoned. The other inland boundaries of the protectorate were defined by agreements with Italy (1894) and Abyssinia (1897). At first regarded as a dependency of Aden the protectorate was transferred to the Foreign Office in 1898. In 1905 it passed under the control of the Colonial Office.

The "Mad" Mullah.—In 1899 troubles arose with a mullah of the Habr Suleiman Ogaden tribe, Mohammed bin Abdullah, who had acquired great influence in the Dolbahanta country and had married into the Dolbahanta Ali Gheri. He had made several pilgrimages to Mecca, where he had attached himself to a sect which enjoined strict observance of the tenets of Islam and placed an interdiction on the use of the leaves of the kat plant—much sought after by the coast Arabs and Somali for their stimulating and intoxicating properties. At first the mullah's influence was exerted for good, and he kept the tribes over whom he had control at peace. Accredited with the possession of supernatural powers he gathered around him a strong following. In 1899 he began raiding tribes friendly to the British, and declared himself the mahdi. From that time, with certain intervals of inactivity, the "mad" mullah, as he was popularly called, caused infinite trouble for many years. The tribes hostile to the mullah sought British aid and operations were undertaken by Col. (Sir) E. J. E. Swayne. After severe fighting in 1900–01 the enemy was driven to take refuge into the Mudug territory (Italian Somaliland). On Oct. 6 of that year the British forces—Somali levies and Yaos from Nyasaland—were ambushed in dense bush at Erigo and lost 101 killed and 85 wounded. While the mullah was repulsed, and retreated to Galadi, Col. Swayne was unable to continue the pursuit. In 1903 another campaign was undertaken with the co-operation of the Abyssinians and the Italians, the base chosen being the roadstead of Obbia in Italian territory. Brigadier-General W. H. Manning was in command and besides Indian and African troops a small number of British and Boer mounted infantry were employed. Again there was desperate fighting and though Galadi was occupied the mullah broke away and crossing the British lines of communication established himself in the Nogal district. During the operations 200 Yaos and Sikhs under Lieut.-Col. Plunket were attacked (April 17) and overwhelmed. All ten British officers were slain; of the whole force only 40 Yaos, of whom 36 were wounded, escaped. Reinforcements bringing the fighting force up to 7,000 men were sent, and Major-General Sir C. C. Egerton assumed supreme command. In a pitched battle fought on Jan. 10, 1904 at Jidballi in the Nogal country the enemy were routed, losing over 1,000 men in killed alone, while the British loss in killed and wounded was 58. By May the mullah had been driven out of the British protectorate and became a refugee among the Mijertin. It was decided therefore to abandon offensive operations. In 1905 the Italians effected an arrangement apparently satisfactory to all parties.

Dervish Power Broken.—For some three years the mullah remained quiescent, but in 1908 he quarrelled with the Mijertins and in 1909 he was again raiding tribes in the British protectorate. The British Government (the Asquith cabinet) came to the conclusion that another expedition against the mullah would be useless; that they must either effectively occupy the whole of the protectorate, or else abandon the interior completely. The latter course was decided upon, and during the first months of 1910 the advanced posts were withdrawn and the British administration confined to the coast towns.

This policy of "strict coast concentration" before long broke down. Efforts to restore order were inevitable; they began inauspiciously. In Aug. 1913 a camel constabulary party under R. C. Corfield was cut up, Corfield being killed. In May 1914 Mr. (later Sir) Geoffrey Archer became commissioner (a title changed in 1919 to that of governor), and further operations were

authorised. Major T. A. Cubitt inflicted severe punishment on the dervishes in Nov. 1914–Feb. 1915, but the mullah subsequently again overran a large part of the protectorate. An end was, however, put to his activities in 1920, when by operations planned by Archer and carried out by Lt.-Col. (later Sir) Gerald Summers almost the whole dervish force was destroyed. The success of these operations was primarily and mainly due to the Royal Air Force. The mullah himself escaped, fleeing into Abyssinian Somaliland, where, at the town of Imi, he died in Jan. 1921.

The overthrow of the mullah marked the deliverance of the country from 21 years of dervish oppression. The succeeding period was chiefly notable for the efforts made, with satisfactory results by the British authorities to improve the moral and material conditions of the Somalis. (F. R. C.)

FRENCH SOMALILAND

French Somaliland (*Côte française des Somalis*) lies at the entrance to the Red sea. The sea frontier extends from Ras Dumeira on the Straits of Bab-el-Mandeb, a little north of Perim Island, to Ras Gurmarle, a few miles south of the Gulf of Tajura. The protectorate is bounded north by the Danakil country; south by British Somaliland; west by the Harrar province of Abyssinia. It extends inland at its greatest depth about 130 miles.

The country consists chiefly of slightly elevated arid plains, largely waterless save along the southern frontier. The Gulf of Tajura is 28 m. across at its entrance and penetrates inland 36 miles. At its western end an opening 870 yd. wide leads into the circular bay of Gubbet-Kharab (Hell's Mouth), behind which rise a chaotic mass of volcanic rocks, destitute of vegetation and presenting a scene of weird desolation.

The inhabitants are, on the north side of the Gulf of Tajura, chiefly Danakils (Afars, *q.v.*); on the southern shore Galla and Somali. There are a number of Arabs, Abyssinians, Indians and about 400 Europeans. The chief town, which is also the only good harbour and the seat of administration, is Jibuti (*q.v.*), pop. (1921), 8,366 (of whom 354 were Europeans).

The value of this small, largely arid and sparsely populated region lies in Jibuti, the only French port on the Suez canal route and the main artery of trade with Abyssinia. The railway to Addis Ababa, owned by a French company, begun in 1897, was, after many delays, completed in 1917. Four-fifths of the trade of Jibuti is in the conveyance of goods to or from Abyssinia. It serves also as a coaling station, the coal being previously imported. The chief local industries are shark and mother-of-pearl fisheries and the collection of salt from the Bahr-Assal.

The colony is administered by a governor, assisted by a nominated council composed of official and unofficial members. It is self-supporting, the budget (1927) balancing at about 6,000,000 francs.

History.—French interest in the Somali and Danakil coasts dates from the days of the Second Empire. In 1856 France acquired Ambabo and Obok. It was not, however, until 1883 that, in consequence of events in Egypt and the Sudan (*see* EGYPT: *History*), formal possession was taken of Obok by the French Government. Between 1883 and 1887 treaties with Somali sultans gave France possession of the whole of the Gulf of Tajura. An agreement with Great Britain (Feb. 1888) fixed the southern limits of the protectorate; protocols with Italy (Jan. 1900 and July 1901) the northern limits. The transference of the seat of government to Jibuti in May 1896 and the building of the railway to Addis Ababa (completed in 1917) gave the protectorate a stability which it had previously lacked. Salt mines were opened in 1912 and there was later some development of agriculture, but the colony depends for prosperity upon its port and the transit trade with Abyssinia. During 1917–18 Lej Yasu, the deposed emperor of Abyssinia, tried to raise the tribes against the French, but his efforts failed. Apart from occasional raids by the nomads the country, then and subsequently, remained tranquil.

ITALIAN SOMALILAND

Italian Somaliland extends on the coast from Bandar Ziyada, a point on the Gulf of Aden intersected by 49° E., eastward to Cape Guardafui, and thence southward to Dick's Head. Bounded north and east by the Indian ocean it is bounded south by Kenya Colony and west by Abyssinian and British Somaliland. From the east coast the protectorate extends inland from 100 to 300 miles.

The coast-line is largely rock-bound and little indented, and throughout its extent there is only one tolerable natural harbour, Kismayu. The coast presents a succession of hills (fringed by a narrow margin of beach) until Cape Guardafui is reached. Cape Guardafui is in 11° 75′ N., 51° 26′ 32″ E., and forms, as it were, the tip of the Horn of Africa. The cape, which faces north and east, presents on its northern face a nearly vertical wall of rock rising from the sea to a height of 900 feet. The water is deep right to the base of the cliff, and owing to the winds and the strength of the ocean currents, navigation is dangerous. The headland is known to the Somali as Girdif or Yardaf.

Rounding Guardafui the coast trends southwards, and some 90 m. from that cape is Ras Hafun or Medudda—the most easterly point of the continent of Africa—being in 10° 45′ S., 51° 27′ 52″ E., or about 1½ m. east of Guardafui. Ras Hafun is a rocky peninsula rising 600 ft. above the sea, and is connected with the mainland by an isthmus 12 m. long.

The interior of the country presents, in general, the same arid aspect as the rest of Somaliland. Italian territory has a depth from the coast of 200 to 250 m., the frontiers with Abyssinia and British Somaliland being arbitrary straight lines. The most fertile districts lie between the equator and 4° N. This region includes the lower courses of the Webi-Shebeli and the Juba. The sand dunes which separate the Shebeli from the sea have already been mentioned; the land beyond, under irrigation, is very fertile. But the most fertile region is the valley of the lower Juba, which is annually inundated. For over 100 m. on either bank of the river is a rich strip of land varying in width from a few hundred yards to over 4 m. at the estuary. Away from the river and in the region west of it, ceded to Italy by Great Britain in 1925, the normal scrub and thorn plains prevail.

Towns, Trade and Administration.—The chief towns are on the coast. They are Mukdishu, population over 20,000, the seat of government, Brava (4,000), Marka (5,000), Warsheik (3,000) and Kismayu (10,000). These are all in the southern part of the protectorate and are known generically as El-Benadir (the ports), a name also applied to the coast between the ports. Obbia, 5° 22′ N., and Illig in 7° 60′ N., are points of departure for the Ogaden and Dolbahanta countries. Alula, on the Gulf of Aden, is the chief town of the Mijertin Somali.

In the interior are Bardera, on the left bank of the Juba, Lugh, a populous city also on the left bank of the Juba and about 240 m. from the coast, and further inland is Dolo at the confluence of the Daua and Ganale to form the Juba.

While the Somali carry on their usual trade in dressed skins, cattle, frankincense, myrrh and gum arabic, the Italians, since 1922, have taken up in earnest the cultivation of cotton, the sugar cane, rice, durra and maize in the Webi Shebeli and Juba regions. Some few hundreds settled on the land, the total number of Italians in the colony in 1928 being about 1,000. Over 11,000 ac. were under cotton in 1927, the production being 13,000 centals. Irrigation works were carried out in the Webi Shebeli region in the hinterland of Mukdishu, wherefrom a railway was begun to aid the colonists. By 1928 some 40 m. of line had been built, the ultimate objective being Lugh. About 3,000 m. of roads had also been built. Though cotton and other crops were promising, the chief exports up to 1928 were the produce of the Somalis, as indicated and of goods from Abyssinia.

The southern part of the country had been a Crown colony under a civil governor since 1910; the northern part consisted of sultanates under Italian protection. Over this northern part direct Italian authority was imposed in 1925–26 and in 1927, with the Jubaland province transferred from Kenya, the whole of Italian Somaliland was divided into seven districts, each under a civil commissioner responsible to the governor. The colony has required constant and heavy subventions from Italy, colonial revenue (up to 1925) being scarcely a tenth of the cost of

administration, which was 24,000,000 lire in 1924.

History.—The Somali coast, as has been seen, early fell under Muslim influence. The towns on the eastern seaboard, of which Mukdishu and Brava were the chief, formed part of the Zenj "empire" (*see* Zanzibar) and shared its fate, being conquered in turn by the Portuguese (16th century), the imans of Muscat (17th century), and the sultans of Zanzibar (1866). By treaties with Somali sultans in 1889 and by agreements with England, Zanzibar and Abyssinia, the coast east of the British Somali protectorate fell within the Italian sphere of influence. (*See* Africa: *History.*) In Aug. 1892 the sultan of Zanzibar leased the Benadir ports of Italy for 50 years. They were administered first by the Filonardi company, and from 1898 by the Benadir company. By an agreement dated Jan. 13, 1905, the sultan of Zanzibar ceded his sovereign rights in the Benadir ports to Italy in return for the payment of a lump sum of £144,000. Thereafter the Italian Government assumed the direct administration of the ports. In 1905 also Great Britain leased to Italy a piece of land near Kisimayu.

A notable event in the history of the protectorate at the beginning of the 20th century was the co-operation of the Italian authorities in the campaigns against the Mullah Abdullah.

The station of Lugh, the most advanced point occupied by Italy, had been founded by Capt. Vittorio Bottego in 1895. In 1896 negotiations were opened for defining the Italian-Abyssinian frontier in the Somali regions. In 1897 it was agreed that from the point on the British Somaliland frontier where 47° E. intersected 8° N. the frontier line should be drawn, at a distance of about 180 m. from the Indian ocean, to the Juba. By the arrangement of 1907 with the Negus Menelik (ratified by a convention dated May 16, 1908) the Benadir coast obtained a suitable hinterland. As a result of the Treaty of London of 1915, and colonial rearrangements consequent on the World War, Britain ceded to Italy in 1925 territories on the right bank of the Juba with the port of Kisimayu (*see* Jubaland).

The *Bibliografia etiopica* of G. Fumagalli (Milan, 1893) includes works dealing with Somaliland.

SOMBART, WERNER (1863–), German economist, was born at Ermsleben in the Harz on Jan. 19, 1863; he studied in Pisa and Berlin, and in 1888 became secretary of the chamber of commerce in Bremen. He taught at the University of Breslau from 1890, at the Berlin commercial high school from 1906, and in 1917 was appointed professor at the University of Berlin. Sombart has written prolifically on economic, historical and social problems. His best known work is *Der Moderne Kapitalismus*, which first appeared in 1902 and was followed by a series of monographs, the substance of which was largely incorporated in the much enlarged and amended second edition of 1916. The work was finally completed in 1926 by two volumes bringing the history of capitalism down to the present day. Sombart combines great learning with brilliancy of style and fertility of ideas.

Sombart's published works include *Sozialismus und soziale Bewegung im 19. Jahrhundert;* the 10th revised edition of this treatise, published in 1924, bears the title: *Der proletarische Sozialismus. Wirtschaft und Mode* (1902), *Die deutsche Volkswirtschaft im 19. Jahrhundert* (1903, 5th ed. 1921), *Das Proletariat* (1906), *Das Lebenswerk von Karl Marx* (1909), *Die Juden und das Wirtschaftsleben* (1911), *Luxus und Kapitalismus* (1912), *Die Ordnung des Wirtschaftslebens* (1925). Sombart is the editor of *Grundlagen und Kritik des Sozialismus* (1919).

SOMBOR, a town of the Voivodina, Yugoslavia. Pop. (1921) 31,332, two-thirds Serbian. It is situated in a fertile plain and is the centre of the corn and cattle trade of an extensive area.

SOMERS, JOHN SOMERS (or Sommers), Baron (1651–1716), English lord chancellor, was born on March 4, 1651, near Worcester, the eldest son of John Somers, an attorney, and of Catherine Ceaverne of Shropshire. Educated at Worcester and at Trinity College, Oxford, he studied law under Sir Francis Winnington, and soon became intimate with the leaders of the country party, especially with Essex, William Russell, and Algernon Sidney, but never entered into their plans so far as to commit himself beyond recall. He was reputed to have written the *Just and Modest Vindication of the Two Last Parliaments*, in answer to Charles II.'s declaration of his reasons for dissolving them. This, however, was by Sidney, though probably Somers was responsible for the final draft. As counsel for the sheriffs Pilkington and Shute before the court of King's Bench, and junior counsel in the trial of the seven bishops, Somers won a reputation which was further enhanced by the part which he took in the secret councils which preceded the revolution. Elected to the Convention Parliament, he was appointed one of the managers for the Commons in the conferences between the houses, and was further distinguished by being made chairman of the committee which drew up the Declaration of Right.

In May 1689 Somers was made solicitor-general and knighted, and he now became William III.'s confidential adviser. In the controversy which arose between the Houses on the question of the legality of the decision of the court of King's Bench regarding Titus Oates, and of the action of the Lords in sustaining this decision, Somers was again the leading manager for the Commons, and has left a clear and interesting account of the debates. He was appointed chairman of the select committee of the House of Commons on the Corporation Bill (1690), by which those corporations which had surrendered their charters to the Crown during the last two reigns were restored to their rights. On March 23, 1693, the great seal having meanwhile been in commission, Somers was appointed lord-keeper and a privy councillor. Somers now became the most prominent member of the Junto, the small council which comprised the chief members of the Whig party. When William left in May 1695 to take command of the army in the Netherlands, Somers was made one of the seven lords-justices to whom the administration of the kingdom during his absence was entrusted; and he was instrumental in bringing about a reconciliation between William and the princess Anne.

In April 1697 Somers became lord chancellor, and was created a peer by the title of Baron Somers of Evesham. Somers had been free from attack at the hands of political opponents; but his connection in 1699 with Captain William Kidd, to the cost of whose expedition Somers had given £1,000, afforded an

opportunity for a vote of censure, in the House of Commons which was rejected by 199 to 131. The attack was renewed shortly on the ground of his having accepted grants of Crown property to the amount of £1,600 a year, but was again defeated. On the subject of the Irish forfeitures a third attack was made in 1700, a motion being brought forward to request the king to remove Somers from his counsels; but this again was rejected by a large majority. In consequence, however, of the incessant agitation Somers was finally compelled to resign. In 1701 he was impeached by the Commons for his share in the negotiations relating to the Partition Treaty in 1698, and defended himself most ably before the house, answering the charges seriatim. The impeachment was voted and sent up to the Lords, but was there dismissed. On the death of the king Somers retired into private life, but he actively opposed the Occasional Conformity Bill (1702), and in 1706 was one of the managers of the union with Scotland. In the same year he carried a bill regulating and improving the proceedings of the law courts. He was made president of the council in 1708 upon the return of the Whigs to power, and retained the office until their downfall in 1710. He was also president of the Royal Society from 1699–1704. He died on April 26, 1716. Somers wrote *The History of the Succession of the Crown of England,* as well as several poems and pamphlets.

For a contemporary character of Somers Addison's paper in the *Freeholder* for the 14th of May 1716 should be referred to; and there is in Macaulay's *History* (iv. 53) an eloquent tribute to his character and comprehensive learning. A catalogue of his publications will be found in Walpole's *Royal and Noble Authors.*

SOMERSET, EARLS AND DUKES OF. In the 11th century Somerset and Dorset were under the jurisdiction of one sheriff, and for a considerable period titles derived from each of these shires were borne by the same person. (*See* DORSET, EARLS, MARQUESSES AND DUKES OF.)

The earldom of Somerset in the Beaufort family dated from 1397, in which year it was granted by Richard II. to JOHN BEAUFORT (*c.* 1373–1410), the eldest of the three illegitimate, but afterwards legitimated, sons of John of Gaunt, duke of Lancaster, by Catherine, wife of Sir Hugh Swynford, and daughter of Sir Payne Roelt. He was followed in the earldom successively by his three sons: Henry, who died unmarried in 1418; John (1404–1444), who in 1443 was created earl of Kendal and duke of Somerset, both of which titles became extinct at his death; and Edmund, who was created earl of Dorset in 1441, marquess of Dorset in 1443, and duke of Somerset in 1448. (*See* SOMERSET, EDMUND BEAUFORT, DUKE OF.) On the execution of Edmund's son Henry, 5th earl and 2nd duke of Somerset, by the Yorkists in 1464, his titles were forfeited by act of parliament; but his brother Edmund was from that date styled duke of Somerset by the Lancastrian party till his death in May 1471, when the house of Beaufort became extinct. (*See* BEAUFORT.) The title, conjoined with the dukedom of Richmond, was, however, borne by Henry Fitzroy, illegitimate son of Henry VIII., from 1525 till his death without heirs in 1536.

EDWARD SEYMOUR, duke of Somerset (*q.v.*), known as the Protector, was the first of the line of dukes to which the holder of the title at the present day belongs, having been created Viscount Beauchamp of Hache, Co. Somerset, in 1536; earl of Hertford in 1537; and in 1547 Baron Seymour and duke of Somerset. His honours, which were entailed on the issue of his second in priority to that of his first marriage, being forfeited by attainder in 1552, Robert Carr became earl of Somerset (*q.v.*) in 1613, but died without male issue in 1645, when his title became extinct. A curious incident in the history of this title was the grant by Charles I. in 1644 of a commission to Edward Somerset, son of Henry, 1st marquess of Worcester, empowering him to fill up certain blank patents of peerage with a promise of the title of duke of Somerset for himself. After the Restoration this instrument was cancelled in consequence of a resolution of the House of Lords declaring it to be "in prejudice to the peers"; and the grantee, who had meantime succeeded to the marquessate of Worcester, surrendered his claim to the dukedom of Somerset in Sept. 1660. In the same month the dukedom of Somerset and barony of Seymour were restored to WILLIAM SEYMOUR (1588–1660), great-grandson of the Protector, who in 1621 inherited the titles of earl of Hertford and Baron Beauchamp which had been granted to his grandfather Edward Seymour in 1559, and who, in 1640, had himself been created marquis of Hertford. He died in Nov. 1660, a few weeks after his restoration to the dukedom, and was succeeded by his grandson William, 3rd duke of Somerset (*c.* 1651–1671). As the latter died unmarried, the Somerset title devolved on John Seymour (*c.* 1628–1675), the 2nd duke's fifth and youngest son, at whose death without issue in 1675 the marquessate of Hertford became extinct; his cousin Francis Seymour (1658–1678) becoming 5th duke of Somerset.

CHARLES SEYMOUR, 6th duke of Somerset (1662–1748), who succeeded his brother Francis, the 5th duke, was educated at Trinity college, Cambridge; and in 1682 he married Elizabeth, daughter of Joceline Percy, earl of Northumberland, who brought him immense estates, including Alnwick castle, Petworth, Syon House and Northumberland House in London. (*See* NORTHUMBERLAND, EARLS AND DUKES OF.) In 1683 Somerset received an appointment in the king's household, and two years later a colonelcy of dragoons; but at the revolution he bore arms for the prince of Orange. He became a great favourite with Queen Anne, receiving the post of master of the horse in 1702. He made friends with the Tories, and succeeded in retaining the queen's confidence, while his wife replaced the duchess of Marlborough as mistress of the robes in 1711. In the memorable crisis when Anne was at the point of death, Somerset acted with Argyll, Shrewsbury and other Whig nobles who, by insisting on their right to be present in the privy council, secured the Hanoverian succession to the Crown. Dismissed from his office of master of the horse in 1716, he retired into private life, and died at Petworth on Dec. 2, 1748. At the death of his son ALGERNON (1684–1750), 7th duke, without male issue, the earldom of Hertford, and the baronies of Beauchamp and of Seymour of Trowbridge became extinct; and the dukedom of Somerset, together with the barony of Seymour, devolved on a distant cousin, Sir Edward Seymour, 6th baronet of Berry Pomeroy, Devonshire. (*See* SEYMOUR OR ST. MAUR.)

The Seymours of Berry Pomeroy were the elder branch of the family, being descended from the protector Somerset by his first marriage, the issue of which had been excluded from succession to the titles and estates until after the failure of the issue of his second marriage. (*See* above.) SIR EDWARD SEYMOUR (1695–1757), who thus became 8th duke of Somerset, was grandson of Sir Edmund Seymour, Speaker of the House of Commons in the reign of Charles II. EDWARD ADOLPHUS, 12th duke (1804–1885), held various offices in Lord Melbourne's administration from 1835 to 1841; was a member of Lord John Russell's cabinet in 1851; and first lord of the admiralty from 1859 to 1866. In 1863 he was created Earl St. Maur of Berry Pomeroy. He married (1830) Jane Georgiana, youngest of the three celebrated daughters of Thomas Sheridan, who was the "Queen of Beauty" at the famous Eglinton Tournament in 1839. The duke was the author of *Christian Theology and Modern Scepticism* (1872), and *Monarchy and Democracy* (1880). At his death the family titles, except the earldom of St. Maur, which became extinct, devolved on his two brothers successively.

See SEYMOUR OR ST. MAUR, and the authorities there cited.

SOMERSET, EDMUND BEAUFORT, DUKE OF (*c.* 1404–1455), was the younger son of John, earl of Somerset, and grandson of John of Gaunt, duke of Lancaster. He was taken prisoner at Baugé in 1421 during his first campaign, and did not return to England till 1431. He was then styled earl of Mortain, and in 1432 was one of the envoys to the council of Basel. In 1436 he served at the relief of Calais, two years later he commanded with some success in Maine, and in 1440 recovered Harfleur. Next year he was made earl, and in 1443 marquess of Dorset. In 1444 on the death of his elder brother he became duke of Somerset. As head of the Beaufort party he was the rival of Richard of York, whom in 1446 he superseded as lieutenant of France. He lacked statesmanship, and as a general could do nothing to stop French successes. The loss of Rouen and Nor-

mandy during the next four years was precipitated by his incompetence, and his failure naturally made him a special object of Yorkist censure. The fall of Suffolk left Somerset the chief of the king's ministers, and the Commons in vain petitioned for his removal in January 1451. In spite of York's active hostility he maintained his position till Henry's illness brought his rival the protectorate in March 1454. For a year he was kept a prisoner in the Tower "without any lawful process." On the king's recovery he was honourably discharged, and restored to his office as captain of Calais. Mistrust of Somerset was York's excuse for taking up arms. The rivalry of the two leaders was ended by the defeat of the Lancastrians and death of Somerset at St. Albans on May 22, 1455.

For further information *see* Sir James Ramsay's *Lancaster and York* (Oxford, 1892), and C. Oman's *Political History of England, 1377–1485* (1906), with authorities there cited. (C. L. K.)

SOMERSET, EDWARD SEYMOUR, DUKE OF (*c.* 1506–1552), protector of England, born about 1506, was the eldest surviving son of Sir John Seymour (d. 1536) of Wolf Hall, Wiltshire, by his wife Margaret, eldest daughter of Sir Henry Wentworth of Nettlested, Suffolk. The Seymours claimed descent from a companion of William the Conqueror, who took his name from St. Maur-sur-Loire in Touraine; and the protector's mother was descended from Edward III. Edward was "enfant d'honneur" to Mary Tudor at her marriage with Louis XII. in 1514, served in Suffolk's campaign in France in 1523, and accompanied Wolsey on his embassy to France in 1527. Henry VIII., to whom he became (1529) squire of the body, married his sister Jane in 1536, and Edward was created Viscount Beauchamp, and, after the birth of Edward VI., earl of Hertford.

In 1541, during Henry's absence in the north, Hertford, Cranmer and Audley had the chief management of affairs in London; in September 1542 he was appointed warden of the Scottish marches, and a few months later lord high admiral, a post which he almost immediately relinquished in favour of the future duke of Northumberland (*q.v.*). In March 1544 he was made lieutenant-general of the north and instructed to punish the Scots for their repudiation of the treaty of marriage between Prince Edward and the infant Mary Queen of Scots. He landed at Leith in May, captured and pillaged Edinburgh, and returned a month later.

In May 1545 he was again appointed lieutenant-general in the north to avenge the Scottish victory at Ancrum Moor; this he did by a savage foray into Scotland in September. Political and religious rivalry separated him and Lisle from the Howards, and Surrey's hasty temper precipitated his own and his father's ruin.

Protector.—Their overthrow had barely been accomplished when Henry VIII. died. He had no statutory power to appoint a protector, but in the council of regency which he nominated Hertford and Lisle enjoyed a decisive preponderance; and the council at its first meeting after Henry's death determined to follow precedent and appoint a protector. They chose Hertford (now duke of Somerset), and he emancipated himself from the trammels originally imposed on him as protector; he was king in everything but name. In his first parliament, which met in November 1547, he procured the repeal of all the heresy laws and nearly all the treason laws passed since Edward III. Even with regard to Scotland he had protested against his instructions of 1544, and now ignoring the claim to suzerainty which Henry VIII. had revived, sought to win over the Scots by those promises of autonomy, free trade, and equal privileges with England, which many years later eventually reconciled them to union. But Scottish sentiment, backed by Roman Catholic influence and by French intrigues, money and men, proved too strong for Somerset's amiable invitations. The Scots turned a deaf ear to his persuasions; the protector led another army into Scotland in September 1547, and won the battle of Pinkie (Sept. 10).

Somerset apparently thought that the religious question could be settled by public discussion, and throughout 1547 and 1548 England went as it pleased so far as church services were concerned; all sorts of experiments were tried, and the country was involved in a grand theological debate, in which Protestant refugees from abroad hastened to join. The result convinced the protector that the government must prescribe one uniform order which all should be persuaded or constrained to obey; but the first Book of Common Prayer, which was imposed by the first Act of Uniformity in 1549, was a studious compromise between the new and the old learning, very different from the Protestantism of the second book imposed after Somerset had been removed, in 1552. The Catholic risings in the west in 1549 added to Somerset's difficulties, but were not the cause of his fall. The factious and treasonable conduct of his brother, the lord high admiral, in whose execution (March 20, 1549) the protector weakly acquiesced, also impaired his authority; but the main cause of his ruin was the divergence between him and the majority of the council over the questions of constitutional liberty and enclosures of the commons. He was divided in mind between his sympathy with the rebels and his duty to maintain law and order. France seized the opportunity to declare war on August 8; and the outlying forts in the Boulonnais fell into their hands, while the Scots captured Haddington.

His Fall.—These misfortunes gave a handle to Somerset's enemies. Warwick combined on the same temporary platform Catholics who resented the Book of Common Prayer, Protestants who thought Somerset's mildness paltering with God's truth, and the wealthy classes as a whole. In September he concerted measures with the ex-lord-chancellor Wriothesley; and in October, after a vain effort to rouse the masses in his favour, Somerset was deprived of the protectorate and sent to the Tower. But the hostile coalition broke up as soon as it had to frame a constructive policy; Warwick jockeyed the Catholics out of the council and prepared to advance along Protestant lines. He could hardly combine proscription of the Catholics with that of Somerset, and the duke was released in February 1550. For a time the rivals seemed to agree, and Warwick's son married Somerset's daughter. But growing discontent with Warwick made Somerset too dangerous. In October 1551, after Warwick had been created duke of Northumberland, Somerset was sent to the Tower on an exaggerated charge of treason, which broke down at his trial. He was, however, as a sort of compromise, condemned on a charge of felony for having sought to effect a change of government. Few expected that the sentence would be carried out, and apparently Northumberland found it necessary to forge an instruction from Edward VI. to that effect. Somerset was executed on Jan. 22, 1552, dying with exemplary patience and fortitude.

See A. F. Pollard's *England Under Protector Somerset* (1900; full bibliography, pp. 327–339), also his article in *Dict. Nat. Biog.* and vol. vi. of *Political History of England* (1910).

SOMERSET, ISABELLA CAROLINE (LADY HENRY SOMERSET) (1851–1921), English philanthropist, was born in London on Aug. 3, 1851, the eldest daughter and co-heiress of the third and last Earl Somers. She married in 1873 Lord Henry Somerset, son of the eighth duke of Beaufort, from whom she later separated. She was long president of the National British Women's Temperance Association. In 1894 she founded the *Woman's Signal* in the interests of women's work, becoming its editor. She died in London on March 12, 1921.

See Kathleen Fitzpatrick, *Lady Henry Somerset; a Memoir* (1923).

SOMERSET, ROBERT CARR (or KER), EARL OF (*c.* 1590–1645), Scottish politician, younger son of Sir Thomas Ker of Ferniehurst by his second wife, Janet, sister of Sir Walter Scott of Buccleuch. He accompanied James I. as page to England, but being then discharged from the royal service, sought for a time to make his fortune in France. Returning to England he happened to break a limb at a tilting match, at which James was present, and was recognized by the king. Entirely devoid of all high intellectual qualities, Carr was endowed with good looks, excellent spirits, and considerable personal accomplishments. These advantages were sufficient for James, who knighted the young man and at once took him into favour. In 1607 the king conferred on Carr Sir Walter Raleigh's forfeited manor of Sherborne. Carr's influence was already such that in 1610 he persuaded the king to dissolve the parliament, which had shown signs of attacking the

Scottish favourites. On March 25, 1611 he was created Viscount Rochester, and subsequently a privy councillor, while on Lord Salisbury's death in 1612 he began to act as the king's secretary. On Nov. 3, 1613 he was advanced to the earldom of Somerset, in December was appointed treasurer of Scotland, and in 1614 lord chamberlain. Somerset fell from favour in 1615, when the circumstances of the murder of Sir Thomas Overbury in 1613 were disclosed, and he and his wife, who had secured a divorce from the earl of Essex to marry him, were implicated. For this story *see* SIR THOMAS OVERBURY. Possibly Somerset was no more than an accessory after the event. He was pardoned in 1624, and from that time disappears from history. He died in July 1645.

See the article by S. R. Gardiner in *Dict. Nat. Biog.*, with authorities there cited, and the same author's *History of England; State Trials* II.; *Life and Letters of Bacon,* ed. by Spedding; *Studies in Eng. Hist.*, by Gairdner and Spedding.

SOMERSETSHIRE, a south-western county of England, bounded north and north-west by the Bristol Channel, north and north-east by Gloucestershire, north-east and east by Wiltshire, south-east by Dorsetshire, south-west and west by Devonshire. The area is 1,630·3 sq. miles. The county, orographically, consists of a basin surrounded on three sides by hills and limited on the fourth by the sea. The northern hills are the Mendips, composed of Carboniferous limestone, stretching from Nunney to the sea and appearing again in the islands of Steep Holm and Flat Holm, which link the structure of Somerset with that of South Wales. The summit of the Mendips is a long tableland between 500 and 1,000 ft. in height, but rising in the west to just over that figure. To the north they die away gently, as a number of low hills, towards the Avon, which forms the county boundary first with Wiltshire and then with Gloucester. Here the limestone is covered in places by coal measures, but most of the rocks are Triassic. Southward the Mendip hills drop steeply in an abrupt line broken by many coombes, *e.g.*, the gorge of Cheddar. The basin to the south is composed mainly of Triassic rocks, which, near the sea and along the valleys, are covered by recent alluvium. The basin is usually lower in its western than in its eastern part, which is known generally as Sedgemoor, but with different names in different parts. The large basin is subdivided into those of the Parrett and the Brue by the Polden hills, which run parallel to the Mendips from Lydford to Puriton. To the west of the Parrett rise the Quantock hills, which are outliers of the Devonian moorlands of Exmoor and the Brendon hills. These three hill groups consist almost entirely of Devonian rocks, and their highest points respectively are Will's Neck (1,261 ft.), Dunkery Beacon (1,707 ft.) and Lype hill (1,391 ft.). From Crewkerne along the southern and eastern borders of the county as far as the Avon runs a more or less continuous line of low Jurassic hills, while around Chard in the south there is a fair extent of Cretaceous rocks.

In early postglacial times the low lands were morasses and the clay lands forested, and so man, when he came to the district, settled on the open heights—the sterile old rocks of the west, the chalk of the south, the limestone of the Mendips and the oolites on the east—and the caves of Mendip and Cheddar have yielded valuable evidence of late Palaeolithic and Epipalaeolithic cultures. The evidence of finds of weapons, and of tumuli with beakers and other pottery, shows that the distribution of the population in the early ages of metal was very largely on the unforested areas. In the Chew valley, just south of Bristol, a few stone circles show connections with the Megalithic culture, and it is probable that some of the fortified camps date from the Bronze age. At a later time invaders, who knew of iron, penetrated into the county, and we have finds of their weapons, their pottery and of the remains of their animals along with traces of their crops. They had many earthworks here, *e.g.*, Worlebury, north of Weston-super-Mare, at other points on the Mendips, and in the south, at Cadbury; and were the first to settle in the lake-village at Glastonbury (*q.v.*).

History.—The Romans overran Somerset after the Claudian conquest of A.D. 43, and remains of the period of the Roman occupation are numerous, particularly east of 3° W. Bath, which was probably a settlement in earlier times, became, on account of the medicinal properties of its waters, an important Roman centre where the Fosse Way from Cirencester met another road from Silchester. From Bath another road ran north-westward, north of the Avon to the Severn and a Roman station guarded the crossing to Caerleon. The Fosse Way was continued from Bath to Exeter, and on it we have stations at Camerton and at Ilchester, where it crossed the Yeo. Besides these four settlements, remains of about 50 Roman villas have been discovered in the county.

In the 6th century Somerset was the debatable borderland between the Welsh and Saxons, the latter of whom pushed their way slowly westward. Their frontier was gradually advanced from the Axe to the Parrett, and from the Parrett to the Tamar. By 658 Somerset had been conquered by the West Saxons as far as the Parrett, and there followed a struggle between the kingdoms of Wessex and Mercia, which led to the organization of the lands east of the Parrett as part of the kingdom of Wessex. About this time the monastery of Glastonbury was restored by Ine. The next 150 years were the period of Danish invasions. In the 7th century Somerset, as part of the kingdom of Wessex was included in the diocese of Winchester. The new bishopric of Sherborne, founded in 704, contained Somerset until 910 when the see was divided into the dioceses of Salisbury, Exeter and Wells, the latter including the whole county of Somerset. The diocese was divided into three archdeaconries. King Alfred's victory in 878, followed by the Peace of Wedmore, ended the incursions of the Danes for a time, but 100 years later they were again a great danger, and made frequent raids on the west coast of Somerset. At some time before the Conquest, England was divided into shires, one of which was Somerset.

At the Conquest Somerset was divided into about 700 fiefs, held almost entirely by the Normans. The king's lands in Somerset were of great extent and importance; the bishop of Winchester owned a vast property of which Taunton was the centre.

The chief families of the county in the middle ages were those of De Mohun, Malet, Revel, De Courcy, Montacute, Beauchamp and Beaufort, which bore the titles of earls or dukes of Somerset from 1396 to 1472. Edward Seymour was made duke of Somerset in 1547, and in 1660 the title was restored to the Seymour family, by whom it is still held. The marquess of Bath is the representative of the Thynne family, which has long been settled in the county. About this time or a little later many Norman castles were built, some of which have survived.

Somerset was too distant and isolated to take much share in the early baronial rebellions or the Wars of the Roses, and was really without political history until the end of the middle ages. The attempt of Perkin Warbeck in 1497 received some support in the county, and in 1547 and 1549 there were rebellions against enclosures. Disputes between the chapters of Bath and Wells as to the election of the bishop led to a compromise in 1245, the election being by the chapters jointly, and the see being known as the bishopric of Bath and Wells. In ecclesiastical architecture the two great churches of Wells and Glastonbury supply a great study of the development of the Early English style out of the Norman. But the individual architectural interest of the county lies in its great parish churches, chiefly in the Perpendicular style, which are especially noted for their magnificent towers. The churches at Bath, Taunton, Glastonbury, Bridgwater, Cheddar, Crewkerne, Dunster, Ilminster, Kingsbury, Leigh-on-Mendip, Martock and Yeovil may be specially indicated.

Somerset took a considerable part in the Civil War, and with the exception of Taunton, was royalist, the strongholds being garrisoned and held for the king, but they all fell in 1645, and the county was subdued by the parliamentary forces. Somerset was the theatre of Monmouth's rebellion, and he was proclaimed king at Taunton in 1685. The battle of Sedgmoor on July 4 was followed in the autumn by the Bloody Assize held by Judge Jeffreys.

The county was represented in the parliament of 1290, and in 1295 it was represented by two knights, and twelve boroughs returned two burgesses each. The county continued to return two members until 1832, when it was divided into Somerset East and Somerset West, each of which divisions returned two members.

Two additional members were returned after 1867 for a third—the Mid-Somerset—division of the county, until by the act of 1885 the whole county was divided into seven divisions.

Somerset has always been an agricultural county. Grain was grown and exported from the 11th to the end of the 18th century. Cider-making has been carried on for centuries. Among other early industries, salmon and herring fisheries on the west coast were very profitable. Stone quarrying at Hamdon Hill and Bath began very early in the history of the county; and the lead mines at Wellington and the slate quarries at Wiveliscombe and Treborough have been worked for more than a century. Coal has been mined at Radstock from a very remote date, but it did not become of great importance commercially until the county was opened up by canals and railways in the 19th century. Sheep-farming was largely carried on after the period of enclosures, and the woollen trade flourished in Frome, Bath, Bridgwater, Taunton and many other towns from the 14th to the 19th centuries. Glove-making was centred at Stoke and Yeovil in the 18th century. Cheese is made in various parts, notably Cheddar Cheese, which is made on the farms lying south of the Mendips. Sheep-farming is practised both in the lowlands and on hill pastures, Leicesters and Southdowns being the favourite breeds.

Wild deer are still found on Exmoor, where there is a peculiar breed of ponies, hardy and small. The Bristol channel and Bridgwater bay abound in white- and shell-fish; salmon and herring are also caught, the principal fishing stations being Porlock, Minehead and Watchet.

Coal, from the Mendips, and freestone, largely quarried near Bath, are the chief mineral products of Somerset, although iron, manganese, limestone, and slate are also found. The chief manufactures are those of woollen and worsted goods, made in a large number of towns; gloves at Yeovil, Stoke, Martock and Taunton; lace at Chard; linen and sailcloth at Crewkerne; crape at Dulverton and Shepton Mallet. There are large potteries at Bridgwater, where the celebrated bath-brick is made, and at Weston-super-Mare. On the Avon, copper and iron are smelted, while several other rivers provide power for cotton, worsted and paper mills. The bulk of the export trade passes through Bristol, which is situated mainly in Gloucestershire, though it has large docks on the Somerset side of the Avon, and others at Portishead.

Somerset is well furnished with railways. The G.W.R. runs between Frome, Radstock, Bath and Bristol, and from Bristol it curves south-west through Weston and Bridgwater to Taunton, dividing there and passing on into Devon. Branches leave the main line for Portishead, Clevedon and Minehead on the north, and for Witham Friary via Wells, Yeovil via Langport, and Chard via Ilminster on the south. The S.R. main line from London passes through the south-west of Somerset, running from Templecombe to Axminster in Devon, and the Somerset and Dorset runs from Bath to Shepton Mallet via Radstock.

Area of administrative county and associated county borough is 1,036,818 ac.; pop. (1931) 475,120. The county contains 40 hundreds and two liberties. The municipal boroughs are—Bath, a city and county borough, Bridgwater, Chard, Glastonbury, Taunton, Wells, a city, and Yeovil. The county is in the western circuit, assizes are held at Taunton and Wells and it has one court of quarter sessions. The boroughs of Bath and Bridgwater have separate courts of quarter sessions. Somerset is in the diocese of Bath and Wells, excepting small parts in the dioceses of Bristol and Salisbury. There are six parliamentary divisions—Wells, Frome, Taunton, Weston-super-Mare, Bridgwater and Yeovil, each returning one member; while the parliamentary borough of Bath returns one member; and the county includes part of the parliamentary borough of Bristol.

Eyton, *Domesday Studies: Analysis of the Somerset Survey* (1880); F. T. Elworthy, *West Somerset Word-Book* (1886); *Victoria County History: Somerset;* also various publications by the Somerset Record Society.

SOMERSWORTH, a city of Strafford county, New Hampshire, U.S.A., 17 m. N.W. of Portsmouth, on the Salmon Falls river, opposite Berwick, Me. It is served by the Boston and Maine railroad. Pop. (1920) 6,688 and it was 5,680 in 1930. Water-power is abundant, and the city has large woollen and cotton mills. A settlement was established here before 1700.

SOMERVILE, WILLIAM (1675–1742), English poet, whose works include *The Two Springs* (1725), a fable; *Occasional Poems. . .* (1727); *The Chase* (1735) *Hobbinol, or the Rural Games* (1740), a burlesque poem; and *Field Sports* (1742), a poem on hawking. Somervile died on July 19, 1742.

His *Chase* passed through many editions. It was illustrated by Bewick (1796), by Stothard (1800), and by Hugh Thomson (1896), with a preface by R. F. Sharp.

SOMERVILLE, a city of Middlesex county, Massachusetts, U.S.A., on the Mystic river, surrounded by Boston (Charlestown), Cambridge, Arlington and Medford. It is served by the Boston and Maine railroad. Pop. (1920) 93,091 (26% foreign-born white, over half from Canada, England and Ireland) and 103,908 in 1930 Federal census. The assessed valuation for 1927 was $116,406,900. Somerville, originally part of Charlestown, was settled in 1630. The greater part of John Winthrop's "Ten Hills Farm" lay within the present bounds of the city, and here in 1631 he built and launched the "Blessing of the Bay," the first ship built in Massachusetts. For more than a century the region was a sparsely settled farming community and the only manufacturing industry of any importance was brick-making. On a hill in Nathan Tufts park stands a circular building of slate stone (30 ft. high, with a conical cap) originally built (about 1703) for a windmill, and used for a powder house from 1756 to 1822, where Gen. Gage on Sept. 1, 1774, seized 250 half-barrels of powder. In 1775 it became the magazine of the American forces besieging Boston, and Somerville was the headquarters of Nathanael Greene and Charles Lee. On Prospect Hill, on July 18, 1775, Israel Putnam raised the "Appeal to Heaven" flag; and one of the earliest of the continental standards, the Union Jack and stripes, was raised here on Jan. 1, 1776. The opening of the Middlesex canal through Somerville in 1803 and of the Boston and Lowell railroad in 1835 gave an impetus to its growth. It was incorporated as a town in 1842, and in 1871 was chartered as a city. The output of its factories in 1927 was valued at $66,440,533.

SOMERVILLE, a borough of north-central New Jersey, U.S.A., the county seat of Somerset county; on the Raritan river, 36 m. S.W. of New York city, and served by the Central railroad of New Jersey. Pop. (1920) 6,718 (80% native white); 1930 Federal census 8,255. Adjoining it on the west is the town of Raritan (pop. in 1920: 4,457). Somerville is a residential community and trading centre and has a number of factories. There is a fine county court-house (1909) of white Alabama marble, and a large State armory is located here. Among other interesting buildings are the old parsonage of the Dutch Reformed church, built (1750–51) of brick imported from Holland, and the Wallace house (1778), Washington's headquarters while his main army was in camp at Bound Brook. Settlements were made here in the last quarter of the 17th century and the village was at first called Raritan. It became the county seat in 1783, was incorporated as a town in 1863 and as a borough in 1909.

SOMME, a department of France, formed in 1790 of a large part of the province of Picardy (comprising Vermandois, Santerre, Amiénois, Ponthieu, Vimeu and Marquenterre) and a small portion of Artois. Pop. (1926), 473,916. Area, 2,443 sq. miles. It is bounded on the north by Pas-de-Calais, east by Aisne, south by Oise, and south-west by Seine-Inférieure, and its sea-coast extends 28 m. along the English channel. Two streams flowing into the channel—the Authie on the north and the Bresle on the south-west—bound it in these directions. The department is part of the chalk plateau of north-west France, cut by the English channel on the west, with the result that it is seamed by well-marked valleys, showing a succession of terraces which have become classical ground for the student of geology and of palaeolithic man. On the plateau, which rises to about 700 ft. where it approaches the Pays de Bray in the south-west, there are large stretches of *limon,* a fine-grained, porous, fertile material. The Somme is a historic zone of defence of Paris, and the whole district east of Amiens bears the

traces of ceaseless fighting during the war of 1914–18. The river Somme has been made navigable by canalization of stretches. It also supplies considerable power. From Abbeville to the sea its canalized course can take ships of considerable size. From the mouth of the Authie to the Bay of the Somme the coast is lined with sand dunes about 2 m. broad, behind which is the Marquenterre, a tract of 50,000 ac. reclaimed from the sea by dykes, and traversed by drainage canals. The Bay of the Somme, obstructed by dangerous sandbanks, contains the fishing ports of Le Crotoy, St. Valery, which is also the chief commercial port, and Le Hourdel. Next come the shingle banks, behind which the low fields of Cayeux (25,000 ac.) have been reclaimed; and then at the hamlet of Ault begin the chalk cliffs, which continue onwards into Normandy. Near Amiens the Somme is joined by the Ancre from the north-east, the Avre from the south-east and the Selle from the south. The Bresle is a small river south of the Somme, reaching the sea at Tréport.

The department, especially in the north-east, is one of the best cultivated in France. Beetroot for sugar is the staple crop of the Péronne arrondissement; cereals, chiefly wheat and barley, sugar-beet, fodder and mangel-wurzels, oil plants, colza, flax, hemp and potatoes are grown throughout the department. Stock-raising of all kinds is successful.

The chief towns are Amiens (the capital), Abbeville, Montdidier, Péronne, Doullens, St. Riquier, Crécy and Ham (*qq.v.*). Albert (pop. 6,389) is a centre for machine construction; Villers-Bretonneux (pop. 3,542), a centre of hosiery manufacture; Corbie was once celebrated for its Benedictine abbey (founded in the 7th century) the church of which (16th–18th century) is still to be seen, though now ruined. Folleville has a church (15th century) containing the Renaissance tomb of Raoul de Lannoy; Picquigny has the remains of a château of the 14th, 15th and 16th centuries, once one of the chief strongholds of Picardy; Rue has a 15th century chapel; and Tilloloy a Renaissance church.

SOMME, BATTLES OF THE, 1916. This series of battles, or, more strictly, succession of limited engagements, constituted the offensive campaign of the Franco-British armies in 1916. Into it was thrown the entire British effort of the year on the Western Front and such part of the French effort as was available after the exhausting strain of the long defensive "battle" at Verdun (*q.v.*). The genesis of the Somme offensive is dealt with under WORLD WAR.

The original intention had been that the French should play the larger part in the attack, but as they were drained of their strength at Verdun (*q.v.*) so did their share of the Somme plan evaporate. Eventually their front of attack on the Somme shrank from 25 miles to eight and their force from an intended 40 divisions to 16, of which only five assaulted on July 1. From now onward the British were to take up the major burden of the Western Front campaign, and this alone invests the attack of July 1, 1916 with a special significance. Yet the aims of the British commander-in-chief were not reduced in proportion to his resources. His intention was, in the first place, to break the German front between Maricourt and Serre. Secondly, to secure the high ground between Ginchy and Bapaume while the French seized its continuation past Sailly and Rancourt. Next, to wheel to the left and roll up the German flank as far as Arras, so widening the breach. With this aim all available troops, including the cavalry, would drive northwards from the line Bapaume-Miraumont while a converging attack was launched in co-operation against the German front south-west of Arras. Fourthly was to come a general advance towards Cambrai-Douai. If the Higher Command did not visualise quite so rapid a break-through as had been expected in 1915, the conception was of an advance immeasurably swifter and deeper than came about.

Topography.—To understand both the problem and course of the battle a brief description of the ground is necessary, for in few battles did topography have so far-reaching an influence and make so deep an impression on the minds of the combatants. Between Ham and Arras the river Somme runs first from south to north as far as Péronne and then bends sharply to the west, on its way to the sea. From Péronne a low range of hills runs somewhat to the north of west, forming the watershed between the Somme and the basins of the Scarpe and the Schelde. This ridge had fallen into German hands in Oct. 1914 in the course of the operations usually described as "the race to the sea" and the line in this quarter, indeed on the whole front from Arras southward to the Oise, had remained substantially unaltered during 1915, the chief change being that in July 1915 a British III. Army had been formed which relieved the French between the Ancre and the Somme. Subsequently a IV. Army was also formed, and early in 1916 the British had relieved the French X. Army on the Arras front, making their line continuous from Ypres southward. The right boundary between the British and French had varied considerably and in June 1916 was near Maricourt, about 3,000 yd. north of the Somme. Here the Allied line, which southward of this point ran north and south, turned sharply and following the lower slopes of the watershed already described ran west for another 7,000 yd. to make another sharp turn at Fricourt, whence it ran north to and beyond the Ancre, which pierces the ridge between Thiepval and Beaumont Hamel.

German Positions.—The German positions had become extremely formidable. Their defenders had been in undisturbed possession of the high ground for over a year and a half, and since the British had taken over this part of the front the previous autumn, the application of the usual British policy of aggressive trench-warfare had stirred the Germans to strengthen their defences, to develop artificially the advantage of nature. Woods and villages had become fortresses, two elaborate trench systems had been constructed about two to three miles apart, each containing several lines and connected up by intermediate lines or "switches" which greatly complicated the task of the attacker who should penetrate any part of the front. Deep "dug-outs," easy to construct in a chalk country, protected the trench garrisons against bombardment, broad belts of barbed wire obstructed the approaches, the lines bristled with well-placed and protected machine-guns, and every point of tactical importance had been specially fortified. The advantage of the ground for observation lay with the Germans. Masefield in his book "The Old Front Line" expressed the situation aptly: "Almost in every part of this old front our men had to go uphill to attack. . . . The enemy had the look-out posts, with the fine views over France and the scenes of domination. Our men were down below, with no view of anything but stronghold after stronghold, just up above, being made stronger daily."

For an attack on such positions the most elaborate preparations were necessary, both tactical and administrative. Roads and railways had to be made, vast dumps of ammunition and stores formed, gun positions selected and dug, bivouacking and encamping grounds prepared, the water supply expanded. It was not till the end of June that the offensive could be initiated; and it had been practically impossible to conceal from the Germans the scale and nature of the preparations or the intended extent of the attack. Surprise, difficult in face of such commanding positions, was the more difficult because the art of camouflage and of concealing preparation was still immature. Had not the vast preparations given it away, the fact that the bombardment lasted a week would in any case have announced all but the actual day of the attack.

Dispositions.—The British share of the attack was entrusted to Rawlinson's IV. Army of 17 divisions, of which only two, together with 3 cavalry divisions, were in army reserve. In addition a corps of three divisions and the headquarters of a reserve army—under Gough—were placed in the battle area under the hand of the commander-in-chief. Two divisions of the III. Army were to make a subsidiary attack near Gommecourt. The artillery concentration totalled 1,500 guns, averaging one gun to every 20 yards of front, a record at that time, although far eclipsed later. Rawlinson expressed doubts whether it was sufficient but his suggestion that the frontage should be reduced was not acceptable. The bombardment began on June 24, the attack being originally intended for June 29, but subsequently postponed until July 1. This involved not only spreading out the ammunition over a longer period, but a greater strain on the assaulting troops

who, after being keyed up for the effort had to remain another 48 hours in cramped trenches, flooded by a torrential downpour, under the din of the bombardment and the enemy's retaliation.

I. THE FIRST STAGE

July 1, however, dawned dry and with the promise of broiling heat. At 7 A.M. the bombardment rose in intensity and at 7.30 A.M. the British infantry advanced in close-packed waves. These 1916 formations were designed to enable the assaulting infantry to swarm into the opposing trenches as soon as their own guns had lifted. But they exacted a heavier penalty in case of any interval or any insufficiency of the bombardment. And they cramped initiative and hindered the infantry taking sensible advantage of cover—for the infantry were taught to advance at a slow walk in strict alignment. Here the penalty was fully exacted by the stout-hearted and skilful German machine-gunners who, sheltering in dug-outs or shell-holes while the bombardment flattened their trenches, dragged out their weapons and opened fire directly it lifted.

Fricourt, on the right centre, was a turning point not only in the front but in the fortune of the day. All to the north was failure, with the heaviest British loss of any day in the war. On the British left the VIII. Corps attacked from Serre to Beaumont Hamel, but though its centre penetrated some way into the German lines north of Beaumont Hamel the flanks were checked and the central division was finally dislodged. Equal ill-success befell the X. Corps and the left division of the III. Corps to the south, in their attacks on the formidable defences of Thiepval and Ovillers. The right division (the 34th) pressed past La Boisselle to Contalmaison but was forced to fall back, its flank being enfiladed from Ovillers. The next corps, the XV., partially achieved its task of pinching out the bastion of Fricourt village and wood. On its north, next the 34th division, the 21st division gained and held a narrow salient, with both its flanks exposed until Fricourt fell next day. On the other side of Fricourt the 7th division and the XIII. corps (18th and 30th divisions) attacking in a northerly direction were all successful, taking Mametz and Montauban. Beyond them, again, the French astride the Somme fared brilliantly, reaching Hardecourt and Curlu north of the river, while south of it they actually penetrated to and captured six miles of the German second line. They took 6,000 prisoners at little cost.

The Germans had not expected a French attack and were less well prepared on the Fricourt-Montauban front than on the line running north from Fricourt, where both their positions and their fortifications were strongest. The success achieved by the British right and by the French went some way towards compensating for the disastrous failure elsewhere. The Germans could justly claim a victory, for with only six divisions available, and roughly a regiment holding each British division's sector of attack, they had yielded only 1,983 prisoners and a small tract of ground. Yet, although a military failure, July 1 had proved the moral quality of the new armies of Britain who, in making their heaviest sacrifice of the war, came through the ordeal with courage unshaken and fortitude established. These quondam civilians had borne a percentage of loss such as no professional army of the past had been deemed capable of suffering without being incapable of continued action. For five months more they were to continue.

For, on the morrow Haig, realizing the formidable nature of the frontage astride the Ancre, concentrated his attention on exploiting the success of the right—refusing to accede to Joffre's wish for a renewal of the attack on Thiepval. In the course of 10 days of hard fighting in which some six fresh divisions were thrown into the struggle, La Boisselle, Contalmaison and Mametz Wood were cleared and the line was advanced on a front of over six miles to within reach of the enemy's second system of defences on the southern crest of the main ridge.

Second Line of Defence Assaulted.—This system, less strong than that stormed on July 1, was formidable enough and the stubborn resistance of the Germans in their front system and intermediate lines had allowed large reserves of men and guns to be brought up and the defence to be reorganized. If Haig had been unduly ambitious and optimistic before July 14, he now perhaps tended to the other extreme. In contrast the IV. Army command held that in bold and rapid measures lay the only chance to forestall the building of freshly fortified systems in the rear. Rawlinson framed a plan to attack and break the second system on a four-mile front between Delville Wood and Bazentin-le-Petit Wood. His right was still three-quarters of a mile distant. If the obvious course was followed and an attack delivered only on the left, the prospects were barren. For the experience of 1915 had shown that an attack on a narrow frontage might gain an initial success, only to be "blown" out of the captured fragment of ground by the concentration of enemy gun-fire thus facilitated. Rawlinson proposed to cross the intervening and exposed area on the right under cover of darkness and then to attack along the whole frontage at dawn, preceded by a hurricane bombardment of only a few minutes duration.

In 1916 the ideas of a night advance and of such a brief bombardment were so unorthodox as to be a shock and appear a gamble to cautious opinion, especially as it would have to be carried out by troops of the new armies. The commander-in-chief preferred a more limited alternative but Rawlinson persisted, his confidence reinforced by that of the actual troop-leaders in their ability to carry out the night operation. He gained his way, but the debate caused a day's delay which had serious consequences. The attack was delivered by the 9th and 3rd divisions of the XIII. corps on the right and by the 7th and 21st divisions of the XV. corps on the left. Cavalry divisions were brought up close and placed under the two corps commanders.

The hazardous and difficult approach march on the right was successfully carried out and at 3.25 A.M. on July 14, five minutes after the barrage fell, the whole line advanced to the assault. Surprise was achieved, originality vindicated. The whole of the German second system was rapidly overrun. On the right the resistance soon hardened and the 9th division only fought its way with difficulty through Longueval and to the outskirts of Delville Wood. On the left, opportunity—and the open country—stretched out its arms. Soon after midday the German resistance was obviously disintegrating in front of High Wood, and an effort was made to exploit the opportunity. But delay occurred and not until after 6 P.M. did the 7th division move forward afresh, with two squadrons of cavalry working on their flank—the first mounted cavalry seen on a British battlefield since 1914. The second advance, however, was less vigorous than the first and although most of High Wood was cleared, the northern corner and the flanking trenches held out. Worst of all the 24 hours' postponement had enabled fresh German reserves to arrive on the battlefield and as their strength steadily swelled, the German hold tightened, the British relaxed. Late on July 15 the Wood was evacuated under pressure of counter-attacks, and two months were to pass before it was regained. On July 14 the British offensive came within reach of open country and within sight of a strategic decision; thenceforward it degenerated into a campaign of attrition. Two months of hard fighting followed during which the British were unable to make more than very gradual progress at disproportionate cost.

Progress was especially slow on the right, where Ginchy, Guillemont and Falfemont Farm formed a barrier against which many attacks were shattered even after Delville Wood had been won. It was important to extend on this side to get touch with the French who were gaining ground north of the Somme: High Wood in the centre, Pozières on the left, were equal obstacles, and behind Pozières were all the formidable defences of which Thiepval was the centre. Division after division was thrown into the fight, fought desperately, lost heavily and apparently achieved little, though Pozières was taken by the Australians before the end of July. The strain was at last beginning to tell heavily on the Germans: they checked the Allied progress but their resources in men, guns and ammunition were, by Ludendorff's admission, severely taxed and they had to relinquish entirely their attacks on Verdun.

II. THE SECOND AND THIRD STAGES

On Sept. 3 a renewed attack astride the Ancre by the V. Army,

formed from troops taken out of Rawlinson's IV. Army and placed under Gough, was unsuccessful, but the IV. Army on the right at last mastered Guillemont and in the next few days added Falfemont Farm, Ginchy (Sept. 9), Leuze Wood and Bouleaux Wood to its gains, while the French made substantial progress north of the Somme and gained a big success south of it, taking 7,000 prisoners and storming three m. of the old German front line as far as Chaulnes. These successes removed the main obstacles to the advance of the British centre, freeing it from the menace of being enfiladed.

Haig thereupon planned a big spring forward for Sept. 15, second only in scale and ambition to July 1. The attack was to pivot on the left wing—Gough's Army. The object of the main blow, by Rawlinson's IV. Army, was to break through the Germans' original last line between Morval and Le Sars, in co-operation with a French thrust to the south between Combles and the Somme—"pinching out" Combles. If the opening success warranted the attempt the attack was to be extended on the left to seize Courcelette and Martinpuich. Eight divisions were deployed for the original attack, and two detailed for the "extension." A special feature was the employment for the first time of tanks (*q.v.*), the armoured cross-country machines which had been invented as an antidote to the defensive obstacle of machine-guns and barbed wire. In disregard of the opinions of the tank's progenitors, and of their own expressed agreement with these opinions, the British Higher Command had decided to utilise such machines as were available, to redeem the fading prospects of the Somme offensive. When this decision was taken only 60 of the initial 150 machines had been transported to France. Forty-nine were actually employed, to work in tiny detachments of two or three machines—another breach of the principles laid down by Colonel Swinton (*q.v.*). The rushed preparation combined with the mechanical defects of these early models to reduce the total, so that only 32 reached the starting point. Of these, nine pushed ahead with the infantry, nine failed to catch the infantry but helped in clearing the captured ground, nine broke down and five were "ditched" in the craters of the battlefield. The first nine rendered useful aid, especially in capturing Flers, but the greater prize of a great surprise stroke thus lost was a heavy forfeit to pay for redeeming in a limited degree the failure of the Somme offensive.

The attack was launched at dawn on the 15th in a slight mist, and the XV. corps in the centre made early and good progress, and by 10 A.M. its left division was beyond Flers. But on the right the XIV. corps lost heavily and was held up long before it could reach Morval and Lesboeufs. The III. corps, on the left, also fell short of its objectives, although its 47th division finally cleared the long-sought High Wood. On the extreme left the projected "extension" of the attack was carried out and both Martinpuich and Courcelette were taken. As a result of the day the crest of the ridge had been gained, except on the right, and with it the commanding observation which the Germans had so long enjoyed. A fresh attack on Sept. 25, swept over Morval, Lesboeufs and Gueudecourt and by joining up with the French who had again secured substantial successes both north and south of the Somme, compelled the Germans to evacuate Combles (Sept. 26).

Simultaneously with this success operations were resumed by the V. Army on the British left and Thiepval was at last taken (Sept. 26). This left the Germans with only the scantiest foothold on the main ridge. Thus by the beginning of October the enemy had been driven back to his last completed line of defences, which ran from Sailly-Saillisel on the right, past Le Transloy and in front of Bapaume: he was busily engaged on fresh lines further in rear but as yet these were unready. On the other hand, these days had proved the continued strength of the German resistance, and the limited success held out little hope of a real breakthrough or its exploitation. The early onset of the autumn rains daily made this hope more slender. Continuous and heavy rain combined with the effects of the bombardments to make the ground a sea of mud, across which guns and transport could hardly be moved, and even lightly equipped men could only struggle slowly forward. Attacks under such conditions were terribly handicapped; that most of them failed was not remarkable, for when a trench was taken the difficulties of consolidating it were greater than ever. Eaucourt l-Abbaye (Oct. 3) and Le Sars (Oct. 7) were taken, though repeated attacks on the Butte de Warlencourt were foiled by the mud. Eventually the weather improved enough for a renewal of the attack on the left and the last important operation in the Somme offensive took the shape of an attack on Beaumont Hamel by seven divisions on Nov. 13. This proved successful on the right and centre, taking Beaumont Hamel itself, and Beaucourt-sur-Ancre with 7,000 prisoners. On the left, however, Serre again proved impregnable. Before the success could be expanded the return of bad weather again put a stop to active operations, which were not resumed on any considerable scale until well after the New Year, just before the carefully planned German retreat to the Hindenburg line. The folly of the third phase was that having at last won the crest of the ridge and its commanding observation, the advantage was thrown away, without adequate prospect of compensation, by fighting a way down into the depression beyond. Thereby the British troops were doomed to spend the winter in flooded trenches, and the battles of the Somme closed in an atmosphere of disappointment and with such a drain on the British forces that the coincident strain on the defence was obscured. For the fighting sometimes known as the second battle of the Somme, *see* ST. QUENTIN, BATTLE OF, 1918.

SOMMER, SUMMER or **SUMMER BEAM,** in architecture, a girder or main beam of a floor; if supported on two storey posts and open below, it is called a *bress* or *breast-summer.*

SOMNAMBULISM or **SLEEP-WALKING,** the condition under which people walk while asleep, apparently unconscious of external impressions, return to bed, and when they awake have no recollection of any of these occurrences. Sometimes the actions performed are of a complicated character and bear relation to the daily life of the sleeper. Frequently somnambulists have gone along dangerous paths, executing delicate movements with precision.

Somnambulists may: (1) speak without acting, common in children and not usually considered somnambulistic; (2) act without speaking, the most common type; (3) act and speak, more exceptional and (4) act, speak and have the senses of touch, sight and hearing. The fourth class merges into hypnotism (*q.v.*).

It should never be forgotten that somnambulism is an indication of a nervous disposition requiring careful treatment so as to avoid more dangerous maladies.

SOMNATH, an ancient decayed city of Kathiawar in the province of Bombay, India. Pop. (1921), 6,867. The city was most famous for the temple just outside its walls in which stood the great columnar emblem of Siva called Somnath (Moon's lord), which was destroyed by Mahmud of Ghazni. The famous "Gates of Somnath," which were supposed to have been carried off by Mahmud to Ghazni are now in the arsenal at Agra.

SOMNUS, Sleep, the son of Night and the twin brother of Death, with whom he dwells in the darkness of Hades. In Ovid (*Metam.*, xi. 592) the home of Sleep is placed in a dark grotto in the land of the Cimmerians, where he dwells surrounded by a band of Dreams.

See Homer, *Iliad*, xiv. 231 to xvi. 672; Hesiod, *Theog.*, 212, 758; Pausanias v. 18, 1.

SOMOV, KONSTANTIN ANDREEVICH (1869–), Russian painter, was born in St. Petersburg (Leningrad), Nov. 30, 1869, his father being director of the Hermitage Museum. Early in his career he worked under Ilia Repine, the realist painter and professor of the Academy of Arts. He was greatly influenced by the masters of the "Fêtes Galantes" and by the art of Aubrey Beardsley and Charles Conder. Somov was one of the founders of the group known as "The Artistic World." In 1919 he issued *The Book of the Marquise*, which he illustrated with a number of

characteristic drawings. His best portraits, which are drawn in coloured crayon, show remarkable delicacy of execution and masterly delineation of character. Somov, who was a connoisseur of ceramics, also produced a number of groups painted on china. *See* Oscar Bie, *Constantin Somoff* (1907).

SONANCE: *see* VOICE.

SONATA, in music, originally a piece "played" as opposed to "cantata," a piece sung. By the time of Corelli the term had come to mean a group of instrumental movements. (A movement is a piece of music forming or starting as if to form, a complete musical design.) The sonatas of Corelli are classified as *sonata da chiesa* (church sonata) and *sonata da camera* (chamber sonata). Both kinds were usually for one or two violins with *continuo* bass (*see* CHAMBER MUSIC and INSTRUMENTATION). Handel, when a boy, wrote six for two oboes, and in later years several for flute, and also for one oboe.

The *sonata da chiesa* consists typically of a slow introduction, a loosely fugal allegro, a cantabile slow movement and a lively finale in melodic "binary" form (*see* SONATA FORMS). The *sonata da camera* consists mainly of dance-tunes (*see* SUITE). Bach, who uses neither title, keeps the two kinds unmixed in his six sonatas for violin alone, the first, third and fifth being *sonata da chiesa* and the others *partitas.* A fusion of the two styles persisted in Italian violin music almost to the end of the 18th century.

The sonatas of Domenico Scarlatti (*q.v.*) are small harpsichord pieces, of which the best known are extremely brilliant single movements in binary form. The complete collection of 545, published by Longo, shows that Scarlatti experimented audaciously in remote modulations; that he also wrote some orthodox violin sonatas; and that he sometimes followed a lively movement by a slow cantabile, as Paradies did in his sonatas. Clementi's early sonatas are at their best when they resemble a sober and heavy-handed Scarlatti in a first movement which maintains a uniform rush of rapid motion; and Mozart has left a fine example of the kind in the first movement of his F major violin sonata (K 377).

The main classical sense of the term indicates a work for not more than two instruments, containing at least two, and in the complete scheme, four well-contrasted movements, of which the first and last are on the same tonic, and the others in demonstrably related keys (*see* HARMONY, sec. 5); the forms being those dealt with in the following article. (D. F. T.)

SONATA FORMS, in music. The sonata forms (*see* SONATA above) cover the whole ground of instrumental music from C. P. E. Bach to the advent of Schumann's pianoforte lyrics and Liszt's symphonic poems, and are still living forms. Their rise made Gluck's reform of opera possible; for they represent a general change in the language of music which made it a truly dramatic medium. They comprise the largest and most central problems of pure music; and the outward forms must be studied in constant connection with instrumentation, harmony, melody, counterpoint and rhythm (*qq.v.*).

Elements of Form.—Two types of form are externally common to the true dramatic sonata style and the earlier melodic forms used in the suite (*q.v.*). The terms *binary* and *ternary* have been chosen for these; and, as we shall see, badly chosen. A binary melody falls into two portions, of which the first ends away from tonic, and the second ends on the tonic. *Barbara Allen,* quoted in the article MELODY, is an exquisite example on the smallest possible scale. A ternary melody, such as *The Bluebells of Scotland,* has a complete first clause, a second clause not as complete, and a third clause consisting of the first over again; a form conveniently symbolized as ABA.

No view of music can be correct that neglects the fact that it moves in time; though a composer may develop Mozart's capacity for seeing music spatially, *i.e.,* like a picture, all at once. Now, when do we know that a melody is going to be "ternary"? Obviously when its first clause has shown itself to be complete. If the sequel refuses to divide itself according to a "ternary" rule the ear is not going to reverse its judgments merely because we have chosen a bad term of classification. After the first clause, anything may happen. The rest of the tune may be no longer than the first clause. All that we can expect of it is that it will cover a wider ground than the first clause, even if in fewer notes or in less time. But this is not all. Every tune of several clauses lends itself to repeating its sections. Binary tunes repeat their two sections. Does a ternary tune repeat its three sections? Try the experiment on the very typical ternary theme of the variations in Beethoven's Kreutzer sonata. Play the first clause with its repeat and try repeating the second clause before returning to the first. You will hardly have the patience to finish the experiment. It will at once reveal that under the test of repeats our "ternary" melody is not ABA but A, BA.

Ex. 1

Thus while both these forms divide only into two repeatable portions the one named "binary" has an incomplete first part while the first part of the other is complete. Our pundits would make musical terminology less misleading if they would kindly find Greek or Latin names, not longer than the forms themselves, that should express "form-with-an-incomplete-first-part" on the one hand, and "form-with-a-complete-first-part" on the other. Clearly the distinction is that between higher organizations and lower, or sectional, forms. From the so-called binary form originates the sonata-form *par excellence,* that of the first movement of a sonata. From the so-called ternary form originate all those sectional forms of music that begin with a complete symmetrical melody, however many sections the form may eventually develop. Thus the "ternary" type underlies the *rondo* (*q.v.*).

The Sonata Style.—Sonata form represents a style that is evident in every bar from the outset, however its themes may be distributed. We are told that the binary form of a dance-movement in a suite has a polyphonic texture and a single theme; and that Philipp Emanuel Bach created the true sonata form by inventing the "second subject." Good teachers make sure that their pupils understand that the "subject" of a sonata is not a single theme, like the subject of a fugue; but in spite of all precautions a host of bad musical forms and crooked musical doctrines have grown up from the provincial fact that English musicians have fastened on the terms "first" and "second subject" instead of translating the excellent German terms *Hauptsatz* (principal member) and *Seitensatz* (subordinate member).

Some of Sebastian Bach's most typical gigues have at least two distinct themes, while more than one of Haydn's ripest sonata movements derive everything from their first themes. Accordingly we may illustrate the true distinction of style by examples which refute superficial doctrines.

These two examples are almost exactly the same length, yet

Haydn is beyond Bach's scope in the first eight bars. If Bach could have accepted so trite a theme as Haydn's, he would have postulated that it did not end with a bump: and bars 5–8 would have horrified him, for he would have supposed that a movement that began so vulgarly was condemned to continue in the same style. Bar 8, however, enters on matters that Bach had never known. In it the first bar of a new period overlaps with the last

Ex. 2. Bach. Gigue from 3rd Suite for Violoncello

bar of the old; and therewith we are plunged into a polyphony quite lively enough for Bach, and quite unpredictable in rhythm and key, its fourth bar overlapping with the answer in A minor, and the viola and violoncello entering in F major at intervals of two bars. Then, arising from bar 18, there are four bars on the dominant of F, with that merely jingling figure (c). We need not set limits to Bach's intelligence, and we may suppose that such a composition would have convinced him that here was no trivial *divertissement,* as he called the non-polyphonic sonatas that were becoming fashionable in 1745, but a new art with enormous possibilities.

Bars 23–26 transform the two notes of (a) into rich sustained harmonies. Then figure (b) bursts out in a new type of phrase, built up in 3-bar periods, which the ear need not trouble to recognize as such in the general bustle. The third of these periods abandons the figure and makes a melodious close into 5 bars of cadence on figure (b) with upper notes that merge into (c), nicely phrased. It is idle to say that all this has more than one theme, and worse than idle to deny that Bach's gigue has at least two distinct themes, that of the beginning, and that in bars 29–36. But Bach's relatively uniform texture will tolerate neither interruption nor irregularity of rhythm.

Haydn's exposition groups itself clearly into bars 1–8, the first group (*Hauptsatz*), asserting the tonic and overlapping with bars 8–22, which effect the transition (plus the sustained chords 23–26) to the second group (*Seitensatz*) in F major, bars 27–40, with its cadence-phrase (*Schlussgruppe*) in bars 36–40. These sections could not be more distinct with any number of themes.

There are no rules whatever for the number or distribution of themes in sonata-form. When critics tell us that Mendelssohn is weak "in second subjects, where the human element is required," they disqualify themselves by a terminology as useless as that of the friend who did not see where the painter was going to put his brown tree. Any generalized criticism of sonata themes is bound to be nonsense; for themes stand in endless variety of relation to the whole. They are details, which give pleasure in themselves as well as in their relation to the scheme. But it is foolish and vexatious to lay down rules as to what pleasure the details shall give. If you examine frescoes with a microscope or miniatures with a telescope you will not enjoy them; and if you expect Beethoven's "Harp" quartet to show you the purport of its first movement in its themes you might as well try to study foreign poetry through a traveller's phrase-book.

So much, then, for the vital element of drama in the sonata. Historically it originates wholly with Haydn and Mozart; and Philipp Emanuel Bach contributed to it nothing but a romantic rhetoric. His chief pride was in his invention of *Sonaten mit veränderten Reprisen;* that is to say sonatas in which the repeats were written out in full in order to control the fashion of altering and amplifying the ornaments on repetition. Now, could anything more clearly betray a non-dramatic style? The survival of repeats in the most dramatic works of Beethoven and Brahms shows how powerfully an architectural symmetry can dominate a series of emotional tensions: but imagination boggles at the thought of using these repeats to display a new set of ornaments.

Haydn saw that the only place for C. P. E. Bach's device was in purely lyric slow movements. Even there he never had the patience to plod and pose (as C. P. E. Bach did to the bitter end) through a repetition of both parts. When his second part comes to recapitulate the second group it combines both versions. This form appears for the last time in history in one of Haydn's "London" symphonies, in the wonderful movement of which the theme is quoted in Rhythm, Ex. 1. Though "binary" it is manifestly lyric, and could no more be applied to active movements than the Spenserian stanza could be applied to drama.

A more important step toward the true sonata style was made by Philipp Emanuel's less romantic brother, Johann Christian, who settled in London, founded the Bach and Abel Concerts, and had a great influence on the boy Mozart. J. C. Bach is the first composer to lay a dramatic emphasis on the transition between his first and his second group. In crude or deliberately formal examples this has been wittily described as "presenting arms" to the new key. Its point is not that there is any difficulty in apprehending the new key, but that the move into it is dramatic and not decorative. Whether the move be made with intellectual music or with common forms makes no difference. Beethoven preferred, in his most characteristic early works, to disguise it cleverly. In later works he acquired the grand formal breadth of Mozart's chamber-music in this transition.

First-movement Form.—The general scheme of the first-movement form or, *par excellence,* sonata form, is as follows. There is a first group in the tonic, followed by a transition to another key, where there is a second group that usually ends with a neat little cadence-theme. These groups constitute the exposition, which may be repeated. Then follows the development, the function of which is to put the previous materials into new

Ex. 3 Exposition in sonata style

lights, regrouping the figures into new types of phrase, modulating freely and settling, if at all, only in new keys. Eventually a return is made to the tonic, and so to the Recapitulation. This recapitulates the exposition, but it gives the second group in the tonic, and so completes the design. The development and recapitulation may be repeated; a coda may follow the recapitulations.

This account has required so many words that the illusion is apt to arise that it conveys more information than, say, the statement that the plan of a cathedral is cruciform and that the arms of the cross are called transepts, and so on. It gives us no means of distinguishing an ambling decorative movement by Boccherini from the first movement of a Beethoven symphony; and the description of the development is the only point which would rule out the sequel of our second example as a specimen of sonata-form. Haydn, Mozart and Beethoven differ widely in their handling of every part of the scheme.

The most regular form is to be found in Mozart, whose transitions are always broad and smooth. The effect of "presenting arms" is evident only in small or perfunctory works; and if it is found at all in larger works it is on such a scale and with such a purpose as Beethoven would give it. The second group contains at least one definite new theme and a number of cadence-phrases in various rhythms. The development is short, consisting of one broad sequential process that leads through a wide range of keys back to the tonic. Sometimes it contains an entirely new theme. Such an episode, which is generally placed at the beginning, by no means always indicates a lighter style and texture. It may be a relief from unusually concentrated figure-work in the exposition; and the developments of two of Mozart's most serious works (the C minor serenade for 8 wind instruments, better known as a string quintet, and the G minor pianoforte quartet) are episodic. The return to the tonic always has the effect of being accurately timed after a delightful period of anticipation.

The recapitulation is full and has a deceptive appearance of regularity. In reality it is anything but mechanical. It has just that kind of difference by which stereoscopic pictures produce the effect of binocular vision. In the light of the recapitulation the listener finds that points that were superficial in the exposition have now become solid. The composer instinctively conceives his exposition in relation to the question "How will this sound when it returns?" The minimum change happens automatically with the transition to the second group, for this transition must no longer lead to the complementary key of the exposition. One quaint primitive device in the transition is that of making it not leave the tonic at all but simply come to a pause *on* (but not *in*) the dominant. This dominant is then taken literally as a key. In such a case the recapitulation need alter nothing; the second group merely follows in the tonic instead of in the dominant. Even this automatic device makes the recapitulation give a more solid impression than the exposition; for the pause on the dominant, treated paradoxically in the exposition, is now treated rationally.

We need not deny that formal devices are apt to become mechanical; but we have no right to the *a priori* opinion that Mozart is writing unimaginatively every time that he decides that

the most familiar course is the wittiest. It is much wiser to regard the most exact recapitulation as the extreme case of delicate balance, and even in the most exact the crucial detail will appear. Here is a case in a difference of a single bar, Mozart's string quartet in E flat (K. 428) has the following clause in the first theme:

Ex. 4

In the recapitulation you have this—

Ex. 5

The little comment of the second violin is expanded and made to turn the following "added 6th" chord into a momentarily solid supertonic key. Similar points make the recapitulation of the second group also stand out in higher relief. Most interesting of all are the ways in which Mozart in a minor movement translates the second group from the major into the minor mode. It is worth while trying the experiment of literal translation (not always an easy task) and then seeing what Mozart has done in such cases. For codas Mozart either finds a slight expansion in the recapitulation of his second group adequate, or else he adds a neat final paragraph. If the development contained an episode Mozart's coda may allude to it. In the finale of the so-called "Jupiter" symphony he uses the coda for his quintuple counterpoint on all the five themes of the movement. (*See* COUNTERPOINT.)

Haydn's practice in his later works differs from Mozart's in almost every particular. His second group often contains no new theme until the cadence-group at the end; his development is long and divisible into several stages, often including an illusory early return to the main theme in the tonic followed by a new excursion into remote regions; and as to recapitulation, the term is seldom applicable at all. The first theme, indeed, returns, but it is followed by a brilliant peroration full of new developments and giving the repose of recapitulation only in the fact that it remains firmly in the tonic. If after such a peroration Haydn chooses to end quietly and abruptly with his cadence-theme, the effect is witty. But it does not make him a formalist. He is a master not only of form but of spaciousness in the smallest possible compass. One main theme for both groups gives him more room for expansion than two; and instead of saying that his recapitulations are free we ought to say that he invented the most brilliant type of Beethoven's coda. And these features of his form are not, as has sometimes been alleged, primitive. They are only partially visible in quartets before Op. 50. Then they appear in full vigour, and Haydn's admiration for Mozart only confirms him in his independence.

Mozart's more symmetrical form is a function of two things, a more polyphonic style and a larger scale. We may sum up the relation between Mozart's form and Haydn's thus: that in Haydn we are aware of an expansive freedom which proves, on scrutiny, to have an all-pervading sense of proportion; while in Mozart we are aware of beautiful and symmetrical proportions which prove on scrutiny to be handled with an all-pervading freedom.

Beethoven combined the forms of Haydn and Mozart, writing on a scale large enough to contain Mozart's regular recapitulations together with Haydn's free perorations, and developing a tragic power all his own. Such new power was not to be obtained without a new technique. A passage from Haydn and one from Beethoven, may be chosen to show how Beethoven set to work. In the first movement of Haydn's A major quartet (op. 20, No.

Ex. 6

6) the second group has been duly ushered in by a highly-organized transition passage and has already started a new theme. This, however, comes to a pause on the dominant, and then we have the following modulating themes—Ex. 6. The harmonic colour of these keys is delightful, and their mutual relations are of direct importance. The passage is improvisatorial and ruminating. Its modulations are within the local range of its start in E minor, and its windings only confirm the drift towards E major. Without them the passage would lose its freedom: with wider modulations it would lose coherence.

Now take the opening of the second group in the first movement of Beethoven's sonata, Op. 2, no. 2. Here is its skeleton outline—

Ex. 7

To analyse the enharmonic modulations and keys (including the unrelated $\flat$V) of this passage is, in Kingsley's admirable parable, like making an exhaustive chemical analysis of a plum-pudding and omitting to ascertain that the cook had boiled it in a cloth. The gist of the matter is the steadily rising bass, with its accelerated later steps and the profound psychology of its pause for 8 bars (after the quotation) before plunging into the final codential steps G♯, A and B, in widely different octaves. This is one of the epoch-making passages in musical history. Its importance does not lie in its wonderful enharmonic modulations. These could not in themselves have achieved more than had been already achieved by C. P. E. Bach: for without the rising bass their purpose would be merely to astonish and not to construct. But with the rising bass and similar resources the whole art of tonality expands. This soon enabled Beethoven to choose remoter keys for his second group. (*See* Harmony, section 5.)

Ex. 8 gives the outline of the first movement of Beethoven's "Eroica" symphony. Blank bars indicate the continuance of a harmony. They are often without theme, and are the lungs of the organism. Quaver-bars or other rhythmic indications above the line indicate the prevalent movement in accessory parts, whether contrapuntal or homophonic. Fine detail is not indicated, and short passages marked as repeated may be assumed to be rescored often beyond recognition. The outline, however, gives a comprehensive summary of the structure of this highly significant movement, and by means of it the reader will be enabled to apprehend, almost at a glance, the inexhaustible expansive and contractile power of Beethoven's phrase-rhythm. Nine conductors out of ten overlook the first theme of the second group entirely, but it is the one constant element in all Beethoven's dozens of sketches.

Freedom in a recognizable recapitulation can go no further than the marvellous modulations with which Beethoven transforms the first group; and anybody inclined to cavil at the exact recapitulation of no less than 100 bars comprising the transition and second group, may be surprised to learn that this is, by the clock precisely the same length as Isolde's Liebestod (*vide* Rhythm) and that in the Liebestod Wagner exactly recapitulates, without transposition, the last movement of the love-duet in a previous act. Recapitulation is as inveterate in musical form as symmetry is in architecture; and nobody understood this better than the first and most uncompromising realist in the application of music to drama.

Other Movements.—A thorough understanding of the style and methods of first movements makes all the rest easy. As to slow movements, the first thing that must be realized is that if a theme conceived in an average quick tempo be played four times as slow it will take four times as long. Some composers, and even some teachers, do not seem to have learnt this remarkable fact. In the music of a master slowness means bigness. The first 16 bars of the slow movement of Beethoven's D minor sonata (Op. 31, no. 2) look like, and are, a single binary sentence closing into the 17th bar. But the all-seeing eye that takes this in at a glance many miss the important fact that that binary sentence takes a whole minute by the clock. Quavers at 96 is a very good metronome-tempo for this movement, and it gives exactly 16 of those bars to a minute. The metronome at 72 to a bar gives a good, moderate tempo for the finale. Now, see how far one minute takes us in the finale. The simple binary first sentence of the adagio takes as long as the two closely-printed pages from the beginning of the finale to the middle of its cadence-theme! Thus in the slow movement of Beethoven's fourth symphony (another case of 16 bars to the minute) the 15 bars beginning in E flat minor and dwelling in G flat (bars 50–64) are a very spacious development; and so are the 7 bars in the middle of the slow movement of the trio in D major, Op. 70, no. 1. Such passages are ample developments if they modulate widely and contain important changes of rhythm, instead of merely dwelling on the dominant before the return of the main theme as in the slow movement of the D minor sonata.

No wonder that in any movement slower than *andante* the full sonata form is unusual and of gigantic effect. The full-sized rondo-form (*see* Rondo) as in the case of the fourth symphony just mentioned, is still more voluminous in a slow tempo. Movements of more normal size may be in A, B, A form, or sonata-form without development (Mozart's favourite form); or may consist of a theme with five or six variations and a short coda. Haydn's form of variations on two alternating major and minor themes is sometimes used by him in slow movements, and sometimes (in small works) as the first movement or as finale. (*See* Variations.)

The finale is often in first-movement form, but will, in such cases, have a much simpler texture. The last part of a work that moves in time will always relieve the strain on the attention. Hence the large number and importance of rondo-finales; and hence the paradox that both Haydn and Beethoven found the fugue an excellent form for a finale. For the fugue, while continually stimulating and exercising the mind by means of details, makes no claim on the listener's memory over long stretches in a major composition.

The first movement, slow movement and finale have thus an unlimited dramatic scope. A purely lyric or dance movement added to such a scheme would in itself be dramatic by contrast, as a song may be a dramatic element in a play. This justifies the dance-form of the Mozart-Haydn minuet and trio, of which Beethoven accentuated the dance-character when he expanded it to the scherzo (*q.v.*). Haydn's very earliest minuets show an inveterate irregularity of rhythm which stamps them even sooner than his other movements, as dramatic. Mozart's minuets are smoother, but he can pack operas into them without bursting the bounds of melodic forms. The minuet of his E flat quartet, for example (K. 428), has five distinctly expressed themes; and its trio, which in contrast has only one theme, moves, however, in four distinct new keys.

The Sonata as a Whole.—The full scheme of a sonata consists, then, of these four movements, the minuet or scherzo being either second or third. Two movements, suitably contrasted, will make a sonata, even if (as in Beethoven's Op. 54) neither of them is in full first-movement form. But it is exceptional for a mature work to claim the title of sonata on merely lyric forms. And in

*The allusion is probably intentional as Beethoven had great difficulty with those introductory bars. At all events he found that their proper shape was that of final bars.

the case of quartets, the feeling of the classical masters is that when so many as four players are assembled it is a waste of opportunity to give them less than a four-movement work to play.

Why do the classical sonatas maintain this scheme of self-centred movements with no community of theme? The answer to this lies in the relation between their time-scale and their emotional content. In its early forms the sonata is a new kind of suite, complete in its contrasts. In its later developments the individual movements, while complete as designs, raise emotional issues which each movement is unable to satisfy without the others. The first movement of Beethoven's not inaptly named *Appassionata* sonata (Op. 57) whirls us through an immense tragedy in eight minutes. The movement is irrevocably completed; but our emotional reactions have not more than begun. We need the unutterable calm of the slow movement with its theme rooted to its tonic chord, and its simple and solemn variations in the ancient form of *doubles*. A foreign chord replaces that of its cadence; the vision is broken and the finale rushes headlong to the end of a tragic fate. The whole emotional scheme is perfect; but for one movement to take up the themes of another would be to tell a twice-told tale. Hence the classics, including Brahms, are not only cautious but cryptic in the few cases where they allow one movement to allude to another. The only occasion for clearness in such allusions is with introductions, which may well foreshadow the following movement, and, in the case of introductions to finales, may dramatically recall the past.

The emotional unity of the sonata is already significant in Mozart and Haydn. Their artistic hypotheses are those of comedy; and even so tragic a note as the last page of Haydn's F sharp minor quartet (Op. 50, no. 4) can be sounded only in the severe form of fugue. One of the most significant gestures in all the history of music is that of the introduction to the finale of Mozart's G minor quintet. The slow movement is one of the profoundest things possible before Beethoven. One is inclined to resent the notion that such music can have limitations. Being perfect it is infinite, and you cannot compare infinities. But you can be clear as to their elements; and the terms of its art forbid this pathetic music to handle tragic action. For tragedy, music needs such resources as are shown in Ex. 7, and these would shatter Mozart's aesthetic system. But after that slow movement even the finale of Mozart's own G minor symphony would sound peevish. So Mozart writes a solemn slow introduction which bids the art of music run away and play, for the rest is too sad for it. And so the bright rondo-finale is another story. Mozart would neither violate his aesthetic system nor anticipate Mendelssohn's naïve way of striking a religious note with a complete unconsciousness of its blasphemy.

The Sonata Since Beethoven.—The sonata-style belongs to the sonata time-scale and to the classical key-system. Music in the Wagnerian time-scale, or in "atonal" or other new harmonic systems, has no more to do with it than Greek prose. Nor do changes in the general outlines of the form mean much in themselves. The classical forms are, even externally, far more varied than those of later sonata-works; and the essentials of the sonata lie much deeper.

Schubert achieved wonderful things in his sonata works, but died before he had perfected his forms. His expositions digress into developments, his developments subside into long twice-repeated lyric episodes, and his recapitulations reveal that recapitulating is the very thing his expositions are not designed to bear. Nevertheless Schubert was on the high road towards genuine new forms.

What these forms were to be was best revealed by Brahms. It is fashionable to deny that Brahms invented new forms; and this is like Humpty-Dumpty's complaint that Alice's features were arranged so exactly like other people's that he could not be expected to recognize her. Forms must be studied in detail from phrase to phrase, and classified afterwards: not classified by guess-work and warped to fit the guess. Brahms has many new ways of phrasing and of developing themes (*see* Melody, Ex. 11); and no two of his forms are alike. Least of all composers does he resemble Schumann, whom he was at first accused of imitating.

Schumann's sonata works show an interesting artificial system. His ideas were lyric and epigrammatic; and they shaped themselves squarely and with a Macaulayesque habit of antithesis. With this style he contrived to build important sonata works as one might construct a landscape in mosaic. He knew what he was doing, and the result is often delightful. In his D minor symphony he achieved a new continuity of form and theme, retaining the classical group of four main movements, but running them together without break and using transformations of the same themes in all four. Schumann's hard outlines and square rhythms have been copied without his wit in countless later sonata works, especially by those Russian composers who, led by Nicolas Rubinstein, danced upon his grave in derision of these very features.

Mendelssohn handled all sonata forms with an often dangerous facility but sometimes with genius. The opening of his D minor trio is the prototype of those innumerable allegros which are really andantes riding an ambling horse or running up a descending escalator.

The masterly scheme (there is only one) of Spohr is (as Schumann remarked) not so easy to imitate as it looks; but it is the prototype of most pseudo-classical works up to the present day; and many teachers believe it to be the only orthodox form. Against such teaching young artists do well to revolt, but why call it classical?

The quality most conspicuously absent in sonata-work since Brahms is movement. The fundamental mistake of Bruckner (*q.v.*) was in associating his Wagnerian style with sonata forms at all. Sibelius solves Bruckner's problem, and takes and leaves the sonata style as he pleases, and always with clear purpose, whether convincingly or not. Reger's meticulously regular forms are hard to accept as the really proper vessel for his strong chromatic brew; and as for imitating him, one might as well try to write a Meredith novel from one metaphor to the next. The art of movement is the crux of the sonata problem; and the classical solutions of it from Haydn to Brahms are the greatest things in pure music.

(*See* also Symphony; Sonata; Music; Variations; Rondo; Scherzo; and the articles on the various individual composers who have been referred to.) (D. F. T.)

SONDERBORG, a seaport and seaside resort in North Slesvig, Denmark, on the south-west coast of the island of Alsen, of which it is the chief town, and 17 m. N.E. from Flensburg. Pop. (1925), 10,454. The town, which existed in the middle of the 13th century, was burnt down in 1864 during the assault by the Prussians upon the Düppler trenches. It then passed into the possession of Germany, but was restored to Denmark by the plebiscite of 1920. It is connected with the mainland by a pontoon bridge, and has a castle with a beautiful chapel.

SONDERSHAUSEN, a town of Germany, in the republic of Thuringia, 37 m. by rail N. of Erfurt. Pop. (1925) 10,122. It possesses a castle and manufactures of woollens and bricks. Potassium salts are also mined here. The town was formerly the capital of the principality of Schwarzburg-Sondershausen.

SONDRIO, a town of Lombardy, Italy, capital of the province of Sondrio, in the Valtellina, 1,140 ft. above sea-level, on the river Adda, 26 m. E. of Lake Como and 82 m. by rail N.E. of Milan. Pop. (1921) 9,807. Sondrio has silk-works. Above the town to the north rise the snowclad peaks of the Bernina group. The railway goes on to Tirano, 16 m. farther east, and thence over the Bernina pass into Switzerland, while the Stelvio road crosses to Spondigna in the upper valley of the Adige (now called the Val Venosta).

SONE or Son, river of central India identified with the Erannoboas of the Greek geographers. With the exception of the Jumna it is the chief tributary of the Ganges on its right bank. It rises in the Amarkantak highlands about 3,500 ft. above sea-level, and flows north-west until it strikes the Kaimur range, which constitutes the southern wall of the Gangetic plain. Here it turns east and continues until it falls into the Ganges about 10 m. above Patna, after a total course of 465 m. The Sone canals, fed by the river, form a great system of irrigation in the province of Bíhar.

SONG. All song, indeed all music, is based upon folk-song. Folk-song in Europe reached what may be considered its highest point of development in the 15th and 16th centuries. There is, to be sure, an antiquarian interest attaching to the melodic side of the songs of the troubadours, trouvères and minnesingers, who flourished in the 12th and 13th centuries; but it may reasonably be said that till the 17th century, the only form of song of musical importance was the folk-song, and that the songs of the minstrels were most successful when they took their inspiration from it. They were in fact poets, who, whether musically gifted or not, were forced by tradition to provide their poems with a musical, *i.e.*, melodic, counterpart. What the nature of their instrumental accompaniments was, is unknown.

From the musical standpoint, folk-song represents vocal melody evolved with no thought of harmony or an accompanying instrument. Its poems are in stanzas, the same melody serving for each. The melodies are formed on certain natural scales or modes, which were the heritage of the Indo-European races, and were in common use in all music, till about the year 1600, when harmony established itself as the basis of music, bringing the era of vocal counterpoint to an end, and substituting for the old modes our present major and minor scales; lastly, the folk-song is instinctive music, arising from the necessity inherent in the human race to use the voices which nature has bestowed upon it, in order to give expression to feelings, for which speech alone is felt to be inadequate. From whatever rude beginnings it evolved, the final fruit of this instinct is the melody we find in folk-song, a natural product, an unconscious art, which stands in contrast with the creations of conscious art, *i.e.*, songs by trained musicians, who invent their own melodies and provide them with instrumental accompaniments.

It is with these latter alone that this article is concerned, folk-song being dealt with in a separate article.

At the close of the 16th century the lute was the popular musical instrument of the educated classes. It was at this time that the first really important body of song was produced, especially in England. At first it may be described as a small satellite detached from the large planet of the madrigal, which had for about a century held the field as the favourite diversion of musical amateurs. There is little doubt that the idea of solo song arose when in madrigal singing the parts of missing voices were taken by instruments; it is plain that if all the voices but one were missing, the effect of a solo song with instrumental accompaniment was realized; a still nearer approach to artistic solo song was reached when the singer sang his own part of a madrigal, playing the other parts himself. In Dowland's *First Book of Songs or Airs* in four parts (published in 1597), the principal vocal melody has an alternative accompaniment for three additional voices or the lute. Most of the English madrigals were published "for voices or viols."

In Italy Caccini published in 1601 his famous collection of songs for the lute (*Nuove Musiche*). He claimed in his preface to be the first to invent songs "for a single voice to the accompaniment of a single instrument." It is true that his friends in Rome (his native city), at whose houses these new compositions were performed, assured him that they had never heard the like before, and that his style exhibited possibilities for the expression of feeling that were excluded when the voice sang merely one part in a contrapuntal work. But, about 30 years before Caccini, lutenists in France had anticipated his innovation, and composed solo songs with lute accompaniments in which is evidenced the struggle, not always successful, to break away from polyphonic traditions. Le Roy's *Airs de Cour,* published in 1571, may be cited in proof of this statement (*see* a book of *French Ayres,* Peter Warlock, 1928, in which the lute accompaniment has been transcribed for the piano). Of these airs "Je suis amour" is somewhat in the declamatory recitative style of Caccini's *Nuove Musiche* (see *Sämmelbande Int. Musik Gesellschaft,* article "Airs de Cours d'Adrien Le Roy," by Janet Dodge). Generally speaking, it may be said of early French songs that they were longer in shaking off the influence of the past than the songs of the Italians, many tricks of expressions, belonging to polyphonic times, surviving both in voice parts and accompaniments.

In England, about the end of the 16th century several volumes of songs to be sung with lute accompaniment made their appearance. It is worth observing that several were of earlier date than the "new music" of Caccini; they were an entirely English product. Some were songs or airs of four parts with tablature for the lute, so made that all the parts together or either of them separately could be sung to the lute, or orpharion; some were published only for a solo voice and lute. Dowland, who composed 87 songs, was undoubtedly the greatest of the large band of English lutenists. Even when, as in the first book of airs (1597), his songs could be sung by four voices, they distinguished themselves from the madrigal by the special melodic interest given to the top part. He was thus really the creator of the modern art-song. Though Byrd had (about 1583) composed "My Little Sweet Darling" and a few other songs with string accompaniment he did not, like Dowland, make the new type of song a special study. Dowland's fame, apart from the peculiar charm of his melodies, their expressive character, and their fitness to the words—a point which is characteristic of the work of the early lutenists—rests upon the important part he assigns to the lute. In many songs it contributes more to the expression than the vocal melody itself. Being himself not only a distinguished lutenist but a distinguished singer, he understood what it is that makes a song a joy to sing—as later Schubert, also a singer, understood. It became in fact an art-form. "Dowland was the first to specialize in this form and to develop it, and the art songs of Schubert, Schumann and Brahms with pianoforte accompaniment are lineal descendants of Dowland's songs with lute accompaniment" (Dr. Fellowes). The following songs, "Can she excuse my Wrongs," "Sorrow Stay," "Flow My Tears," "Weep You no More Sad Fountains," "In Silent Night," "Fine Knacks for Ladies," and "Once Again," may be cited as supporting this statement.

Campion, Rosseter and Jones are, after Dowland, the most individual composers in the same field. Campion's "There is a Garden in Her Face," "Shall I come if I Swim?"; Rosseter's "If She forsake Me," "When Laura Smiles" and "Would you see My Mistress' Face"; Jones's "Go to bed Sweet Muse" and "Sweet Kate" are good examples of their work. Each of these composers wrote about 100 songs.

Italy.—Meanwhile Italian composers, in spite of the frottole, villote, villanelle, balletti and falalas (arrangements in vocal parts of popular melodies common in Italy and other countries in the last half of the 16th century) seem to have been unaffected in the new song movement by popular influences (we have practically no knowledge of the Italian folk-song in mediaeval times); they went straight from the polyphonic to the recitative style (invented by Peri and Caccini for their early experiments in opera in 1600) and advanced with extraordinary rapidity.

MELODY AND RECITATIVE

In opera and cantata melody was quickly added to relieve the monotony of recitative, which must have been acutely felt by the hearers of such works, and considerable advance in this direction was made by Cavalli and Cesti (see *Oxford History of Music,* vol. iii., for details of their methods). Monteverde, though a greater genius than either of them, did not succeed in forcing the daring qualities of his own conceptions on others. The famous lament of Ariadne was the expression of an individual genius casting all rules aside for the sake of poignant emotional effect, rather than the beginning of new style in song. Carissimi and Rossi in oratorio and cantata (a word which then merely described a piece that was sung, as sonata a piece that was played, consisting generally of alternate recitative and aria) brought the organization of melody to a high degree of elaboration, far beyond anything attempted by Cavalli or Cesti. In their hands the declamatory methods of Monteverde were made subordinate to larger purposes of design. A broad and general characterization of emotional situations was more natural to them and to their successors than a treatment in which points were emphasized in detail. It was, moreover, inevitable in these early developments of musical style, in which melody played the leading part, that such sacrifices as

were necessary in balancing the rival claims of expression and form should be in favour of the latter, rather than the former. But the formal perfection of melody was not the only problem which 17th century Italian composers had to face. The whole question of instrumental accompaniment had to be worked out; the nature and capacities of instruments had to be explored; the reconciliation of the new art of harmony with the old art of counterpoint to be effected. It speaks volumes for the innate musical sense and technical skill of the early Italian composers that the initial stage of tentative effort passed so quickly, and that at the close of the 17th century we are conscious of breathing an atmosphere not of experimental work, but of mature art.

Alessandro Scarlatti (1659–1725) sums up the period for Italy. That much of his work is dry and uninspired is not surprising when the quantity of it is realized (he composed over 100 operas and 500 vocal cantatas) and also the unfavourable conditions under which operatic composers had to work; but the best of it is singularly noble in conception and perfect in design. The same is true of the best work of Legrenzi, Durante, Leonardo Leo and Caldara, work which was of incalculable importance for the development of musical, and particularly of vocal art, and which will always, for minds attuned to its atmosphere of severity and self-restraint, possess an abiding charm; but comparatively few specimens have retained the affections of the world at large. Carissimi's "Vittoria," Scarlatti's "O cessate" and "Le Violette" are the most notable exceptions ("Pietà Signore" is not included, as no one now attributes it to Stradella).

The almost universal preference of the Italians in the 17th and 18th centuries for the *da capo* aria involved some sacrifice on the dramatic and emotional side; this becomes clear at once if we think of an opera in which nearly all the songs end by repeating not only the melody of the opening part, but the words attached to it. It is this double repetition which from the point of view of dramatic propriety is the most disturbing. But composers were too much occupied in exploring the formal possibilities of melody to establish a really intimate connection between music and text, a detailed interpretation of which lay outside their scheme of song. Much repetition of words was not felt as an absurdity so long as the music was broadly in accordance with the atmosphere or situation required.

When detailed and impassioned treatment was needed, composers turned to what is known as *recitativo arioso,* of which remarkably fine specimens appear in Scarlatti's operas and cantatas. But the masterpieces in this style are in the works of Handel and Bach.

Before Scarlatti's death in 1725 symptoms of decline had appeared. He was himself often compelled to sacrifice his finer instincts to the popular demand for vocal display. A race of singers, of whom the majority were virtuosi rather than artists, dominated the taste of the public, and forced composers to furnish opportunities in each rôle for a full display of their powers. It was not long before more obvious types of melody, expressing more obvious feelings, became the fashion. The varied forms of accompaniment, in which a contrapuntal bass had been a conspicuous feature, were wasted upon a public which came to hear vocalists, not music; and stereotyped figures, of the kind which second-rate art after the first half of the 18th century had made only too familiar, took the place of sound workmanship, so that the Italian school, which had stood as a model for the world, became identified with all that was trivial, insipid, and conventional. Not that the Italian tendency in the direction of tunefulness was in itself either unhealthy or unworthy. It was indeed a necessary reaction, when the severe earlier style began to pass into cold and calculating formalism. But the spirit of shallowness and frivolity which accompanied the reaction helped to transfer the musical supremacy hitherto enjoyed by Italy to Germany, the only country which, while accepting what was necessary to it of Italian influences, remained true to its own ideals.

Germany.—The musical genius of Germany, which has created for the world the highest forms as yet known of symphony, oratorio and opera, has also created the *Lied*—the term by which is most easily conveyed the modern conceptions of ideal song. Germany is, moreover, the only country in which the art of song in orderly and progressive development can be traced from the simple mediaeval Volkslied to the elaborate productions of Schubert, Schumann and Brahms. If Germany is united to the rest of Europe in her debt to Italy, still her final conception of song belongs to herself alone. And this conception has more profoundly influenced the rest of Europe than any Italian conception ever influenced Germany. The student, therefore, is more profitably employed in studying the phases of song development in Germany than in any other country.

It is not necessary to dwell, except in very general terms, upon German song of the 17th century. It can point to nothing corresponding with the *Airs de cour* of France, or the far more important songs of the English lutenists. The kind of literature necessary for such development was wanting. German art was too deeply affected by the spirit which produced the Reformation to develop freely in secular directions. Even in the domain of the Volkslied the sacred songs were scarcely less numerous than the secular, quantities of secular airs being provided with sacred words in accordance with the spirit of the times. In the 17th century, the work of the Italian monodists was bound eventually to stimulate German composers to make songs, but their interest at first lay more in opera and choral-instrumental works, in which solo songs appear, than in song as an independent branch of art. A good general view of such isolated songs as appeared can be obtained from Reimann's collections *Das Deutsche Geistliche Lied* and *Das Deutsche Lied* (Simrock).

In spite of some stiffness and awkwardness, many of these exhibit a touching earnestness and sincerity which mark them as distinct from any work done elsewhere at the same time. On the other hand, they lack the certainty of touch, as well as the melodic and declamatory power, which make Purcell in England stand out pre-eminently as the greatest song composer of the 17th century. The treatment of the aria by Bach and Handel lies outside the scope of this article. Nor shall we pause to consider the songs of lesser composers, eminent in their day, such as Telemann (1691–1767), Graun (1701–1759) and Agricola (1720–1774), whose vocal work was confined to oratorio, opera and cantata.

At the outset it is necessary to distinguish between that more distinctly popular type of song, known as the *Volksthümliches* Lied, in which the same melody served for all the stanzas of a poem (as in the Volkslied itself, on which the *Volksthümliches* Lied was modelled), and the *durchcomponiertes* Lied, or song "composed through," in which the music forms a running commentary on a poem, without respect to its form, or, if stanza form is preserved, varying the music in some stanzas or in all in accordance with their poetical significance. Generally speaking, the former aims at a wider audience than the latter, the appreciation of which involves some degree of culture and intelligence, inasmuch as it aims at interpreting more complex and difficult kinds of poetry. In the 18th century the simple *Volksthümliches* Lied in strophic form was most in favour, and those who care to trace its history in the hands of popular composers like J. A. Hiller, J. A. P. Schulz, Reichardt, and Zelter, can easily do so by consulting Härtel's *Liederlexicon* (Leipzig, 1867), one of a number of similar publications. Side by side with the outpouring of somewhat obvious and sentimental melodiousness which such volumes reveal, it must be remembered that the attention of greater men to instrumental composition, the growing power to compose for keyed instruments (which began to replace the lute in the middle of the 17th century) and the mechanical improvements through which spinet, clavichord and harpsichord were advancing towards the modern pianoforte, were preparing the way for the modern Lied, in which the pianoforte accompaniment was to play an increasingly important part. C. P. E. Bach (d. 1788) alone of his contemporaries gave serious attention to lyrical song, selecting the best poetry he could get hold of, and aspiring to something beyond merely tuneful melody. The real outburst of song had to wait for the inspiration, which came with the poetry of Goethe and Schiller.

Haydn and Mozart.—It is unfortunate that Haydn and Mozart, endowed with all the gifts that make for beautiful song

except that of literary discrimination, should have left so little of real value. There is, indeed, much to admire in some of Haydn's canzonets, of which "My mother bids me bind my hair" fully deserves its popularity, while Mozart's "Trennung," "Unglückliche Liebe," and "Komm' lieber Mai," are small treasures which we could not afford to lose. But in only two songs by Mozart, "Abendempfindung" and "Das Veilchen," is the goal to which the art was to advance clearly discerned and in the latter case perfectly attained. Both are *durchcomponiert,* in both the general spirit, as well as each isolated point of beauty in the verses is seized and portrayed with unerring insight. "Abendempfindung" is seriously marred by carelessness in accentuation (still worse examples may be seen in "An Chloe") and by annoying repetition of words, due to the development of the melody into a formal and effective climax, on instrumental, not vocal, lines.

In "Das Veilchen," however, where Mozart touched a poem that was worthy of his genius, he produced a masterpiece—rightly regarded as the first perfect specimen of the *durchcomponiertes* Lied. Every incident in the flower's story is minutely followed, with a detailed pictorial and dramatic treatment (involving several changes of key, contrasts between major and minor, variations of rhythm and melody, declamatory or recitative passages), which was quite new to the art.

Beethoven.—With Beethoven, song was suddenly exalted to a place among the highest branches of composition. Taken in hand with the utmost seriousness by the greatest musician of the age and associated by him, for the most part, with lyrical poetry of a high order, it could at last raise its head and, freed from the conventional puerilities of the salon, look a larger world confidently in the face.

It cannot, however, be admitted that Beethoven was an ideal song composer. His genius moved more easily in the field of abstract music. The forms of poetry were to him rather a hindrance than a help. His tendency is to press into his melodies more meaning than the words will bear. The very qualities, in fact, which make his instrumental melodies so inspiring, tell against his songs. Though his stronger critical instinct kept him, as a rule, from the false accentuation which marred some of the work of Haydn and Mozart, yet, like them, he could not free himself from the instrumentalist's point of view, at any rate in the larger song-forms. The concluding melody of "Busslied" would be equally effective played as a violin solo; the same is true of the final movements of "Adelaïde" and of the otherwise noble cycle "An die ferne Geliebte"—movements in which the words have to adapt themselves as well as they can to the exigencies of thematic development and to submit to serious displacements and tiresome repetitions.

In songs of a solemn or deeply emotional nature, Beethoven is at his best, as in that cycle, to sacred words of Gellert, of which "Die Ehre Gottes aus der Natur" stands as a lasting monument of simple but expressive grandeur, in "Trocknet nicht," "In questa tomba," "Partenza," in the first of four settings to Goethe's "Nur wer die Sehnsucht kennt," and more than all, in the cycle mentioned above, "An die ferne Geliebte." We have left behind the pretty artificialities so dear to the 18th century, that play around fictitious shepherds and shepherdesses, and enter the field of deeper human feeling, with the surrounding influences upon it of nature and romance.

The new spirit of the age, represented in German poetry by the lyrics of Bürger, Voss, Claudius and Hölty, members of the famous Göttinger Hainbund, and more notably by those of Goethe and Schiller, communicates itself in Beethoven to song. It needs no large study of his songs to perceive that the accompaniment has assumed, especially in the "Liederkreis," an importance immeasurably greater than in the songs of any previous composer. It begins to take a real, not a perfunctory, part in interpretation, providing both a background and a commentary to the poet's verses.

Schubert.—The pioneer work of Schulz, Reichardt and Zelter in the setting of Goethe's lyrics deserves—for they did not confine their activities to popular songs—mention as indicating the direction in which composers were moving; a word is also due to Zumsteeg, who, in spite of the sometimes childish simplicity of his work, yet, in the use which he made of modulation as a means of lyrical expression, had some influence upon the greatest song writer of all ages, Franz Schubert.

Schubert's "Erlkönig" was written a few months before Beethoven's "Liederkreis"; "Gretchen am Spinnrade," about a year before the "Erlkönig." He was 18 when he composed the latter, in 1815. Lyrical song, divorced from all hindering elements and associations, whether of salon or theatre, was here at the threshold of his short career in almost full maturity and plenitude of power. It is sufficiently remarkable that a lad with so little education should have composed such music; it is more astonishing still that he should have penetrated with unerring insight into the innermost secrets of the best poetry. Two of the necessary qualifications for a great song composer were thus at last united. Schubert possessed the third—a knowledge of the human voice, partly intuitive, partly the result of his experience as a chorister boy. The beauty of his melodies is scarcely more striking than the gratefulness of their purely vocal qualities. The technique of singing had, indeed, been understood for nearly two centuries; but Schubert was the first to divine fully its emotional range, and to dissociate it in lyrical work from the traditions of the schools. From the beginning to the end of his career he never penned a note or a phrase merely because it was vocally effective. What he wrote for the voice to sing was there because for him the poetry could not have it otherwise. This was inherent in his method of working, in which he relied implicitly upon his musical inspiration for a response, usually instantaneous, to the inordinate receptivity of his mind to the impressions of poetry. To read through a poem was for him not only to seize its innermost significance and the salient points of its language and its form, but also to visualize the scheme by which both the whole and the parts could be translated and glorified through the medium of music. As the singer Vogl, the first of his profession to appreciate him, remarked, "He composed in a state of clairvoyance." Hence the impossibility of summarizing in a short space the innovations he introduced: for new poems immediately suggested new types of song. His settings to Goethe's lyrics, that is, the best of them, differ as essentially from his settings to those of W. Müller in the cycles "Die schöne Müllerin" and "Die Winterreise," as these, again, from the settings of the six poems of Heine.

Hardly a single development in subsequent phases of the art (except those which eliminate the melodious element) is not foreshadowed in one or other of his songs (about 656 in number). Brahms, the greatest of his successors, said that there was something to be learned from every one of Schubert's songs. He was as perfectly at home in the *durchcomponiertes* Lied as in the simple strophic type, or the purely declamatory. "Der Wegweiser," "Haidenröslein," "Der Doppelgänger" are familiar but supreme examples of each. Certain features may be selected for emphasis: first, his use of modulation as a means of emotional expression. "Du liebst mich nicht" traverses, in two pages, more keys than would serve most composers for a whole symphony—while the discords on the words "Die Sonne vermissen" and "Was blühen die Narcissen" give a piercingly thrilling effect which is quite modern. The modulations in "Wehmuth" illustrate the subtle atmospheric effects which he loved to produce by sudden contrasts between major and minor harmonies. More familiar instances occur in "Gute Nacht," "Die Rose," and "Rosamunde." Secondly, his inexhaustible fertility in devising forms of accompaniment which serve to illustrate the pictorial or emotional background of a poem; we have the galloping horses and the horn in "Die Post," the spinning wheel in "Gretchen," murmuring brooks in many songs from "Die schöne Müllerin" and "Liebesbotschaft," the indications of an emotional mood in "Die Stadt" or "Litanei." Occasionally, it is true, the persistence of a particular figure or rhythm induces monotony, as in "Ave Maria" or "Normans Gesang," but generally Schubert had plenty of means at his command to prevent it, such as the presence of an appropriate subsidiary figure making its appearance at intervals, as in "Halt," "Der Einsame," or some enchanting ritornello, by which a phrase of the vocal melody is echoed in the accompaniment, as in "Liebesbot-

schaft," "An Sylvia," "Ständchen" and "Fischerweise," or variations in the accompaniment to the different stanzas, as in "Der Frühling." Thirdly, the sudden entrance of declamatory passages, as in "Der Neugierige," "Am Feierabend," in "Gretchen" at the famous "Ach, sein Kuss." Fourthly, the realistic touches, by which suggestions in a poem are incorporated into the accompaniment, such as the cock crowing in "Frühlingstraum," the convent bell in "Die junge Nonne," the nightingale's song in "Ganymed," or the falling tears in "Ihr Bild." Finally should be noted the rarity of slips in the matter of the just accentuation of syllables; and this is specially remarkable in a song writer who relies so much upon pure melody as Schubert; for to find and preserve a melodic outline which is felt as a true expression of a poem and yet does no violence to its text is far more difficult than to compose in the declamatory style. But nothing is difficult to Schubert. He is as successful in "Liebesbotschaft" as in "Prometheus."

For further details the reader is referred to the brilliant essay on song, with which Sir Henry Hadow concludes vol. v. of the *Oxford History of Music.* It must suffice here to point out in a general way that in wideness of scope and aim, in intensity of expression, Schubert produced the same transformation in the lyrical field that Beethoven had produced in the larger forms of sonata, string quartette and symphony. Beethoven's work was necessary before Schubert could arise, but Schubert's conceptions and methods were the fruit of his own genius.

Loewe and Weber.—Of his contemporaries, Loewe deserves mention for his singular success in overcoming the difficulties involved in setting long ballads to music. To preserve homogeneity in a form in which simple narration presents perpetually shifting changes of action, of picture, of mood, is a problem which Schubert himself only once triumphantly solved. Weber contributed nothing of permanent value to song, outside his operas, beyond a few strophic songs of a popular nature. He disqualified himself for higher work by that singular preference for vapid and trivial verse, which so often led Haydn and Mozart astray.

Mendelssohn and Schumann.—Mendelssohn's literary tastes took him often to the best poems but he made but little attempt to penetrate beyond their superficial and obvious import. His own lovable personality is far more clearly revealed in his songs than the spirit of his poets. Differences of literary style affected the style of his music less than that of any other distinguished composer. He attained his highest level in "Auf Flügeln des Gesanges," in the first of the two songs to "Zuleika," and "Nachtlied."

It is noteworthy that there is no trace of Schubert's influence. Had he never lived, Mendelssohn's songs would have been just the same. Hence, in spite of graceful and flowing melodies, simple in form and instinct with that polished taste and charm of manner which endeared both himself and his works to his own generation, his songs have exercised no permanent influence upon the art. Their immediate influence, it is true, was enormous: it is felt occasionally in Schumann, only too often in Robert Franz, and in the work of many composers of more or less distinction in many countries besides his own, such as Gade, Lindblad, Sterndale Bennett and others who need not be specified.

Of far greater importance is the work of Robert Schumann, whose polyphonic methods of technique and peculiarly epigrammatic style enabled him to treat complex phases of thought and feeling, which had hardly become prominent in Schubert's time, with extraordinary success. Both by temperament and by choice he identified himself with the so-called Romantic movement, a movement in which both poetry and music have tended more and more to become a personal revelation rather than "a criticism of life." With Schubert, who was the very incarnation of romance, the note of universality, that abiding mark of the classical composers, is stronger than the impress of his own personality.

With Schumann the reverse is the case. If the Romantic movement gave a new impetus of vast importance both to music and literature, it had its weaker side in extremes of sensibility which were not always equivalent to strength of feeling. Mendelssohn's songs admittedly err on the side of sentimentality—Schumann, with Liszt, Jensen, and Franz, frequently betrays the same weakness. His best work appears in the settings of Heine's lyrics (especially the *"Dichterliebe"*), in the "Eichendorff," "Liederkreis," in Chamisso's *"Frauenliebe und Leben,"* and a fair number of other songs, such as "Widmung," "Der Nussbaum," "Aufträge," and on the dramatic side in "Der Soldat," "Die Karten-Legerin" and "Die beiden Grenadiere," all strong in feeling and full of poetic and imaginary qualities of a high order. He realized that the new poetry called for new methods of treatment. These Schumann, instinctively an experimenter, provided, first, by a closer attention to the minutiae of declamation than had hitherto been attempted, and herein syncopation and suspension provide possibilities unsuspected even by Schubert (in whose work hardly a case of syncopation will be found in the voice part); secondly, by increasing the rôle of the pianoforte accompaniment—and in this he was helped on the one hand by novel methods of technique, of which himself and Chopin were the chief originators, and on the other by his loving study of Bach, which imparted a polyphonic element which was new to modern song. In nearly all Schubert's songs, and in all of Mendelssohn's, the melody allotted to the voice is an essential factor. In Schumann the rôle of interpreter often passes to the accompaniment, while the voice declaims the words, as in "Es ist ein Flöten und Geigen," or "Rösslein," but the notes in which it declaims them are musically important. Consistently with this attitude, he gave increased prominence to the opening and closing instrumental symphonies; these became in his hands no merely formal introductions or conclusions, but an integral part of the whole conception and fabric of the Lied. This may be illustrated by many numbers of the "Dichterliebe," but most remarkable is its final page, in which the pianoforte, after the voice has stopped, sums up the whole meaning of the cycle.

A third point is his fondness for short, interrupted phrases (often repeated at different levels) in place of the developed Schubertian melodies; a practice which has been extended by later composers, but often, as in the case of Franz, without Schumann's tact. On many grounds, then, Schumann may be regarded as having widely extended the conception of the Lied; his example has indeed encouraged later composers to regard no lyric poetry as too subtle for musical treatment.

A bold experimenter in song was Franz Liszt, whose wayward genius, with its irrepressible bent towards the theatrical and melodramatic, was not at home within the limits of a short lyric. It is true that there is sincerity of feeling, if not of the deepest kind, in "Es muss ein Wunderbares sein" and "Ueber allen Gipfeln," but concentrated emotion, which involves for its expression highly organized form, was alien to Liszt's genius, which is more truly represented in songs like "Die Lorelei," "Kennst du das Land" or "Am Rhein," in which are presented a series of pictures loosely connected, giving the impression of clever extemporizations. It is not sufficiently recognized that such work is far easier to produce than successful strophic song, even of the simplest kind.

The popularity, therefore, of "Die Lorelei," is not so much a tribute to Liszt's genius, as an example of the extent to which gifted singers and undiscerning critics can mislead the public. Mere scene painting, however vivid, however atmospheric—and these qualities may be conceded to Liszt, and to others who have followed his example—takes its place upon the lower planes of art.

The admiration expressed by Liszt and Wagner for the songs of Robert Franz, and the cordial welcome extended by Schumann to those which first made their appearance, have led to an undue estimate of their importance in many quarters. They are characterized by great delicacy both of feeling and of workmanship, but the ingenuity of his counterpoint, which he owed to his intimate knowledge of Bach and Handel, cannot conceal the frequent poverty of inspiration in his melodic phrases, nor the absence of genuine constructive power. To build a song upon one or two phrases repeated at different levels and coloured by changing harmonies to suit the requirements of the poetic text (as in "Für Musik" and "Du bist Elend") is a dangerous substitute for the power to formulate large and expressive melodies. But it is the method which Franz frequently pursued. His songs are mostly short and in the strophic form, some alteration being reserved to

give point to the last verse. His tricks of style and procedure so quickly become familiar as to exhaust the patience even of the most sympathetic student. But the sincerity of his aims, the idealistic and supersensitive purity of his mind (which banished as far as possible even the dramatic element from his lyrics), its receptiveness to the chaste, tender and refined elements in human character render his songs an important contribution to our knowledge of the intimate side of German feeling, and provide some compensation for the lack of the larger qualities of style and imagination. His best qualities are represented in the beautiful setting to Lenau's "Stille Sicherheit."

Peter Cornelius.—A higher value than is usually conceded, attaches to the songs of Peter Cornelius, a friend of Liszt and Wagner, but a follower of neither. Before he came under their influence, he underwent a severe course of contrapuntal training, so that his work, though essentially modern in spirit, has that stability of structure which makes for permanence. He was, moreover, an accomplished linguist, a brilliant essayist and a poet. That intimate fusion between poetry and music, which since Schubert has been the ideal of German song, is realized in an exceptional manner, when, with Cornelius as with Wagner, librettist and musician are one person.

Finer declamation is rarely found than in his subtly imaginative "Auftrag," whilst for beauty of feeling, apart from technical excellencies of a high order, the "Weihnachtslieder," the "Brautlieder" and much of the sacred cycle *"Vater Unser"* are hardly surpassed even by Schumann at his best, and point to Cornelius as one of the most beautiful and original spirits of the 19th century.

In the song work of the 19th century, though Schubert is the rock upon which it has been built, Schumann represents the most directly inspiring influence, even when, as in the case of Adolph Jensen (whose spontaneously melodious and graceful songs deserve to be better known), there are importations from such widely divergent sources as the works of Mendelssohn and Wagner.

The application of the principles of Wagnerian music-drama to lyrical work was, sooner or later, bound to come and, for a time, to bring confusion. Song was rescued from it by the work of two men of genius who, though they approached the task from very different standpoints, may be considered to have placed the crown of final achievement upon the aspirations of 19th century song—Johannes Brahms and Hugo Wolf. The songs of Wolf are treated elsewhere. (*See* Wolf.) Here it is only necessary to say that he exhibits an entirely unconventional and original style. He is as untroubled by tradition as Schubert, whom he resembles, not often (as in "Fussreise" and "Der Gärtner") in pure melodiousness, but in the intensity of his power to penetrate to the heart of poetry. To him may also be fitly applied the epithet "clairvoyant." He was the first to publish songs "for voice and pianoforte," not "songs with pianoforte accompaniment," thus asserting the equality of singer and accompanist in interpretation.

NINETEENTH-CENTURY SONG ACHIEVEMENT

Brahms.—The unerring sagacity of Brahms discerned that the possibilities of song on the lines set by Schubert were far from being exhausted: his practical mind preferred to develop those possibilities rather than to seek after strange and novel methods, conforming thus, in song, to his practice in other branches of composition. A broad melodic outline was for him essential; also a strong contrapuntal bass. In form, the majority of his songs are strophic and follow the orthodox ABA or AABA pattern (the letters standing for stanzas), the central portion, B, being so organized as to offer, with the least possible introduction of new material, a heightened contrast with the opening portion through changes of rhythm and tonality, and at the same time to justify itself by producing the mood in which the return to the opening portion is felt as a logical necessity. Chromatic effects in Brahms's scheme of melody are rarely introduced till the middle section, the opening being almost invariably diatonic. It must, however, be admitted that Brahms's formal perfection involves some awkward handling of words, as in the second stanza of "Feldeinsamkeit"; sometimes, as in Nos. 3 and 4 of the *Magelone Lieder,* they are frankly sacrificed to that formal development of material which has already been criticized in the cases of Mozart and Beethoven.

No part of his songs deserves closer study than the few bars of instrumental prelude and conclusion; in them is enshrined the very essence of his conception of a poem. It may almost be said that, since Schumann set the example, the first and the last word have passed from the voice to the instrument, from the singer to the accompanist, who is called upon to understand poetry as well as music. Mastery in close organization of form was allied in Brahms not only with the warmth and tenderness of romance, but with the imagination and insight of an earnest thinker. Concentration of style and of thought are nowhere else in the history of the Lied combined on a plane so high as that which is reached, with all perfection of melodic and harmonic beauty, in "Schwermuth," "Der Tod, das ist die kühle Nacht," "Mit vierzig Jahren," "Am Kirchhof," "O wüsst' ich doch den Weg zurück," and the "Vier ernste Gesänge," which closed the list of his 197 songs. The alliance to song of so dangerous a companion as philosophy, or at any rate of thoughts which are philosophical rather than lyrical, proved no obstacle to Brahms's equal success in the realm of romance. This side of his genius may be illustrated by numerous songs from the *Magelone* cycle (notably "Wie froh und frisch" and "Ruhe, süss Liebchen") and by many others such as "Liebestreu," "Die Mainacht," "Feldeinsamkeit," "Wie rafft' ich mich auf in der Nacht," "Minnelied," "Immer leise wird mein Schlummer," "Lerchengesang," "Wie Melodien zieht es," "Geheimniss" and "Dein blaues Auge."

It has already been said that Brahms was a student of Schubert. If he had not Schubert's spontaneity of melody, he restored it to its Schubertian place of supreme importance. In spite of all the tendencies of his age, he never shirked that supreme test of a composer, the power to originate and organize melody, but it is melody which with its long phrases, its wide skips and something uncompromising in its nature may repel those hearers who are unable to attain to his level of thought and feeling. All mere prettiness and elegance are as alien to his nature as sentimental weakness on the one hand, or realistic scene painting on the other, so that, for the world at large, his popularity has been jeopardized by an attitude which is felt to be unnecessarily lofty and austere. It has found it difficult to reconcile itself to the treatment of modern lyrical poetry in a style whose elaborate contrapuntal texture differs as much from the delicate polyphony of Schumann, as that in its turn differed from the broad harmonic style of Schubert. But that Brahms is not difficult without reason, or elaborate when he might have been simple, may perhaps be assumed from the preference he felt for his slighter songs in the *Volksthümlich* form and style (*e.g.*, "Abschied," "Sonntag," "Vergebliches Ständchen" and "Wiegenlied").

He was strongly influenced by the Volkslieder of his country, the words of which he loved to repeat to himself, as they suggested ideas even for his instrumental compositions. His arrangements of Volkslieder, though not uniformly successful, mark an epoch in that field of work. Curiously enough, his love of folk-songs did not involve the sense which distinguishes between the genuine and the sham. Of the 49 Volkslieder published without opus number in 1894 by far the greater number were imitations which are really quite easy to recognize as such. (See *Brahms's Lieder* by Max Friedländer.)

The value of his arrangements may be tested by comparing them with the small volume containing arrangements by R. Franz, which are ingeniously done but without inspiration, with those of Tappert, which are models of what such things ought not to be, and with the dull, uninviting work of A. Saran. Many of Reimann's arrangements, however, deserve recognition as both sympathetic and scholarly. One fact emerges clearly from the study of folk-song arrangements, in Germany and elsewhere, that complete success depends upon qualities which are as rare as, and seldom dissociated from, the power of original composition. Only a great composer can be a great arranger. When Brahms's songs are considered as a whole, it is difficult to conceive of more

complete work on lines that are essentially classical. The soundest traditions find in them their justification and their consummation. He has enshrined the best thought and the noblest feeling of his age in forms where elaboration and complexity of detail serve essential purposes of interpretation and are never used as a brilliant artifice to conceal foundations which are insecure.

The above summary of German song, though necessarily incomplete and confined to the most conspicuous names, may yet provide some points of view from which the songs of other countries may be regarded, especially those in which German conceptions and German methods of technique have been dominant factors. Actual settings of German lyrics figure largely in the works of many non-German composers and can hardly be judged except by German standards; Rubinstein, Tschaikovsky, Grieg, are cases in point.

It remains now to conclude the survey of German song by touching on the work of a few prominent modern composers, who may be regarded as having enlarged the scope of the Lied without entirely breaking with its past.

Hans Pfitzner (b. 1869), a composer who may be counted among the old romantics, has enriched traditional forms rather than created new ones. His songs are felt to be individual experiences, they are "original but not at the cost of music" (Oscar Bie), poetical and full of beauty. The charm of "Herbstlied," "Sie haben heut'Abend Gesellschaft," "So fällt ein Stern herunter," does not fade. Others worth quoting are "Das verlass'ne Mägdlein" and "Denk' es, O Seele," which may be compared with Hugo Wolf's settings of the same words, and "Du milchjunger Knabe," of which Brahms's setting is the best known.

Max Reger (b. 1873—d. 1916) composed 225 songs; they are worth exploring on account of the originality of his harmonies, and his extraordinary contrapuntal skill, which he used deliberately with more thought for expression than for beauty. Overweighted with much learning, they make no great appeal to the singer's instincts. With the exception of some of the Wiegenlieder, especially "Wiegenlied-Maria," some of the Schlichte Weisen (especially "Waldeinsamkeit") and a few of his later songs, such as "Volkslied," "Sterbendes Kind" and "Unvergessen," the bulk of his work in song is not likely to be remembered.

Richard Strauss and Gustav Mahler.—The songs of Richard Strauss (b. 1864) represent a new departure, new, that is to say, to the 19th century, to which the bulk of them belongs. He is after Hugo Wolf, the most interesting of the modern composers who have applied the principles of Wagner to song. Discarding in many cases accepted forms, he has found freer play for his exceptional gifts in the matter of pictorial illustration and emotional colour. It is not surprising, therefore, that he has originated no great melodies, or indeed, composed many purely melodic songs, such as "Morgen," and "Du meines Herzens Krönelein," the melodies of which, if not highly organized, are graceful and appropriate. More often the phrase with which a song opens does not develop into a melody; we discover at once that the accompaniment with its rhythmical figure and changing harmonies is really in charge; and that the vocal phraseology, as the song proceeds, adapts itself to it. Though the plan is derived from Wagner, Strauss's music is both in style and feeling his own. "Ruhe, meine Seele," "Spätbot," "Traum durch die Dämmerung," one of his most beautiful creations, "Gefunden" and "Schlechtes Wetter" exhibit his best qualities; among them his power of depicting a given mood or atmosphere and sustaining it to the end. It must be admitted however that many of his songs, apart from their exceeding brilliance and effectiveness, both for voice and piano, *e.g.,* the popular "Ständchen" and "Heimliche Aufforderung," have no permanent value.

It is noteworthy that Strauss's name is not associated, as in the case of most of the German song composers, with any particular poet; he has composed no cycle; with all his varieties of style and resource, he exhibits but little power of characterization. His songs come to him too easily. There is nowhere the burning intensity of Schubert or Wolf.

In the songs of Gustav Mahler (1860–1911) we feel at once the presence of a tempestuous nature, tormented, restless, unsatisfied. He poured his heart into his songs and closest to his heart from boyhood were his native land (Moravia) and the old German folk-song. These were the inspiration of his music. What they meant to him is revealed in the series of vivid pictures, instinct with life, movement and colour, contained in the four "Lieder eines Fahrenden Gesellen" (originally for voice and orchestra) and in the three volumes of songs taken from *Des Knaben Wunderhorn* (a famous collection of old German songs and ballads). They are essentially dramatic songs, even realistic, full of melody of the folk-song type and provided with an accompaniment more orchestrally than pianistically conceived; the construction is apt to be loose and diffuse, with rough corners and purple passages; but they are original, alive, refreshing, worth knowing, in spite of blemishes, which are emphasized because they represent a danger to song; they bring it too close to the theatre. Lyrical moments have their place in opera, but the atmosphere of the Lied is disturbed by even a suggestion of the footlights. Rolland has pointed out that German music is losing "its intimate spirit" (a spirit which in a special sense belongs to the Lied) and he attributes this, with other disquieting signs, to the "detestable influence of the theatre to which nearly all these artists are attached as kapellmeisters or directors of opera." He is alluding specially to Strauss and Mahler. It should be added that the later songs composed by Mahler, after he had freed himself from operatic work, are quite different in style; they consist of five songs (not without interest) and the touching and deeply felt group of *Todtenkinderlieder,* the words of all being by Rückert.

There is a long list of composers, who like the above named are in touch with the old régime; many have written a number of attractive and well written songs, of which, in this country the best known are those of Felix Weingärtner (b. 1863) and Erich Wolff (*e.g.,* "Du bist so jung," "Alle Dinge haben Sprache," and "Faden"). Those of Joseph Marx (b. 1882) are at least equally striking, and perhaps more original. Philip Jarnach (b. 1892) has contributed some remarkable songs. Sensuous beauty has little attraction for him for its own sake, but he attains it sometimes, as it were, *malgré lui;* there is no superfluous ornament: when he strikes it is with *macabre* power. The concentration which he has given to his songs he expects from his hearers: he seems to have wrestled with the words he has set and drawn out their very heart. Among the most striking are "An eine Rose," "Jasmin," "Das mitleidige Mädel," "Lebenswege," "Freibeuter," "Japanesisches Regenlied," "Mailied" and many songs from the *Italienisches Liederbuch* (Paul Heyse). He may be said in his later work to belong to the school of Brahms—though the influence of Hugo Wolf is also felt.

PRESENT-DAY SONG

In recent years changes have taken place in the world of music quite as startling and revolutionary as those which, at the beginning of the 17th century, suddenly brought the days of vocal counterpoint and the modal system to an end and substituted harmony for melody as the basis of the "new music." Now, in its turn, the harmonic structure based on key relationship after three centuries of development, is being shaken to its very base and the world is talking once more of the "new music." Many composers in all European countries are exploring its possibilities and producing music, the value and meaning of which in its latest phases cannot be justly estimated at the present time.

Those who would study the "new music" in German song will find it in the later songs of Schönberg (b. 1874), in those of Webern (b. 1883), Krenek (b. 1900), and in Hindemith's (b. 1895) *Die junge Magd* (for contralto with flute, clarinet and string quartet) and especially *Das Marienleben* (a cycle for soprano with pianoforte accompaniment).

The Latin countries have been but little subject to German influences: France especially has always found from age to age, and notably in modern times, solutions of her artistic problems, which have proved of deep interest to those who live beyond her borders; they bear emphatically her own hall-mark.

France.—Allusion has already been made to the French as pioneers in establishing solo song to lute accompaniment, which

here, as in Italy, originated in adaptations of polyphonic compositions. But in France from the first, the main influence apart from opera, has come from popular sources, the native folk-song and the vaudeville, the ditties of country and of town. In both that union of grace, simplicity and charm, characteristic of the French nation, tended to produce an art of dainty unpretentious attractiveness. It preserved these characteristics in spite of the artificial atmosphere of the French Court, in which it mainly flourished, up to the time of the Revolution, in spite, too, of the somewhat different influences, which might have been expected to affect it, derived from opera, the mania for which did not, as in Italy kill the smaller branch of vocal music. Brunettes, musettes, minuets, vaudevilles, beorgerettes, pastourelles, as the songs were styled according to the nature of the poetry to which they were attached, may be found in Weckerlin's "Echos du temps passé" (3 vols. 1855).

The melodious style of Gounod (1818–1893), whose earlier songs are excellent, is felt as a real influence in the work of Massenet, Godard, Saint-Saëns, Delibes, Bizet, Lalo, Chaminade, Reynaldo Hahn and others, but it has yielded, during the last quarter of a century, to tendencies which corresponded closely with those of the Impressionist movement in French literature and painting. The new movement owed much to the work and inspiration of César Franck (whose actual contribution to song is small) but more to that of Fauré (b. 1845). The style of this master was new and individual. His harmonic conceptions, at first considered strange and revolutionary, were soon justified by the subtle effects of mood which they enabled him to express, as, for example, in "Les roses d'Ispahan," "Dans les ruines d'une abbaye," "Nell," "Le secret," "Lydie" and "Les berceaux."

If much of his work in song may be regarded as experimental, this cannot be said of Duparc (b. 1848) whose 15 songs rank among the choicest treasures of French art. They are characterized by an individual warmth, both of feeling and colour. The quietly moving, subtly blending harmonies and the smooth but expressive melodic line, most grateful to sing, are of a kind which it is impossible to associate with any poetry or any language but that of France. When he is dramatic his work is brilliant but without forced effects or violent transitions. César Franck was his master. (*See* the following songs:—"Extase," "La vague et la cloche," "Phydyle," "Chanson triste," and "Soupir.") To the same school belongs Chausson (b. 1855), whose songs are the expression of a refined and sensitive nature, remarkable for delicate beauty of detail and of form, somewhat after the manner of Duparc but on a smaller scale: *e.g.,* "Le temps de lilas," "Les papillons," "Nanny," "La colibri." With these composers may be associated De Bréville (b. 1861), Ropartz (b. 1864), composer of the well known "Berceuse," and De Séverac (1873–1921).

Debussy.—The startling harmonic innovations of Debussy have exercised a strong influence upon the music and the songs not only of France but of Europe, a fuller understanding of his work having proved that what was once thought incoherent or experimentary in his scheme is perfectly logical and of undeniable beauty. He discovered a pathway which had not been trodden before, and explored it so thoroughly that little is left there within the limits he prescribed for himself, for other seekers. The delicacy and finish of his work, in which the smallest touch tells, is remarkable, as well as the skill with which the notes carrying the words are interwoven into the fabric of the music. The method is Wagner's but the style is Debussy's who makes it seem that it was made for the French language and no other. Only in the early songs and those in *L'enfant prodigue* is his vocal line melodic. Debussy is certainly the greatest of the impressionists.

The following selection from his 48 songs exhibits the extent of his range and the variety of his style:—"Je tremble en voyant son visage," "La flûte de Pan," "Recueillement," "Clair de lune," "Fantoches," the songs in *Ariettes oubliées,* the three Villon Ballades and the terribly powerful "Noël des enfants qui n'ont plus de maison," composed in 1915. Others will be found in the excellent selection *Douze chants* (Durand Fils, Paris). Those who wish to understand what is meant by Debussy's whole-tone scale, "atonality" and "modern music" will find all clearly explained in Dr. Walker's article on Debussy and more fully in Dr. Dyson's article "Harmony" in *Grove's Dictionary of Music,* 1927–28, and in his book *The New Music* (Oxf. Univ. Press, 1924).

Ravel (b. 1875) is a master of clear and effective delineation. What he aims at he achieves. Debussy suggests, Ravel defines, but his definitions are difficult both to play and to sing. His most characteristic songs are the sets *Scheherazade* and the *Histoires naturelles,* the latter a series of brilliant pictures, full of elaborate and effective detail; of these "Le Paon," "Le Cygne" and "Le Martin-pêcheur" are the best known.

Italy.—Italy, absorbed in opera, has not contributed much that is likely to have permanent value to 19th century song, but the finished work of Sgambati (1843–1914) is worth knowing. He composed more than 40 songs, of which *Four Melodies,* Op. 35, and the setting of the old Italian folk-song "Separazione" may be cited as characteristic. Respighi (b. 1879) studied with Rimsky-Korsakov and Max Bruch, but his songs are individual—modern but not eccentric. Among them are "Nebbie," five charming "Canti all' antica," and the dainty "Stornellatrice." His pupil Pizzetti (b. 1880) in "Inpastori," with its fine modal character, effective declamation and cross rhythms has composed a remarkable song full of interest for both singer and pianist. Malipiero's daringly modern songs fall under the category of those which are not included in this article. In Spain the "Three melodies" and particularly the very striking arrangements of seven "Canciones populares" of Manuel de Falla (b. 1876) deserve special mention: as also a collection of 14 old Spanish airs of the 17th and 18th centuries arranged elaborately and with singular insight by Joachin Nin. The composer includes in each volume a valuable introduction—in French as well as Spanish.

Russia.—Russian song deserves more attention than can be given to it here. Since Glinka (1804–1857) released it from Italian influences, and by impregnating it with the spirit and the idiom of the folk-song, made it, at least in his own work, national, it has steadily increased in importance. There is a fairly large store of good songs by Russian musicians, but they are only in part Russian, their general conception and, to a large extent, their technique being derived from the masters of the German Lied; they represent a hybrid art, which, though full of interest, pales beside the entirely Russian work of one man of genius, Moussorgsky (1835–81). Through him, in his songs as much as in his operas, it seems as if the very heart of the strange Russian people were laid bare. His style is sometimes undisciplined, his realistic painting sometimes crude—natural in an art where colour counts for more than line—but there the pictures stand, throbbing with life, memorable. Many a village tragedy is the subject of his song; Death himself appears, terrible but kind; but Moussorgsky can also sing, no one more tenderly, of the cradle and the nursery; there is humour and satire too. Of the romantic sentiment, characteristic of Germany, there is no trace. In the music of Europe to-day, he has proved a potent influence, as having opened the doors of song to admit subjects hitherto thought impossible or unsuitable to set. Of his 40 or 50 songs most are definitely melodious; in others the voice part approximates to the rise and fall of the voice in speech; in all strong rhythm is an outstanding feature. In his last years he composed the four *Dances of Death* and the cycle of six songs *No Sun,* which rank among the most intensely moving songs ever written, tragically sad, but full of beauty. Examples: "Jeremouschka's Cradle Song," "Little Star, where art thou?" "Savishna" (story of the village idiot), "Gathering Mushrooms" and "Hopak" (both on the subject of "La Maumariée" of French folk-song), "Serenade" and "Trepak" (from the *Dances of Death*), *The Nursery* (seven songs about children). Moussorgsky was one of the four whom Balakirev (1837–1916) drew together to form with himself a "nationalist" band of composers. The others were Borodine (1834–87), César Cui (1835–1918) and Rimsky-Korsakov (1844–1908).

Borodine's "Romance" and "The Sleeping Beauty," Cui's "Hungersong," Rimsky-Korsakov's famous "Hindu song," "Believe me not" and Zuleika's song are all good. To this group of composers must be added the names of the more cosmopolitan Tschaikovsky, Rachmaninov, Grechaninov and Glazunov. Tschaikovsky's "Nur

wer die Sehnsucht kennt" is probably the best of his numerous songs; "The Dreary Steppe" and "Slumber Reigns" are characteristic of Grechaninov; Rachmaninov's "To the Children" is truly Russian and of rare tenderness and beauty.

Medtner (b. 1879), a Russian composer of German descent, is in his music both German and Russian. He has composed songs in both languages, orthodox in form, but elaborate in texture, difficult to play and, at first, to understand, but both on musical grounds and for their serious import well worth unravelling. They are the work of an impressive and forceful personality, not making experiments, but recording convictions. If a successor to Brahms were to be named, it would certainly be Medtner. Among his Russian songs may be cited "Whisp'ring Nature faintly stirring," "O'er thee I bend," and "I have come to say, Good-morning" Op. 24, "The Singer" and "The Muse" (Pushkin) Op. 29, "The Valse" and "To the dreamer" (Pushkin) Op. 32, "Sleepless Nights" (Tutchev) and the Valse, Op. 37; among his settings of Goethe, "Die Spröde," "Die Bekehrte" and "Einsamkeit"; of Nietzsche, "Verzweiflung"; of Eichendorf, "Winternacht," and of Chamisso, "Die Quelle" and "Frisch gesungen."

England.—The beginnings of English song have already been alluded to in speaking of Dowland, Campion, Rosseter and Jones. The subsequent work of H. Lawes, and his contemporaries William Lawes, Coleman and Wilson, was unpretentious and simple. Gems here and there, such as "Gather ye rosebuds" (W. Lawes) and others contained in two small vols. edited by Dolmetsch (Boosey), are the student's reward for a good deal of uninspired and tentative work, in which the main object of composers was to "follow as closely as they could the rhythmical outlines of non-musical speech: they listened to their post friends reciting their own verses and then tried to produce artificially exact imitations in musical notes," (Ernest Walker, *History of Music in England*, p. 130), producing what was neither good melody nor good declamation.

Such work, in spite of Milton's Sonnet to H. Lawes, could only have a passing vogue, especially with a Purcell so near at hand to show the world the difference between talent and genius, between amateurish effort and the realized conceptions of a master of his craft. Songs like "Let the Dreadful Engines" and "Mad Bess of Bedlam" reach a level of dramatic intensity and declamatory power, which is not surpassed by the best work of contemporary Italian composers.

"I attempt from love's sickness to fly" is so familiar in its quiet beauty, that we are apt to forget that melodies so perfectly proportioned were quite new to English art (though Dr. Blow's "The Self-banished" deserves to stand side by side with it). Monteverde's "Lament of Ariadne" has already been alluded to, and it is interesting to contrast its emotional force with the equally intense but more sublime pathos of Purcell's "Lament of Dido," in which song a ground bass is used throughout. The "Elegy on the Death of Mr. John Playford" (quoted in full by Dr. Walker, p. 176 of his history) exhibits the same feature and the same mastery of treatment. The "Morning Hymn" is scarcely less remarkable, and has likewise a ground bass. A large collection of his songs is to be found in the last volume (published in 1928) of the Purcell Society's Edition, edited by Sir Arthur Somervell (Novello). Purcell died, aged 37, in 1695; Bach and Handel were then but ten years old, and Scarlatti, born in 1658, had still 30 years to live—facts of which the significance may be left to speak for itself.

It is among the ironies of musical history that so great a beginning was not followed up. There are echoes of Purcell, stronger ones still of Handel, in the generation that succeeded him, in Croft, Greene and Boyce; but they quickly died away. From the death of Purcell to the Victorian era there is no consistent development of artistic song that is worth recording in detail. Arne, it is true, composed many fine songs that deserve to be better known; those which have survived are mostly of the melodious order, still acceptable for an air of freshness and gracefulness that marks them as his own, *e.g.*, "Where the Bee sucks," "Blow, blow thou winter wind" and "Lovely Phyllis." Song writers that followed him, Bishop, Shield, Hook, Dibdin, Storace, Horn and Linley (the elder), were all prolific melodists, who have each left a certain number of popular songs by which their names are remembered, and which are worth hearing occasionally, but there is little attempt to advance in new directions, no hint that song could have any other mission than to gratify the public taste for tuneful melodies allied to whatever poetry, pastoral, bacchanalian, patriotic, or sentimental, lay readiest to hand.

A good song appeared now and then, but seldom of serious import. Who can wonder at the delight with which England welcomed the songs of Mendelssohn? It was in his school of Leipzig that Sterndale Bennett (1816–1875), the first serious composer of songs in England for nearly a century, received his training. His output and range are small, but the quality of his work is delicate and individual. "To Chloe in Sickness," "Dawn, Gentle Flower," "Gentle Zephyr," struck a note that was new in English song. But he gave to his country a new ideal. Sullivan (1842–1900), more original, more richly endowed than Bennett, was also trained at Leipzig. Though his reputation has suffered from songs which satisfied the public rather than his own ideals, there are many which have real value and will live when the others are forgotten, *e.g.*, his settings of Shakespeare's lyrics ("O Mistress mine," "Orpheus with his Lute," "Where the Bee sucks"), of Tennyson's cycle *At the window* (in which the influence of Schubert is clear), "Tears, idle tears" and "Swallow, Swallow, flying South," and of George Herbert's "Sweet day, so cool," in all of which the touch of genius is unmistakable.

It is obvious from songs like these and from the occasional appearance of others, such as Hatton's "To Anthea," Salaman's "I arise from dreams of thee," Clay's "Songs of Araby" and "The Sands of Dee," that new ideals were in the air. In their further realization the increasing familiarity of the musical public with the masterpieces of German song may be reckoned as an important factor.

Parry and Stanford.—In the early 80's, when Parry (1841–1918) and Stanford (1852–1924), who was also at Leipzig, appeared, it was seen that song was at last taking its proper place in musical art. Parry's early songs are delightfully fresh and melodious (*e.g.*,"The Poet's Song," "On a day, alack the day," "Why does azure deck the sky?"). The three stirring "Anacreontic" odes mark the transition to that individual style which made the appearance of "Prometheus Unbound" one of the landmarks in England's musical history. He composed about 150 songs in all, the bulk of which are in the 12 volumes of *English Lyrics*. Breadth, dignity and sincerity, with a nobility of thought and feeling characteristic of the composer, mark the serious numbers (*e.g.*, "Through the Ivory Gate," "When we two parted," "Armida's Garden"). Equally characteristic are those in which he is boisterous or humorous as in "Crabbed Age and Youth," "The Laird of Cockpen," "Follow a Shadow"; or atmospheric, as in "Dirge in Woods" and "A Fairy Town" or in light and happy vein, as in "Ye Little Birds," and the entirely charming "A Lover's Garland." With all the good qualities of Parry's songs something in the majority of them is lacking, which may perhaps be described as that intimate lyric note in which heart and voice and instrument sing together. The melodic freshness of his early days grew less in the increasing awkwardness of his piano technique, and, perhaps, in the determination at all costs to have his word-declamation right. In this he was entirely successful, setting an example which has been of great value to English song.

Stanford composed about 150 songs. If the settings of the poems from George Eliot's *Spanish Gypsy*, Op. 1, are placed beside the songs of the "Elfin Pedlar," probably the last he composed, it is seen at once that the harmony which adorns the melodies of the former is singularly rich, and that in the latter it is reduced to the barest minimum—and yet it suffices. This gives us the trend of Stanford's work in song—increasing mastery of his resources of technique through the severe principle of economy, not two notes where one will serve. If the expressive colour of "The radiant Dark," is fine, the astonishing simplicity of "Spring" is perhaps the greater achievement. Between these poles in the long list of Stanford's songs every variety of colour and complexity will be found, but no unduly lavish display. In the work of no composer are the means more perfectly suited to the

ends. Arresting songs could be cited in many styles, especially those in *An Irish Idyll* (Moira O'Neill). There in six pieces of rarest beauty he has portrayed against a background of Irish wind, sky, mountain burn and loch, all that is most lovable and most deep in the Irish character, its wistfulness and its pathos, its sunshine and gloom, its seriousness and humour, with a poetical and imaginative power of a kind which is unique. In these will be seen the sureness and the delicacy of his touch not only on the spirit of each song but on the exact words with which it is conveyed. Poetry and music are fused without sacrifice on either side; the unity is complete. In further illustration may be cited the "Corsican Dirge," the remarkable ballads, "La Belle Dame sans merci" and "The Pilgrimage to Kevlaar," also "Three Cavalier songs" (Browning), "A soft Day," "The Pibroch," "The Chapel on the Hill," "Easter Snow," "The Monkey's Carol," "Grandeur," "Daddy-long-legs." No less masterly are his arrangements of Irish folk-songs of which there are four volumes.

Parry and Stanford lived to see many results of their influence and example. No one, however, among the younger composers has produced a body of songs equal in importance to either of theirs. It seems as if the impetus they gave to song on classical lines has already spent its force; if this is true, it is also true that no song composer has arisen with sufficient power and imagination, and, what is also essential, sufficient understanding of the fundamental needs of the voice, to convince the world that the new song is better than the old. The result is that though many musicians have written songs, only a few are song-composers. Of these latter Somervell (b. 1863) is one who has followed the bent of his own genius and resisted the temptation to experiment with novelties that were alien to it. He has produced a body of work characterized by sincere and tender feeling, instinct with a quiet beauty which is individual and charming. Larger qualities appear in the admirable cycle from Tennyson's Maud, in "The Shropshire Lad," "James Lee's wife," and "Love in Springtime" (the last named containing the singularly beautiful "Young Love lies sleeping"). "The Shepherd's Cradle Song," "Once at the Angelus," "When I am dead, my dearest," and "Weep ye no more, sad Fountains," "As through the Land" (2nd setting in E♭) and the dainty settings of some of Blake's *Songs of Innocence,* deserve to be remembered. They are real songs, grateful to sing and without pretentiousness or pose. Somervell has arranged many folk-songs, in *Songs of the Four Nations* (Cramer), and two volumes of *Welsh Folk-songs* (Boosey), with notable skill, taste and sympathy.

Roger Quilter.—The songs of Roger Quilter (b. 1877) are also grateful to sing, especially the settings of Shakespeare's lyrics and of seven Elizabethan lyrics; in the former "Blow, blow thou Winter Wind," and "It was a Lover and his Lass" and in the latter "Weep ye no more," "Damask Roses," and "Fair House of Joy," in spite of some syllabic inexactitudes, are specially good. A vein of wistful sentiment or quiet brooding as in "A Land of Silence," "A Last Year's Rose," pervades a good deal of his later work and appears too in his arrangement of "Drink to me only with thine eyes," in which the accompaniment is his own harmonic meditation on that lovely air and verse. In "To Daisies," "Now sleeps the Crimson Petal" and "Love's Philosophy," he has composed three love-songs in different styles and of undoubted beauty.

Vaughan-Williams.—A strong personality is felt in the songs of R. Vaughan-Williams (b. 1872), whose "Silent Noon" (Rossetti) holds a place among the masterpieces of lyrical song. He has composed many songs, all revealing imaginative qualities of an unusual order and unquestioned sincerity. He is bent on getting himself expressed at whatever cost, and has experimented in many styles, giving the impression that neither in the voice nor in the piano has he quite found the medium that he wants. Beauty for its own sake, the sensuous element in music, has little appeal for him; he is introspective rather than lyrical. There is something in his work that is elemental, and at bottom simple, as in the folk-songs of his country, of which he has arranged many with singular insight; "Bushes and Briars" and "A bold young Farmer," are felt not as arrangements, but as original work, so entirely has he absorbed their spirit (*see* his volume of *Folk-songs from the Eastern Counties*). The modal influences of the folk-song contribute much to the atmosphere which pervades the deeply impressive cycle *Wenlock Edge* (from Housman's *Shropshire Lad,* for tenor voice, string quartet and piano), and *Five Mystical Songs* (George Herbert) for solo, chorus and orchestra, of which the rapt intensity of "The Call" and the relentless force of "Antiphon" are equally arresting. Among his songs for voice and piano may be cited "Orpheus with his Lute," "The Roadside Fire," and others from the two volumes of Stevenson's *Songs of Travel,* "The Sky above the Roof," "The Mill Wheel" and "Linden Lea," which has the freshness of a folk-song. Whether the coming generation will set these aside and take to its heart the composer's later style, with its uncompromising modal polyphony, is an obvious question to ask and a dangerous one to answer.

In a survey of modern English song the salient fact is not that the store has grown so large, but that so many composers have contributed to it. It must suffice, therefore, to add to what has been written of individual composers a list of songs, necessarily incomplete, which have established their worth or deserve attention. Those which appear in a collection already published under the auspices of the Society of English Singers, *Fifty modern English songs* (Boosey and Co.) are not included. The reader is reminded that songs of the most modern type are not under review.

Bibliography.—Arnold Bax, *Five Irish Songs,* of which "The Pigeons" is a masterpiece of delicate illustration; E. C. Bairstow, "Orpheus with his Lute," "The Oak Tree Bough" (a grim picture), "I heard the learned Astronomer"; A. Benjamin, "Phyllis milking her Flock," "The Piper," "Diaphenia"; E. Bullock, *Brittany;* George Butterworth, Bredon Hill and other songs from *A Shropshire Lad* of which "Is my Team ploughing" is a gem; also a volume of English Folk-songs (arranged); Granville Bantock, "Yungyang" and "The Feast of Lanterns"; M. Besly, "Time yon old Gypsy Man" and "Epitaph"; Frank Bridge, "Love went a-riding," "Go not, Happy Day," "Come to me in my dreams"; Olive Carey, "Melmillo," "A Rondel" and a volume of English folk-songs (arranged); B. J. Dale, "O Mistress Mine" and "Come away death" (with viola obligato); Harold Darke, "Uphill"; Malcolm Davidson, "A Christmas Carol"; Thomas F. Dunhill, *The Wind among the Reeds,* a cycle (including "The Fiddler of Dooney" and "The cloths of Heaven") and "The Haymakers' Roundelay"; Frederick H. Cowen, "At the mid-hour of Night," "The Birthday," "Onaway, awake, Beloved"; H. Walford Davies, "When Childer plays," "The Bells of Bethlehem" and *Songs of Innocence* (Blake); Gustav Holst, *Hymns from the Rig Veda* (especially "I, the Queen of all," "The Heart worships," and "Four Songs for Voice and Violin"); a volume of "Folk-songs from Hampshire" (arranged); Elgar, *Sea pictures;* Edward German, "Who'll buy my Lavender," and "It was a lover and his lass"; Armstrong Gibbs, "Nod," "Silver," "The Fields are full," and the humorous "With Five Eyes"; Alan Gray, "Tiger, Tiger," and "Eleuloro"; Ivor Gurney, two cycles *Ludlow and Teme, The Western Playland* (for tenor and baritone respectively, with piano and string quartet), "Edward" (Scotch ballad), "Spring," "Desire in Spring" and "Sleep"; Hamilton Harty, "The Rachray Man," "Lane o' the Thrushes," "A Drover"; W. H. Hadow, "Under the Hill" and "Bright is the Ring of Words"; Herbert Howells, "King David," "Mally O" and Gavotte; Herbert Hughes, 2 vols. of *Irish Country Songs* (arranged); John Ireland, "Spring Sorrow," "If there were dreams to sell," "The Vagabond," and "Santa Chiara"; F. Keel, "My Sweet Sweeting," *Salt Water Ballads* (2 sets) and "Helen of Kirconnell," arrangements of "Elizabethan Love Songs" (2 vols.); Peterkin, "The Galliass"; Cyril Scott, "The White Knight"; Martin Shaw, "Hefle Cuckoo Fair," "Song of the Palanquin Bearers," "Cuckoo"; Thiman, "The Silver Swan" and "As Joseph was a-walking"; Ernest Walker, "Corinna goes a-maying," "Snowdrops," and "Bluebells from the Clearing"; Gerrard Williams, "Song in Autumn" and "Moon"; Peter Warlock, "Lullaby," "Piggesnie" and "That ever I saw"; Charles Wood, "Ethiopia Saluting the Colours," "The dead at Clonmacnois," "At Sea," and "Denny's Daughter"; 25 *Irish Folk Songs* (Boosey) (arranged); Maude V. White, "To Mary," "Go, lovely Rose," "Absent yet Present," "So we'll go no more a-roving," and "Mary Morison."

In *Grove's Dictionary of Music* Mrs. E. Woodhouse's article "Song," gives a full bibliography of the whole subject of song and folk-song, country by country. In the edition of 1928 further information will be found in the articles upon the chief composers of songs and in the catalogue of their works which in most cases is appended with dates. The following list is mainly of books which the present writer has found most useful: Ambros, *Geschichte der Musik* (1862–82); Reissmann, *Das deutsche Lied* (1861; rewritten as *Geschichte des deutschen Liedes,* 1874); Schneider, *Das musikalische Lied* (1863); *Oxford History of Music* (1901–05) vols. iii. iv. v. and vi.; W. H. Hadow, *Studies in Modern Music,* 2 vols. (1895–96); Parry, *Art of Music* (1897); Max Friedländer, *Brahms' Lieder* (1922); Oscar Bie, *Das deutsche Lied* (1926); E. Walker, *History of Music in England* (1907); Dr. Fellowes, *The*

English Madrigal composers (1921); E. Dyson, *The New Music* (1924); Boehme, *Altdeutsches Liederbuch* (1877); Reimann's *Das deutsche Lied,* 2 vols. *Das deutsche Geistliche Lied,* 6 vols.; Weckerlin, *Echos du temps passé,* 3 vols. (1855). (W. Fd.)

AMERICAN SONG

For the purposes of this article the expression "American song" will be used to cover the history and development of song writing in the United States by native-born composers. Due to the heterogeneous ancestry of her inhabitants, America has produced, until comparatively recently, few songs that can be considered distinctly indigenous. The singers of America for generations have ranked among the greatest; her foremost song-writers, however, with but rare exceptions, have proved second-rate measured by the standards of the Old World. This lack of musical atmosphere is undoubtedly caused not only by the mixed nationalities of Americans, but also by the fact that America's attention was focussed necessarily at first on producing the bare necessities of life and later to extending her commerce with other countries.

According to the best available authorities, Francis Hopkinson (1737–91) was the first native-born American composer. His "My days have been so wondrous free," composed in 1759, is the earliest known secular song by an American. It is interesting to note the natural English flavour that permeates most of Hopkinson's songs. Almost a century elapses before we encounter the songs of another American composer, those of Stephen Collins Foster (1826–64), unless, of course, we consider as song-writers such compilers of tune-books and composers of hymns as James Lyon (1735–94), William Batchelder Bradbury (1816–68), Thomas Hastings (1787–1872), and Lowell Mason (1792–1872).

Despite the ever-diminishing attitude of patronage of some musicians towards his songs, Stephen Foster stands as one of the few representative American composers. His "Old Folks at Home," "Nelly Bly," "Old Uncle Ned," and "My Old Kentucky Home" are among the best known of his songs. Following him come George Frederick Root (1820–95), George Frederick Bristow (1825–98) (better known for his work in larger forms, but a splendid, sincere writer of songs), Harrison Millard (1830–95) and James Remington Fairlamb (1838–1908). These men belonged to approximately the same period; yet an examination of their work shows a startling lack of similarity. For example, what could be more widely separated than Foster's "Old Folks at Home," Fairlamb's "Little Blue Pigeon," an aria from Bristow's "Rip Van Winkle," Millard's "Waiting," and "Tramp, Tramp, the Boys Are Marching," by which Root is best remembered? We see here a curious factor: the English element is gradually being overshadowed by the Teutonic, Scandinavian, and later on French and Latin.

The era from the Civil War to the end of the 19th century marks the gradual progress of the American song-writer, culminating in the titanic figure of Edward MacDowell, who composed "The Sea," "Thy Beaming Eyes" and "Long Ago." Lack of space permits the mention of only a few lyric composers of this period, the foremost being:—Dudley Buck (1839–1909), "Fear Not Ye, O Israel"; Homer Newton Bartlett (1846–1920), "Thy Dear Eyes"; Arthur William Foote (1853–), "I'm Wearin' Awa'"; George Whitefield Chadwick (1854–), "Allah"; Wilson George Smith (1855–), "If I But Knew"; James Hotchkiss Rogers (1857–), "At Parting"; Clayton Johns (1857–), "I Love and the World Is Mine"; Edgar Stillman Kelley (1857–), "Israfel"; Harry Rowe Shelley (1858–), "Love's Sorrow"; Charles Beach Hawley (1858–1915), "Because I Love You Dear"; Charles Whitney Coombs (1859–), "In the Dark, in the Dew"; Henry Louis Reginald de Koven (1859–1920), "O Promise Me"; Gerrit Smith (1859–1912); William Arms Fisher (1861–), "Under the Rose"; Arthur Battelle Whiting (1861–), "Fuzzy-Wuzzy"; R. Huntington Woodman (1861–1928), "An Open Secret"; Ethelbert Woodbridge Nevin (1862–1901), "The Rosary"; Horatio William Parker (1863–1919), "Once I Loved a Maiden Fair"; William Harold Neidlinger (1863–1924), "The Birthday of a King"; Frederick Field Bullard (1864–1904), "Stein Song"; William Victor Harris (1869–), "The Hills o' Skye."

Several of these composers are writing songs at present (1929), but they did most of their work before the close of the 19th century.

From the beginning of the 20th century to the present time, the tendency in American song writing has been towards a more distinctly national flavour rather than to reflect European traditions. The composers in the following list belong to the 20th century rather than to the 19th:—Sidney Homer (1864–), "Requiem," "Banjo Song"; Harvey Worthington Loomis (1864–), "In the Foggy Dew"; Henry Franklin Belknap Gilbert (1868–1928), "Pirate Song"; Henry Hadley (1871–), "The Face of All the World Has Changed"; Charles Fonteyn Manney (1872–), "Consecration"; Arthur Farwell (1872–), "Drake's Drum"; Daniel Gregory Mason (1873–), "Russians" (a cycle); Edward I. Horsman (1873–1918), "The Bird of the Wilderness"; William Armour Thayer (1874–), "My Laddie"; Charles Gilbert Spross (1874–), "Will o' the Wisp"; Frederic Ayres (1876–1926), "Sea Dirge"; John Alden Carpenter (1876–), "Gitanjali" (a cycle); Oley Speaks (1876–), "On the Road to Mandalay," "Sylvia"; Chester Barker Searle (1876–), "The Rose and the Heart"; Louis Campbell-Tipton (1877–1921), "A Spirit Flower"; David Stanley Smith (1877–), "Portraits" (a cycle); Frank La Forge (1879–), "To a Messenger"; Stanley R. Avery (1879–), "Song of the Timber Trail"; Charles Wakefield Cadman (1881–), "From the Land of the Sky-Blue Water"; Franklin Morris Class (1881–1926), "To You, Dear Heart"; Arthur Bergh (1882–), "The Congo"; Geoffrey O'Hara (1882–), "The Wreck of the Julie Plante"; Bainbridge Crist (1883–), "Chinese Mother-Goose Rhymes" (a cycle); Charles Tomlinson Griffes (1884–1920), "An Old Song Resung"; Deems Taylor (1885–), "Captain Stratton's Fancy"; Wintter S. Watts (1886–), "Miniver Cheery"; Harry Reginald Spier (1888–), "Ultima Rosa"; Arthur Walter Kramer (1890–), "The Faltering Dusk"; Robert Armbruster (1896–), "The High Barbaree"; Oscar J. Fox, "The Hills of Home," "Rounded Up in Glory" (cowboy spiritual); J. Bertram Fox (1881–), "Ich wandre durch die stille Nacht."

Special tribute, as they have developed a type distinctly their own, should be paid such negro composers and compilers as Henry Thacker Burleigh (1866–), negro spirituals; J. Rosamunde Johnson (1873–), "Nobody Knows the Trouble"; William C. Handy (1873–), collection of Blues; Robert Nathaniel Dett (1882–), religious folk-songs of the negro as sung at Hampton Institute.

In America, as in no other country, the women are rapidly approaching the men in the excellence of the songs they are writing. Some of the most prominent women composers of American birth are:—Mary Turner Salter (1856–), "The Cry of Rachel"; Carrie Jacobs Bond (1862–), "A Perfect Day"; Margaret Ruthven Lang (1867–), "Irish Love Song"; Amy March Beach (1867–), "The Year's at the Spring"; Harriet Ware (1877–), "The Cross"; Mabel Wheeler Daniels (1878–), "At Daybreak"; Gena Branscombe (1881–), "Hail Ye Tyme of Holiedayes!"; Lily Teresa Strickland (1887–), "Since Laddie Went Awa'"; Marion Bauer (1889–), "The night has a thousand eyes"; Mana Zucca (1891–), "The Big Brown Bear"; Rhéa Silberta (1900–), "Wild Geese."

What is undoubtedly a purely American type is the so-called popular song, often referred to as "sob-ballad." Some of the leaders in this field have been:—Daniel Decatur Emmett (1818–1904), "Dixie's Land"; Charles K. Harris (1868–), "After the Ball"; Theodore F. Morse (1875–1924), "Blue Bell"; Frederick W. Vanderpool (1877–), "If winter comes"; Ernest R. Ball (1878–1928), "Love Me and the World is Mine," "Mother Machree"; Jerome David Kern (1885–), "Who?," "Left all alone again Blues"; Irving Berlin (1888–), "An Orange Grove in California"; George Gershwin (1898–), "Blue Monday," "Lady, be good!"

The five outstanding names among American song-writers are:— Francis Hopkinson, Stephen Foster, George Whitefield Chadwick, Edward MacDowell and Deems Taylor. Hopkinson

produced his best work in 1788, Foster in 1850–51, Chadwick shortly before 1900, MacDowell around 1900, and Taylor around 1920. The lapses of time between these really outstanding song-writers are becoming less, which presages well, if the present rate of diminution continues. (R. WER.)

The following list of composers includes foreign-born, whose work was entirely or largely in the United States: Charles Martin Loeffler (Alsace, 1861), "To Helen"; Victor Herbert (Ireland, 1859–1924), "The Call to Freedom"; Carl Busch (Denmark, 1862–), "The Sea Hath Its Pearls"; Walter Damrosch (Germany, 1862–), "Danny Deever"; Louis Victor Saar (Holland, 1868–), "To One I Love"; Bruno Huhn (England, 1871–), "Invictus"; Cecil Forsyth (England, 1870–), "O Red Is the English Rose"; Arthur Penn (England, 1880–), "Smilin' Through"; Richard Hagemann (Holland, 1882–), "At the Well."

SONG BIRDS, birds whose vocal expression resembles music. Technically the super-family *Oscines,* "song birds," includes nearly all the families of perching birds (*Passeres*), about five thousand species. Among the perching birds it excludes such groups as the Old World Pittas, and the New World flycatchers (*Tyrannidae*) each species of which has a characteristic word, as "phoebe," "chebec," or the more melodious "pee-wee," in place of a song. The distinguishing mark of the *Oscines* is the possession of four or more pairs of muscles controlling the syrinx, the organ of voice in birds; this brings within the super-family the crows and jays, many of which have rich and supple voices, some of them very human in tone, but in the more popular sense they are not "song birds" because they lack the rhythm and melody which the true songsters possess.

Many of the finest singers are found in the northern temperate zone, among the thrushes (*Turdidae*) and their close kindred the Old World warblers (*Sylviidae*), families which include the European blackbird, the song thrush, the nightingale and blackcap. The nightingale is the most famed of all song birds, though poets singing the praises of Philomela have mistaken the sex of the singer, as Milton, who speaks of "her sad song." The nightingale's summer range extends from southern England through Europe eastward to the Balkans and Asia Minor, and southward to northwest Africa. Its song, writes Hudson, "is exceedingly beautiful; its phrasing is more perfect than that of any other British melodist; and the voice has a combined strength, purity and brilliance probably without a parallel." In Scandinavia, Russia and Siberia it is replaced by the slightly larger eastern nightingale, the bird known to Linnaeus. The blackbird, found throughout Europe, a black thrush with an orange bill, has "a beautiful mellow voice," according to Hudson, who speaks of the peculiar soft, rich melodious quality of the sound, and the placid, leisurely manner in which the song is delivered. As Browning noted, the song thrush "sings each song twice over," or, more truly, each theme or musical element of his song. The missel thrush is best known as a winter singer; from midwinter until spring, as Hudson writes, "his music is most noteworthy. Its loudness and wild character give it a wonderful impressiveness." The European robin redbreast, one of the dozen British birds so well known as to have a personal name, belongs to the same gifted family; Burroughs has written well of his pure and piercing tones, "piercing from their smoothness, intensity, and fulness of articulation." Among the Old World finches (*Fringillidae*) many are good singers; the bullfinch has the best voice, with the mellow contralto quality of the blackbird. In another musical family, the larks (*Alaudidae*), the skylark is pre-eminent, almost as dear to poets as the nightingale; but the best description is in Hudson's rhythmical prose: "I have listened to it by the hour, never wearying nor ceasing to wonder at that mysterious beautiful music which was like the heavenly sunshine translated into sound; subtle, insistent, filling the world and the soul, yet always at a vast distance, falling like a lucid rain."

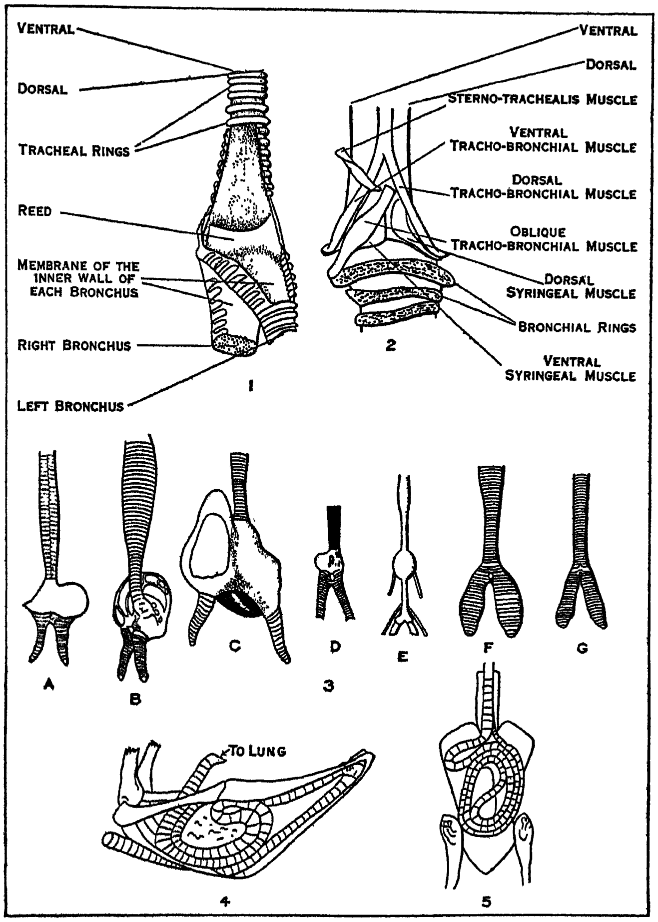
Some of the finest New World singers belong to the thrush family. Among the thrushes of the eastern States are the wood thrush, whose clear, bell-like tones, carrying to a great distance, are linked together by varied notes heard only near at hand, some like a twanged mandolin string; the hermit thrush, still more eminent for richness of tone, melody and the expressive passion and length of his song; the veery, whose circling choral thrills by the richness of its overtones; the gray-cheeked thrush, with a similar choral turning upward at the end; the olive-backed thrush, whose song somewhat resembles the hermit's; the robin, with a clear, happy tone and an endless variation of themes, which he embroiders together for a half hour without stopping; and the bluebird, with pure contralto tones, but less melodic power than the other New World thrushes. Many of the North American finches are gifted singers. The rose-breasted grosbeak has a rich contralto voice, a fine melodic sense, and something of the passionate expression of the hermit thrush; unlike the robin, he sings a single, definite melody, repeated at intervals. The purple finch has contralto tones, in contrast to the high notes of the goldfinches, who gather in a tree top and sing in chorus. Many American sparrows are good singers, the song sparrow being the best endowed as a melodist, almost every song sparrow having his individual song, with a marked sense of rhythm. The fox sparrow sings in early spring a clear, rich melody. The song of the white-throated sparrow has a dactyl rhythm, prefaced by one note, either above or below the monotone dactyls. The white-crowned sparrow opens his song with three notes, like a higher echo of the meadowlark's song, followed by a short trill. In the family *Icteridae* the bobolink, whose wild, sweet rippling song is uttered as he flies across a meadow, is the best singer; the orioles, with rich tones, and expressive themes, suggest eloquent speech rather than song. The New World wood warblers (*Mniotiltidae*), most of which are irrepressible singers on the spring migration, have distinctive themes, but only a few, like the water-thrushes and the Canadian warbler, are melodious singers. The family to which the wrens belong (*Troglodytidae*) includes noted singers like the mocking bird, so famous in the songs of the South, and the brown thrasher which sings each theme twice over from a conspicuous tree top; the rock wren of the western mountains; the clear voiced Carolina wren; the tinkling winter wren of the northern hills; and the widely distributed long-billed marsh wren, who is wafted into air by the vehemence of his song. Of the mocking birds of South America Hudson has written eloquently. Australia has gifted mockers, like the lyre-bird, but they are not true song birds. (C. JOH.)

SONG OF BIRDS. Though aesthetically we ascribe the power of song only to such birds as produce a series of melodious notes forming a coherent refrain, yet, as they are commonly produced in greatest perfection only in association with reproductive activities, all sounds, musical or otherwise, used to give expression to the emotions during this time are included in the definition "song," in this article, as are mechanically produced sounds when used to express the same emotions. Within recent years there has been much discussion over the exact significance of song. Darwin's theory that it was to charm the female (*see* SEXUAL SELECTION) has been attacked by Eliot Howard, who suggested that bird song was concerned primarily with breeding territory. (*See* BIRD.) E. M. Nicholson, however, has shown that this is only partially true. Many birds normally sing from the most prominent perch in the neighbourhood, and when no perch is available, as with open-country birds like the skylark and bobolink, the song is given in the air.

Voice in birds is produced by modification of the lower end of the windpipe, which forms the *syrinx.* While, however, the dissecting knife reveals the apparatus it leaves us in the dark as to the factors which ultimately produce melodious song; as is shown by the fact that there is no perceptible difference in the syrinx between the nightingale and crow.

The most accomplished performers, like the nightingale, hermit thrush, mockingbird and skylark, are members of the Passeres, or perching birds, which whether "musical" or not, have the most highly developed voice-organ among birds. The syrinx here is a bony box, formed by fusion of the last three or four rings of the trachea, and the uppermost of the semi-rings stiffening the outer walls of the bronchi. Within this box a bony bar, the pessulus, crosses the lower end of the trachea anteroposteriorly, forming

a beam to support a vibratile membrane, the "reed." This reed acts with a fleshly lip on the opposite (outer) wall of the tube, which increases or diminishes the aperture between itself and the reed, so varying the pitch of the note. Sound-production is further aided by as many as seven pairs of muscles running from the windpipe to the ends of the last tracheal, and first bronchial, semi-rings, as shown in the diagram. In all non-passerine birds,



FROM (1, 2, 3) FOWLER, "SUMMER STUDIES OF BIRDS AND BOOKS" (MACMILLAN, LTD.), (4, 5) PYCRAFT, "HISTORY OF BIRDS" (METHUEN)

FIGS. 1–5.—VOCAL MECHANISM OF BIRDS: THE "SYRINX" OF BIRDS (1) Interior of the syrinx; (2) side-view of the syrinx from the outside; (3) the syrinx of some of the ducks forming bony chambers, (A) Mallard, (B) Pochard, (C) Goosander, (D) Steller's Eider, (E) Velvet Scoter, (F) Male and (G) Female Common Scoter; (4) Sternum of a crane; (5) the coils of the windpipe of a Manucode

the syrinx is much less complex in structure, and may have only a single pair of muscles.

Certain modifications of the windpipe must now be mentioned. In surface-feeding ducks, *e.g.*, the mallard, the trachea ends in a large, spherical, bony chamber, present only in the male. Ostensibly its purpose is that of a resonator. Yet the raucous "quack-quack" of this species is uttered only by the female, whose trachea has no "sound-box." In diving-ducks, *e.g.*, the pochard, or the canvasback, this resonator is much larger but its walls are greatly fenestrated, semilunar patches of thin, transparent membrane being stretched between delicate bars of bone. The trachea is considerably widened along the middle. A trace of this is seen in the mallard. In the goosander (merganser), the resonator attains great size, and here, again, the walls are fenestrated. In the male the windpipe displays two marked swellings; the female has only one; while in the allied red-breasted merganser, the male has one tracheal expansion, the female none. In the common scoter the resonator has disappeared, but the bronchi of the male are peculiarly swollen. The relation these modifications have to the voice is not known.

Inflated air-sacs, or air pumped into the gullet, play a conspicuous part in the "love-displays" of birds (*see* COURTSHIP OF ANIMALS), accompanied by sounds peculiar to the occasion. But there is no evidence that they do more than serve as resonators. In all these cases there is a "display" of some sort. The common house-pigeon, for example, when striving to rouse the amorous instincts of his mate, inflates the gullet, at the same time giving voice to the familiar "coo-ing" as he bows down before her.

Instruments of percussion for the production of sound, in place of the voice, are used by widely different species. One of the most striking examples is furnished by the white stork. Several birds will often perform at the same time; but here it appears to be an emotional reflex by no means always associated with courtship. While standing at rest they will suddenly thrust the beak skywards, then begin to snap the jaws together with inconceivable rapidity, at the same time bringing the head backwards till the tip of the beak nearly touches the back, and then forwards nearly to the ground, making a noise like the sound of castanets.

The snipe, in the breeding season, mounts high in the air, descending with a mighty rush, at the same time giving forth a loud note which resembles a goat's bleat. These sounds are produced by vibration of the outermost pair of tail-feathers.

Some woodpeckers such as the British greater and lesser spotted, and the American red-headed, hairy and downy woodpeckers, and the flicker produce rapid drumming notes, by striking the bough of a tree with the beak. They will resort to a corrugated iron roof or telegraph pole in preference to a tree-trunk, because of the louder notes obtainable.

SONNEBERG, a town of Germany, in the republic of Thuringia, situated in a narrow valley of the Thuringian forest, 13 m. by rail N.E. of Coburg. Pop. (1925) 19,156. It is famous for the manufacture of toys.

SONNET. Like most beginnings the genesis of the sonnet is somewhat obscure. On the whole, the most probable account is that it sprang, as the result of endless experiments, from the popular short poems sung, in early mediaeval times, with or without refrain, to musical accompaniment, as the Idyl of Theocritus similarly arose from simple pastoral strains. A very early specimen of the sonnet of a tolerably finished kind, is ascribed to Piero delle Vigne (d. 1249), the famous chancellor of Frederick II., and this poem, alike by its Sicilian origin and by its formal elaboration, is sufficient to prove that a long period of experimenting must have preceded. Time is required both for the *genre* to have reached so far south and for the degree of finish shown by this poem to have been attained. But with every allowance for earlier talent we probably do little injustice if, in accord with the majority of critics, we call Guittone of Arezzo (d. 1294) the "only begetter" of the sonnet as we know it. It was he who firmly established its laws. From his time it was recognized that there must be an "octave," with rhymes (in an unusual notation), a, b, b, a; a, b, b, a, and a "sestet," in which, while some variety is allowed, the final couplet is excluded. Between the octave and the sestet there is a distinct break, and, as a rule, the first quatrain of the octave is, though less strongly, marked off from the second. More important still, in spite of a certain looseness of thought and roughness of style, Guittone established the *unitary* character of the sonnet.

It was the Guittonian sonnet which, in the hands of Dante and Petrarch, became—certain aberrations notwithstanding—the unquestioned model for later Italian writers. Especially as used by Petrarch, in his immortal Laura-poems, it set a standard which the greatest poets could hardly hope to overpass, and it was imitated by such poets throughout the whole of western Europe.

The English Form.—Transplanted to England by Wyatt and

Surrey (it is remarkable that it does not seem to have attracted Chaucer) the sonnet was made universally known by the very popular *Tottel's Miscellany* of 1557, and almost immediately captured the fancy of every poet, great, indifferent, or contemptible. In France, about the same time, it was cultivated with success by Desportes, de Baïf, Pierre de Brach, du Bellay, Ronsard and other writers, whose influence was very strongly felt in England—how strongly has been well shown by Sidney Lee. But in England, for many reasons (one, perhaps, being merely the scarcity of rhymes as compared with their abundance in the Romance languages), the rhyme-system was varied and simplified in endless ways.

For the names of the many sonneteers of this period any history of literature may be consulted. Most of them tried "sequences"—series of more or less connected sonnets; but while some individual poems are of surpassing beauty, few writers succeeded in composing more than two or three that deserve a place in a high-class anthology. Even Spenser was not wholly successful, though he adopted a form which might seem suited to his genius—the rhyme-system, a, b, a, b; b, c, b, c; c, d, c, d; c, c, which reminds us of the stanza of the *Faerie Queene*. Others came gradually to adopt uniformly the especially "English" scheme, a, b, a, b; c, d, c, d; e, f, e, f; g, g; a scheme in which it is immediately obvious that the three quatrains and the "clinching" couplet attain an epigrammatic effect foreign to that of the Petrarchan type.

Milton and Wordsworth.—By the date (1609) of the publication of the supreme examples of the Elizabethan type, Shakespeare's sonnets—which had indeed been probably written long before—the vogue of this style had worn itself out, and the 23 English and Italian sonnets of Milton show, as might be expected, a reversion to a stricter model. Though the poet of the "variously drawn-out" verse of *Paradise Lost* was bound to make no attempt to break the sense at the conclusion of the octave, yet in other respects he conforms (in the main) to the Petrarchan system, and is Italian enough to give us one "caudate" sonnet. Apart from questions of relative merit, the tone of these sonnets is thus altogether different from the Elizabethan. Since his time there have been few endeavours to revive the "English" style. Not that, till much later, the rigid rules were observed. Even the scholarly Gray, in his sonnet on the death of West, allows himself extreme licence; and Cowper's on Mrs. Unwin, beautiful as it is, ends with a couplet. Thus, as the merit of a sonnet is usually in proportion to its strictness, it is perhaps as well that it went out of fashion between 1740 (the date of Gray's sonnet) and 1789 (the date of those of Bowles). The importance of Bowles, again, consists hardly at all in intrinsic worth, but almost solely in the influence he exerted upon Coleridge and Wordsworth; nor are Coleridge's sonnets, few as they are, worth the trouble of reading. It is to Wordsworth that we owe the great and enduring popularity of the form, and possibly even the revived appreciation of Shakespeare's sonnets, which, as is well-known, Steevens refused to reprint on the ground that they were unreadable. Wordsworth, not merely by the surpassing beauty of 20 or 30 of his sonnets, but by his "sequences," is the modern founder of the *genre*. It is true that not many even of his sonnets are quite regular, and that it is not to the "Ecclesiastical Sketches" nor to the "Duddon" series that we look for his best work; but his perception that the form lends itself to the expression of connected thoughts inspired Rossetti in his *House of Life*, Mrs. Browning in her *Sonnets from the Portuguese*, and Meredith in his *Modern Love*, which, though not in the sonnet-form, has much of the character. Since Wordsworth there have never been lacking sonneteers, and at least some of their work has been of great excellence. It is noteworthy how often men not of the highest genius have found in the very constriction of the form "not bonds but wings," and have produced, by a flash of inspiration aided by labour, single sonnets not unworthy to be compared with the best even of Shakespeare's or of Milton's. While, as we saw, Coleridge failed, and while the genius of Shelley was cramped in the "narrow room" (he wrote but one good sonnet, and that not a true one), some great poets, like Keats, and others of a lower order, have moved in it with ease and have attained great heights.

The literature of the subject is large, and but a tithe of it can be mentioned here: for history and criticism Capell Lofft, Leigh Hunt, Mark Pattison (preface to Milton), Trench (preface to Wordsworth), Sidney Les (*Life of Shakespeare*), Lentzner (down to Milton), Addington Symonds, Ashcroft Noble, Theodore Watts-Dunton and T. W. H. Crosland. Good and comprehensive selections also abound, many of them with critical and historical prefaces and notes. Of these we may choose Lofft, Hunt, William Sharp, Waddington, Hall Caine and Tomkinson. But as new sonnets are constantly being written so new selections are constantly being made. (E. E. K.)

SONNINO, SIDNEY Baron (1847–1922), Italian statesman and financier, was born at Florence on March 11, 1847. Entering the diplomatic service at an early age, he was appointed successively to the legations of Madrid, Vienna, Berlin and Versailles, but in 1871 returned to Italy, to devote himself to political and social studies. On his own initiative he conducted exhaustive inquiries into the conditions of the Sicilian peasants and of the Tuscan *métayers*, and in 1877 published in co-operation with Signor Leopoldo Franchetti a masterly work on Sicily (*La Sicilia*, Florence, 1877). In 1878 he founded a weekly economic review, *La Rassegna Settimanale*, which four years later he converted into a political daily journal. Elected deputy in 1880, he distinguished himself by trenchant criticism of Magliani's finance, and upon the fall of Magliani was for some months, in 1889, under-secretary of State for the treasury. In view of the severe monetary crisis of 1893 he was entrusted by Crispi with the portfolio of finance (Dec. 1893), and by energetic measures he averted national bankruptcy, and placed Italian finance upon a sounder basis than at any time since the fall of the Right. Though averse from the policy of unlimited colonial expansion, he provided by a loan for the cost of the Abyssinian War in which the tactics of General Baratieri had involved the Crispi cabinet, but fell with Crispi after the disaster at Adowa (March 1896). Assuming then the leadership of the constitutional opposition, he combated the alliance between the Di Rudini cabinet and the subversive parties, criticized the financial schemes of the treasury minister, Luzzatti, and opposed the "democratic" finance of the first Pelloux administration as likely to endanger financial stability. After the modification of the Pelloux cabinet (May 1899) he became leader of the ministerial majority, and bore the brunt of the struggle against Socialist obstruction in connection with the Public Safety bill. Upon the formation of the Zanardelli cabinet (Feb. 1901) he once more became leader of the constitutional opposition, and in the autumn of the year founded a daily organ, *Il Giornale d'Italia*, the better to propagate moderate Liberal ideas. He was prime minister for a few months in 1906.

On Dec. 2, 1909, Sonnino formed his second ministry. But he did not enjoy the favour of the still Giolittian Chamber, and his cabinet was defeated over the new shipping bill. On March 21, 1910, he resigned.

In the autumn of 1914, he became foreign minister in the Salandra cabinet. He was still foreign minister, under Orlando's premiership, during the Peace Conference, which he attended as second Italian delegate from Jan. 18 to June 19, 1919. On the fall of the Orlando cabinet (June 19, 1919) Sonnino retired into private life. He died on Nov. 24, 1922.

SONORA, a northern State of Mexico, bounded N. by the United States, E. by Chihuahua, S. by Sinaloa and W. by the Gulf of California. It is the second largest State in the republic, having an area of 76,633 sq. miles. Pop. (1910) 265,383; (1921) 275,127, a large part being Indian. The surface of the eastern half of the State is much broken by the Sierra Madre Occidental. The soil of the valleys is fertile, and when it is irrigated sugar-cane, tobacco, maize, cotton, vegetables (especially tomatoes and onions) and fruits are produced. Lack of transportation facilities has been partly relieved by the construction of a branch of the Southern Pacific (American) from Nogales southward to Guadalajara, Mexico City and Mazatlán. Guaymas is the only port of importance on the coast, but it has a large trade and is visited by the steamers of several lines. The capital of the State (since 1882) is Hermosillo (pop. 1910, 14,578; 1921, 14,745), on the Sonora

river, 110m. north of Guaymas, with which it is connected by rail. Other important towns are Nogales, on the American border, and Cananea, an important mining town.

SONS OF LIBERTY, associations which came into existence in the American colonies of Great Britain in opposition to the Stamp Act passed in 1765. They were secret in character, indefinite in organization, radical in temperament. Much of the resistance against British attempts to enforce taxes was organized by them. At times they gathered openly, held parades and dinners, sang liberty songs, burned governors and tax-collectors in effigy and stirred popular enthusiasm. Those in New York and Massachusetts were most active. When the Stamp Act was passed the New York Sons of Liberty appointed the first popular committee of correspondence, adopted the first non-importation agreement, threatened those who used stamps, and protected those who carried on their business on unstamped paper. Members were recruited chiefly from the trade classes, and prominent Whig politicians were usually the leaders. The societies played an important part in spreading a spirit of resistance in preparation for the Revolutionary War.

SOO CHOW, a town in the province of Kiang-su, with a population estimated (1926) at 500,000. It is on the Grand canal to the east of Lake Tai-hu and about 55 m. W.N.W. of Shanghai, with which it is connected by rail. The walls are about 10 m. in circumference and there are many large suburbs. The town was founded in 484 by Ho-lu-Wang, whose grave is covered by the artificial "Hill of the Tiger," in the vicinity of the town.

SOPHIA (1630–1714), electress of Hanover, twelfth child of Frederick V., elector palatine of the Rhine, by his wife Elizabeth, a daughter of the English king James I., was born at The Hague on Oct. 14, 1630. Residing after 1649 at Heidelberg with her brother, the restored elector palatine, Charles Louis, she married in 1658 Ernest Augustus, who became elector of Brunswick-Lüneburg, or Hanover, in 1692. Her married life was not a happy one. Sophia became a widow in the year 1698, but before then her name had been mentioned in connection with the English throne. When considering the Bill of Rights in 1689 the House of Commons refused to place her in the succession, and the matter rested until 1700 when the state of affairs in England was more serious. William III. was ill and childless; William, duke of Gloucester, the only surviving child of the princess Anne, had just died. The electress was the nearest Protestant heir. Accordingly by the Act of Settlement of 1701 the English Crown, in default of issue from either William or Anne, was settled upon "the most excellent princess Sophia, electress and duchess-dowager of Hanover" and "the heirs of her body, being Protestant." Sophia watched affairs in England during the reign of Anne with great interest, although her son, the elector George Louis, objected to any interference in that country, and Anne disliked all mention of her successor. An angry letter from Anne possibly hastened Sophia's death, which took place at Herrenhausen on June 8, 1714; less than two months later her son, George Louis, became king of Great Britain and Ireland as George I. on the death of Anne.

Rait, *Five Stuart Princesses* (London, 1902).

SOPHIA ALEKSYEEVNA (1657–1704), tsarevna and regent of Russia, was the third daughter of Tsar Alexius and Maria Miloslavskaya. Educated on semi-ecclesiastical lines by the learned monk of Kiev, Polotsky, she emancipated herself betimes from the traditional tyranny of the *terem,* or women's quarters. Setting aside court etiquette, she had nursed her brother Tsar Theodore III. in his last illness, and publicly appeared at his obsequies, though it was usual only for the widow of the deceased and his successor to the throne to attend that ceremony. Three days after little Peter, then in his fourth year, had been raised to the throne, she won over the *stryeltsy,* or musketeers, who at her instigation burst into the Kreml, murdering everyone they met, including Artamon Matvyeev, Peter's chief supporter, and Ivan Naruishkin, the brother of the tsaritsa-regent Natalia, Peter's mother (May 15–17, 1682). When the rebellion was over there was found to be no government. Everyone was panic-stricken and in hiding except Sophia, and to her, as the only visible representative of authority, the court naturally turned for orders. She paid off and pacified the *stryeltsy,* and secretly worked upon them to present (May 29) a petition to the council of state to the effect that her half-brother Ivan should be declared senior tsar, while Peter was degraded into the junior tsar. This duumvirate was but a stepping-stone to the ambition of Sophia, who thus became the actual ruler of Russia.

By Nov. 6, Sophia's triumph was complete. The conduct of foreign affairs she committed entirely to her paramour, Prince Vasily Golitsuin, while the crafty and experienced clerk of the council, Theodore Shaklovity, looked after domestic affairs and the treasury. Sophia's fondness for Golitsuin induced her to magnify his barely successful campaigns in the Crimea into brilliant triumphs which she richly rewarded, thus disgusting everyone who had the honour of the nation at heart. Most of the malcontents rested their hopes for the future on the young tsar Peter, who was the first to benefit by his sister's growing unpopularity. Sophia took council of Shaklovity, and it was agreed (1687) between them that the *stryeltsy* should be employed to dethrone Peter. The *stryeltsy,* however, received the whole project so coldly that it had to be abandoned. A second conspiracy to seize him in his bed (August 1689) was betrayed to Peter, and he fled to the fortress-monastery of Troitsa. Here all his friends rallied round him, including the bulk of the magnates, half the *stryeltsy,* and all the foreign mercenaries. From Aug. 12 to Sept. 7 Sophia endeavoured to set up a rival camp in the Kreml; but her professed adherents gradually left her. She was compelled to retire within the Novo-Dyevichy monastery, but without taking the veil. Nine years later (1698), on suspicion of being concerned in the rebellion of the *stryelsty,* she was shorn a nun and imprisoned for life.

See J. E. Zabyelin, *Domestic Conditions of the Russian Princes* (Rus.; Moscow, 1895); R. N. Bain, *The First Romanovs* (1905).

SOPHIA DOROTHEA (1666–1726), wife of George Louis, elector of Hanover (George I. of England), only child of George William, duke of Brunswick-Lüneburg-Celle, by a Huguenot lady named Eleanore d'Olbreuze (1639–1722), was born on Sept. 15, 1666. Sophia Dorothea was married, for dynastic reasons, to her cousin George Louis, son of Duke Ernest Augustus, who became elector of Hanover in 1692. This union was a very unhappy one. The electress Sophia hated her daughter-in-law, and this feeling was soon shared by the prince himself. Under these circumstances Sophia Dorothea made the acquaintance of Count Philipp Christoph von Königsmark (*q.v.*), who assisted her in one or two futile attempts to escape from Hanover, and rightly or wrongly was regarded as her lover. In 1694 the count was assassinated, and the princess was divorced and imprisoned at Ahlden, remaining in captivity until her death on Nov. 23, 1726. Sophia Dorothea is sometimes referred to as the "princess of Ahlden." Her two children were the English king, George II., and Sophia Dorothea, wife of Frederick William I. and mother of Frederick the Great.

SOPHISM, in logic and philosophy, is used in various senses. Sometimes it is synonymous with fallacy (*q.v.*) and means any inconclusive argument. Sometimes it denotes an invalid argument which is particularly difficult to refute, like the paradoxes of Zeno (*q.v.*). Lastly, it is also used in an offensive sense to denote an argument that is not only wrong and known to be wrong, but which is deliberately intended to deceive. *See* FALLACY, LOGIC.

SOPHISTS, the name given by the Greeks about the middle of the 5th century B.C. to certain teachers of a superior grade who, distinguishing themselves from philosophers on the one hand and from artists and craftsmen on the other, claimed to prepare their pupils, not for any particular study or profession, but for civic life (σοφιστής, literally, man of wisdom). For nearly a hundred years the sophists held almost a monopoly of general or liberal education. Yet, within the limits of the profession, there was considerable diversity both of theory and of practice. Four principal

varieties are distinguishable, and may be described as the sophistries of culture, of rhetoric, of politics and of "eristic," *i.e.*, disputation. Each of these predominated in its turn, though not to the exclusion of others, the sophistry of culture beginning about 447, and leading to the sophistry of eristic, and the sophistry of rhetoric taking root in central Greece about 427, and merging in the sophistry of politics. Further, since Socrates and the Socratics were educators, they too might be, and in general were, regarded as sophists; but, as they conceived truth—so far as it was attainable—rather than success in life, in the law court, in the assembly or in debate, to be the right end of intellectual effort, they were at variance with their rivals, and are commonly ranked by historians, not with the sophists, who confessedly despaired of knowledge, but with the philosophers, who, however unavailingly, continued to seek it. With the establishment of the great philosophical schools—first, of the Academy, next of the Lyceum—the philosophers took the place of the sophists as the educators of Greece.

The sophistical movement was then, primarily, an attempt to provide a general or liberal education which should supplement the customary instruction in reading, writing, gymnastics and music. But, as the sophists of the first period chose for their instruments grammar, style, literature and oratory, while those of the second and third developments were professed rhetoricians, sophistry exercised an important influence upon literature. Then again, as the movement, taking its rise in the philosophical agnosticism which grew out of the early physical systems, was itself persistently sceptical, sophistry may be regarded as an interlude in the history of philosophy. Finally, the practice of rhetoric and eristic, which presently became prominent in sophistical teaching, had, or at any rate seemed to have, a mischievous effect upon conduct; and the charge of seeking, whether in exposition or in debate, not truth but victory—which charge was impressively urged against the sophists by Plato—grew into an accusation of holding and teaching immoral and unsocial doctrines, and in our own day has been the subject of eager controversy.

Genesis and Development of Sophistry.—Sophistry arose out of a crisis in philosophy. The earlier Ionian physicists, Thales, Anaximander and Anaximenes, in their attempts to trace the Multiplicity of things to a single material element, had been troubled by no misgivings about the possibility of knowledge. But, when Heraclitus to the assumption of fire as the single material cause added the doctrine that all things are in perpetual flux, he found himself obliged to admit that things cannot be known. Thus, though, in so far as he asserted his fundamental doctrine without doubt or qualification, he was a dogmatist, in all else he was a sceptic. Again, the Eleatic Parmenides, deriving from the theologian Xenophanes the distinction between ἐπιήστμη and δόξα, conceived that, whilst the One exists and is the object of knowledge, the Multiplicity of things becomes and is the object of opinion; but, when his successor Zeno provided the system with a logic, the consistent application of that logic resolved the fundamental doctrine into the single proposition "One is One," or, more exactly, into the single identity "One One." Thus Eleaticism, though professedly dogmatic, was inconsistent in its theory of the One and its attributes, and openly sceptical in regard to the world of nature. Lastly, the philosophers of the second physical succession—Empedocles, Anaxagoras, Leucippus—not directly attacking the great mystery of the One and the Many, but in virtue of a scientific instinct approaching it through the investigation of phenomena, were brought by their study of sensation to perceive and to proclaim the inadequacy of the organs of sense. Thus they too, despite their air of dogmatism, were in effect sceptics. In short, from different standpoints, the three philosophical successions had devised systems which were in reality sceptical, though they had none of them recognized the sceptical inference.

Towards the middle of the 5th century, however, Protagoras of Abdera, taking account of the teaching of the first, and possibly of the second, of the physical successions, and Gorgias of Leontini, starting from the teaching of the metaphysical succession of Elea, drew that sceptical inference from which the philosophers had shrunk. If, argued Protagoras in a treatise entitled *Truth*, all things are in flux, so that sensation is subjective, it follows that "Man is the measure of all things, of what is, that it is, and of what is not, that is not"; in other words, there is no such thing as objective truth. Similarly, Gorgias, in a work *On Nature, or on the Nonent,* maintained (*a*) that nothing is, (*b*) that, if anything is, it cannot be known, (*c*) that, if anything is and can be known, it cannot be expressed in speech; and the summaries which have been preserved by Sextus Empiricus (*Adv. Math.* vii. 65–87) and by the author of the *De Melisso,* etc. (chs. 5, 6), show that, in defending these propositions, Gorgias availed himself of the arguments which Zeno had used to discredit the popular belief in the existence of the Many; in other words, that Gorgias turned the destructive logic of Zeno against the constructive ontology of Parmenides, thereby not only reducing Eleaticism to nothingness, but also, until such time as a better logic than that of Zeno should be provided, precluding all philosophical inquiry whatsoever. Thus, whereas the representatives of the three successions had continued to regard themselves as philosophers or seekers after truth, Protagoras and Gorgias, plainly acknowledging their defeat, withdrew from the ungrateful struggle.

Meagre as were the results which the earlier thinkers had obtained, the extinction of philosophy just at the time when the liberal arts became more technical and consequently less available as employments of leisure, threatened to leave a blank in Hellenic life. Accordingly Protagoras, while with the one hand he put away philosophy, with the other offered a substitute. Emphasizing the function of the teacher, which with the philosophers had been subordinate, and proclaiming the right end of intellectual endeavour to be, not "truth" (ἀλήθεια) or "wisdom" (σοφία), which was unattainable, but "virtue" or "excellence" (ἀρετή), he sought to communicate, not a theory of the universe, but an aptitude for civic life. "The lesson which I have to teach," Plato makes him say (*Prot.* 318 E), "is prudence or good counsel, both in respect of domestic matters that the man may manage his household aright, and in respect of public affairs, that he may be thoroughly qualified to take part, both by deed and by word, in the business of the state. In other words, I profess to make men good citizens." As instruments of education Protagoras used grammar, style, poetry and oratory. Thus, whereas hitherto the young Greek, having completed his elementary training in the schools of the γραμματιστής, the κιθαριστής, and the παιδοτρίβης, was left to prepare himself for his life's work as best he might, by philosophical speculation, by artistic practice, or otherwise, one who passed from the elementary schools to the lecture-room of Protagoras received from him a "higher education." The programme was exclusively literary, but for the moment it enabled Protagoras to satisfy the demand which he had discovered and evoked. Wherever he went, his lecture-room was crowded with admiring pupils, whose homage filled his purse and enhanced his reputation.

After Protagoras the most prominent of the literary sophists was Prodicus of Ceos. Establishing himself at Athens, he taught "virtue" or "excellence," in the sense attached to the word by Protagoras, partly by means of literary subjects, partly in discourses upon practical ethics. It is plain that Prodicus was an affected pedant; yet his simple conventional morality found favour, and Plato (*Rep.* 600 C) couples him with Protagoras in his testimony to the popularity of the sophists and their teaching.

At Athens, the centre of the intellectual life of Greece, there was soon to be found a host of sophists; some of them strangers, others citizens; some of them bred under Protagoras and Prodicus, others self-taught. In the teaching of the sophists of this younger generation two points are observable. First, their independence of philosophy and the arts being assured, though they continued to regard "civic excellence" as their aim, it was no longer necessary for them to make the assertion of its claims a principal element in their exposition. Secondly, for the sake of novelty they extended their range, including scientific and technical subjects, but handling them, and teaching their pupils to handle them, in a popular way. In this stage of sophistry then, the sophist, though not a specialist, trenched upon the provinces of specialists; and accordingly Plato (*Prot.* 318 E) makes Protagoras pointedly refer

to sophists who, "when young men have made their escape from the arts, plunge them once more into technical study, and teach them such subjects as arithmetic, astronomy, geometry and music." The sophist of whom the Platonic Protagoras is here thinking was Hippias of Elis, who gave popular lectures, not only upon the four subjects just mentioned, but also upon grammar, mythology, family history, archaeology, Homerology and the education of youth. In this polymath we see at once the degradation of the sophistry of culture and the link which connects Protagoras and Prodicus with the eristics, who at a later period taught, not, like Hippias, all branches of learning, but a universally applicable method of disputation.

Meanwhile, Gorgias of Leontini, who, as has been seen, had studied and rejected the philosophy of western Greece, gave to sophistry a new direction by bringing to the mother country the technical study of rhetoric—especially forensic rhetoric (Plato, *Gorg.* 454 B; *cf.* Aristotle, *Rhet.* 1354, b 26)—which study had begun in Sicily with Corax and Tisias nearly forty years before. Gorgias was already advanced in years and rich in honours when, in 427, he visited Athens as the head of an embassy sent to solicit aid against Syracuse. Received with acclamation, he spent the rest of his long life in central Greece, winning applause by the display of his oratorical gifts and acquiring wealth by the teaching of rhetoric. There is no evidence to show that at any period of his life he called himself a sophist; and, as Plato (*Gorg.* 449 A) makes him describe himself as a *ῥήτωρ,* it is reasonable to suppose that he preferred that title. That he should do so was only natural, since his position as a teacher of rhetoric was already secure when Protagoras made his first appearance in the character of a sophist; and, as Protagoras, Prodicus and the rest of the sophists of culture offered a comprehensive education, of which oratory formed only a part, whilst Gorgias made no pretence of teaching "civic excellence" (Plato, *Meno,* 95 C), and found a substitute for philosophy, not in literature generally, but in the professional study of rhetoric alone, it would have been convenient if the distinction between sophistry and rhetoric had been maintained. But though, as will be seen hereafter, these two sorts of education were sometimes distinguished, Gorgias and those who succeeded him as teachers of rhetoric, such as Thrasymachus of Chalcedon and Polus of Agrigentum, were commonly called by the title which Protagoras had assumed and brought into familiar use.

Rhetorical sophistry, as taught by Gorgias with special reference to the requirements of the law courts, led by an easy transition to political sophistry. During the century which had elapsed since the expulsion of the Peisistratids and the establishment of the democracy, the Athenian constitution had developed with a rapidity which produced an oligarchical reaction, and the discussion of constitutional principles and precedents, always familiar to the citizen of Athens, was thus abnormally stimulated. The Peloponnesian War, too, not only added a deeper interest to ordinary questions of policy, but also caused the relations of dissentient parties, of allied and belligerent states, of citizens and aliens, of bond and free, of Greeks and barbarians, to be eagerly debated in the light of present experience. It was only natural then that some of those who professed to prepare young Athenians for public life should give to their teaching a distinctively political direction; and accordingly we find Isocrates recognizing teachers of politics, and discriminating them at once from those earlier sophists who gave popular instruction in the arts and from the contemporary eristics. To this class, that of the political sophists, may be assigned Lycophron, Alcidamas and Isocrates himself. For, though that celebrated personage would have liked to be called, not "sophist" but "political philosopher," and tried to fasten the name of "sophist" upon his opponents the Socratics, it is clear from his own statement that he was commonly ranked with the sophists, and that he had no claim, except on the score of superior popularity and success, to be dissociated from the other teachers of political rhetoric. It is true that he was not a political sophist of the vulgar type, that as a theorist he was honest and patriotic, and that, in addition to his fame as a teacher, he had a distinct reputation as a man of letters; but he was a professor of political rhetoric, and, as such, in the phraseology of the day, a sophist. He had already reached the height of his fame when Plato opened a rival school at the Academy, and pointedly attacked him in the *Gorgias,* the *Phaedrus* and the *Republic.* Thenceforward, there was a perpetual controversy between the rhetorician and the philosopher, and the struggle of educational systems continued until, in the next generation, the philosophers were left in possession of the field.

While the sophistry of rhetoric led to the sophistry of politics, the sophistry of culture led to the sophistry of disputation. It has been seen that the range of subjects recognized by Protagoras and Prodicus gradually extended itself, until Hippias professed himself a teacher of all branches of learning, including in his list subjects taught by artists and professional men, but handling them from a popular or non-professional point of view. The successors of the polymath claimed to possess and to communicate, not the knowledge of all branches of learning, but an aptitude for dealing with all subjects, which aptitude should make the knowledge of any subject superfluous. In other words, they cultivated skill in disputation. Now skill in disputation is plainly a valuable accomplishment; and, as the Aristotelian logic grew out of the regulated discussions of the eristics and their pupils, the disputant sophistry of the 4th century deserves more attention and more respect than it usually receives from historians of Greek thought. But when men set themselves to cultivate skill in disputation, regarding the matter discussed not as a serious issue, but as a thesis upon which to practise their powers of controversy, they learn to pursue, not truth, but victory; and, their criterion of excellence having been thus perverted, they presently prefer ingenious fallacy to solid reasoning and the applause of bystanders to the consciousness of honest effort. Indeed, the sophists generally had a special predisposition to error of this sort, not only because sophistry was from the beginning a substitute for the pursuit of truth, but also because the successful professor, travelling from city to city, or settling abroad, could take no part in public affairs, and thus was not at every step reminded of the importance of the "material" element of exposition and reasoning. Paradox, however, soon becomes stale, and fallacy wearisome. Hence, despite its original popularity, eristical sophistry could not hold its ground. The man of the world who had cultivated it in his youth regarded it in riper years as a foolish pedantry, or at best as a propaedeutic exercise; while the serious student, necessarily preferring that form of disputation which recognized truth as the end of this, as of other intellectual processes, betook himself to one or other of the philosophies of the revival.

In order to complete this sketch of the development of sophistry in the latter half of the 5th century and the earlier half of the 4th, it is necessary next to take account of Socrates and the Socratics. A foe to philosophy and a renegade from art, Socrates took his departure from the same point as Protagoras, and moved in the same direction, that of the education of youth. Finding in the cultivation of "virtue" or "excellence" a substitute for the pursuit of scientific truth, and in disputation the sole means by which "virtue" or "excellence" could be attained, he resembled at once the sophists of culture and the sophists of eristic. But, inasmuch as the "virtue" or "excellence" which he sought was that of the man rather than that of the official, while the disputation which he practised had for its aim, not victory, but the elimination of error, the differences which separated him from the sophists of culture and the sophists of eristic were only less considerable than the resemblances which he bore to both; and further, though his whole time and attention were bestowed upon the education of young Athenians, his theory of the relations of teacher and pupil differed from that of the recognized professors of education, inasmuch as the taking of fees seemed to him to entail a base surrender of the teacher's independence. The principal characteristics of Socrates's theory of education were accepted, *mutatis mutandis,* by the leading Socratics. With these resemblances to the contemporary professors of education, and with these differences, were Socrates and the Socratics sophists or not? To this question there is no simple answer, yes or no. It is certain that Socrates's contemporaries regarded him as a sophist; and it was only reasonable that they should so regard him, because

in opposition to the physicists of the past and the artists of the present he asserted the claims of higher education. But, though according to the phraseology of the time he was a sophist, he was not a typical sophist—his principle that, while scientific truth is unattainable by man, right opinion is the only basis of right action, clearly differentiating him from all the other professors of "virtue." Again, as the Socratics—Plato himself, when he established himself at the Academy, being no exception—were, like their master, educators rather than philosophers, and in their teaching laid especial stress upon discussion, they, too, were doubtless regarded as sophists, not by Isocrates only, but by their contemporaries in general; and it may be conjectured that the disputatious tendencies of the Megarian school made it all the more difficult for Plato and others to secure a proper appreciation of the difference between dialectic, or discussion with a view to the discovery of truth, and eristic, or discussion with a view to victory. Changing circumstances, however, carry with them changes in the meaning and application of words. Whereas, so long as philosophy was in abeyance Socrates and the Socratics were regarded as sophists of an abnormal sort, as soon as philosophy revived it was dimly perceived that, in so far as Socrates and the Socratics dissented from sophistry, they preserved the philosophical tradition. This being so, it was found convenient to revise the terminology of the past, and to include in the philosophical succession those who, though not philosophers, had cherished the sacred spark. As for Socrates, he ranked himself neither with the philosophers, who professed to know, nor with the sophists, who professed to teach; and, if he sometimes described himself as a *φιλόσοφος* he was careful to indicate that he pretended to no other knowledge than that of his own limitations.

It would seem then, (1) that popular nomenclature included under the term "sophist" all teachers—whether professors, or like Socrates, amateurs—who communicated, not artistic skill, nor philosophical theory, but a general or liberal education; (2) that, of those who were commonly accounted sophists, some professed culture, some forensic rhetoric, some political rhetoric, some eristic, some (*i.e.*, the Socratics) dialectic; (3) that the differences between the different groups of sophists were not inconsiderable, and that in particular the teaching of the rhetoricians was distinct in origin, and, in so far as its aim was success in a special walk of life, distinct in character, from the more general teaching of the sophists of culture, the eristics, and the dialecticians, while the teaching of the dialecticians was discriminated from that of the rest, in so far as the aim of the dialecticians was truth, or at least the bettering of opinion; and, consequently, (4) that, in awarding praise and blame to sophistry and its representatives, the distinctive characteristics of the groups above enumerated must be studiously kept in view.

Lapse of time and change of circumstances brought with them not merely changes in the subjects taught, but also changes in the popular estimate of sophistry and sophists. The first and most obvious sentiment which sophistry evoked was an enthusiastic and admiring interest. The sophist seemed to his youthful hearers to open a new field of intellectual activity and thereby to add a fresh zest to existence. But in proportion to the fascination which he exercised upon the young was the distrust which he inspired in their less pliable elders. Not only were they dismayed by the novelty of the sophistical teaching, but also they vaguely perceived that it was subversive of authority, of the authority of the parent over the child as well as of the authority of the state over the citizen. Of the two conflicting sentiments, the favour of the young, gaining as years passed away, naturally prevailed; sophistry ceased to be novel, and attendance in the lecture-rooms of the sophists came to be thought not less necessary for the youth than attendance in the elementary schools for the boy. The lively enthusiasm and the furious opposition which greeted Protagoras had now burnt themselves out, and before long the sophist was treated by the man of the world as a harmless, necessary pedagogue.

Relations of Sophistry to Education, Literature and Philosophy.—If then the sophists, from Protagoras to Isocrates, were before everything educators, it becomes necessary to inquire whether their labours marked or promoted an advance in educational theory and method. At the beginning of the 5th century B.C. every young Greek of the better sort already received rudimentary instruction, not only in music and gymnastics, but also in reading and writing. Further, in the colonies, and especially the colonies of the West, philosophy and art had done something for higher education. Thus in Italy the Pythagorean school was, in the fullest sense of the term, an educational institution; and in Sicily the rhetorical teaching of Corax and Tisias was presumably educational in the same sense as the teaching of Gorgias. But in central Greece, where, at any rate down to the Persian Wars, politics, domestic and foreign, were all-engrossing, and left the citizen little leisure for self-cultivation, the need of a higher education had hardly made itself felt. The overthrow of the Persian invaders changed all this. Henceforward the best of Greek art, philosophy and literature gravitated to Athens, and with their concentration and consequent development came a general and growing demand for teaching. As has been seen, it was just at this period that philosophy and art ceased to be available for educational purposes, and accordingly the literary sophists were popular precisely because they offered advanced teaching which was neither philosophical nor artistic. Their recognition of the demand and their attempt to satisfy it are no small claims to distinction. That, whereas before the time of Protagoras there was little higher education in the colonies and less in central Greece, after his time attendance in the lecture-rooms of the sophists was the customary sequel to attendance in the elementary schools, is a fact which speaks for itself.

But this is not all. The education provided by the sophists of culture had positive merits. When Protagoras included in his course, grammar, style, interpretation of the poets and oratory, supplementing his own continuous expositions by disputations in which he and his pupils took part, he showed a not inadequate appreciation of the requisites of a literary education; and it may be conjectured that his comprehensive programme, which Prodicus and others extended, had something to do with the development of that versatility which was the most notable element in the Athenian character.

There is less to be said for the teachers of rhetoric, politics and eristic, who, in limiting themselves each to a single subject—the rhetoricians proper or forensic rhetoricians to one branch of oratory, the politicians or political rhetoricians to another, and the eristics to disputation—ceased to be educators and became instructors. Nevertheless, rhetoric and disputation, though at the present day strangely neglected in English schools and universities, are, within their limits, valuable instruments; and, as specialization in teaching does not necessarily imply specialization in learning, many of those who attended the lectures and the classes of a rhetorician or an eristic sought and found other instruction elsewhere. It would seem then that even in its decline sophistry had its educational use. But in any case it may be claimed for its professors that in the course of a century they discovered and turned to account most of the instruments of literary education.

With these considerable merits, normal sophistry had one defect, its indifference to truth. Despairing of philosophy—that is to say, of physical science—the sophists were prepared to go all lengths in scepticism. Accordingly the epideictic sophists in exposition, and the argumentative sophists in debate, one and all, studied, not matter but style, not accuracy but effect, not proof but persuasion. In short, in their hostility to science they refused to handle literature in a scientific spirit. That this defect was serious was dimly apprehended even by those who frequented and admired the lectures of the earlier sophists; that it was fatal was clearly seen by Socrates, who, himself commonly regarded as a sophist, emphatically reprehended, not only the taking of fees, which was after all a mere incident, objectionable because it seemed to preclude independence of thought, but also the fundamental disregard of truth which infected every part and every phase of sophistical teaching. To these contemporary censures the modern critic cannot refuse his assent.

To literature and to oratory the sophists rendered good service. Themselves of necessity stylists, because their professional suc-

cess largely depended upon skilful and effective exposition, the sophists both of culture and of rhetoric were professedly teachers of the rules of grammar and the principles of written and spoken discourse. Thus, by example as well as by precept, they not only taught their hearers to value literary and oratorical excellence, but also took the lead in fashioning the style of their time. Their influence in these respects was weighty and important. Whereas, when sophistry began, prose composition was hardly practised in central Greece, the sophists were still the leaders in literature and oratory when Plato wrote the *Republic,* and they had hardly lost their position when Demosthenes delivered the *Philippics.* In fact, it is not too much to say that it was the sophists who provided those great masters with their consummate instrument, and it detracts but little from the merit of the makers if they were themselves unable to draw from it its finer tones.

The relation of sophistry to philosophy was throughout one of pronounced hostility. From the days of Protagoras, when this hostility was triumphant and contemptuous, to the days of Isocrates, when it was jealous and bitter, the sophists were declared and consistent sceptics. But, although Protagoras and Gorgias had examined the teaching of their predecessors so far as to satisfy themselves of its futility and to draw the sceptical inference, their study of the great problem of the day was preliminary to their sophistry rather than a part of it; and, as the overthrow of philosophy was complete and the attractions of sophistry were all-powerful, the question "What is knowledge?" ceased for a time to claim or to receive attention. There is, then, no such thing as a "sophistical theory of knowledge." Similarly, the recognition of a "sophistical ethic" is, to say the least, misleading. It may have been that the sophists' preference of seeming to reality, of success to truth, had a mischievous effect upon the morality of the time; but it is clear that they had no common theory of ethics, and there is no warrant for the assumption that a sophist, as such, specially interested himself in ethical questions. When Protagoras asserted "civic excellence" or "virtue" to be the end of education, he neither expressed nor implied a theory of morality. Prodicus in his platitudes reflected the customary morality of the time. Gorgias said plainly that he did not teach "virtue." If Hippias, Polus and Thrasymachus defied conventional morality, they did so independently of one another, and in this, as in other matters, they were disputants maintaining paradoxical theses, rather than thinkers announcing heretical convictions. The morality of Isocrates bore a certain resemblance to that of Socrates. In short, the attitude of the sophists towards inquiry in general precluded them, collectively and individually, from attachment to any particular theory. Yet among the so-called sophists there were two who had philosophical leanings, as appears in their willingness to be called by the title of philosopher. First, Socrates, whilst he conceived that the physicists had mistaken the field of inquiry, absolute truth being unattainable, maintained, as has been seen, that one opinion was better than another, and that consistency of opinion, resulting in consistency of action, was the end which the human intellect properly proposes to itself. Hence, though an agnostic, he was not unwilling to be called a philosopher, in so far as he pursued such truth as was attainable by man. Secondly, when sophistry had begun to fall into contempt, the political rhetorician Isocrates claimed for himself the time-honoured designation of philosopher, "herein," says Plato, "resembling some tinker, bald-pated and short of stature, who, having made money, knocks off his chains, goes to the bath, buys a new suit, and then takes advantage of the poverty and desolation of his master's daughter to urge upon her his odious addresses" (*Rep.* vi. 495 E). It will be seen, however, that neither Socrates nor Isocrates was philosopher in any strict sense of the word, the speculative aims of physicists and metaphysicians being foreign to the practical theories both of the one and of the other.

On the later use of the term "sophist," *see* RHETORIC. (H. JN.)

SOPHOCLES (495–406 B.C.), Greek tragic poet, the son of Sophillus, was born at Colonus in the neighbourhood of Athens. The date assigned for the poet's birth is in accordance with the tale that young Sophocles, then a pupil of the musician Lamprus, was chosen to lead the chorus of boys in the celebration of the victory of Salamis (480 B.C.). The time of his death is fixed by the allusions to it in the *Frogs* of Aristophanes and in the *Muses,* a lost play of Phrynichus, the comic poet, which were both produced in 405 B.C. Apart from tragic victories, the event of Sophocles' life most fully authenticated is his appointment, at the age of 55, as one of the generals who served with Pericles in the Samian War (440–439 B.C.). Conjecture has been rife as to the possibility of his here improving acquaintance with Herodotus, whom he probably met some years earlier at Athens. But the distich quoted by Plutarch—

> *'Ωιδὴν Ἡροδότῳ τεῦξεν Σοφοκλῆς ἐτέων ὢν*
> *Πέντ' ἐπὶ πεντήκοντα*—

is a slight ground on which to reject the stronger tradition, according to which Herodotus was ere this established at Thurii. The fact of Sophocles' generalship is the less surprising if taken in connection with the interesting remark of his biographer (whose *Life,* though absent from the earliest ms. through some mischance, bears marks of an Alexandrian origin) that he took his full share of civic duties, and even served on foreign embassies. The large acquaintanceship which this implies, not only in Athens, but in Ionic cities generally, is a point of main importance in considering the opportunities of information at his command.

The testimony borne by Aristophanes in the *Frogs* to the amiability of the poet's temper (*ὁ δ' εὔκολος μὲν ἐνθάδ', εὔκολος δ' ἐκεῖ*) agrees with the record of his biographer that he was universally beloved. And the anecdote recalled by Cephalus in Plato's *Republic,* that Sophocles welcomed the release from the passions which is brought by age, accords with the spirit of his famous Ode to Love in the *Antigone.* The Sophocles who, according to Aristotle (*Rhet.* iii. 18), said of the government of the Four Hundred that it was the better of two bad alternatives (probably the same who was one of the *probuli*), may or may not have been the poet. Other gossiping stories are hardly worth repeating—as that Pericles rebuked his love of pleasure and thought him a bad general, though a good poet; that he humorously boasted of his own "generalship" in affairs of love; or that he said of Aeschylus that he was often right without knowing it, and that Euripides represented men as they are, not as they ought to be. (This last anecdote has the authority of Aristotle.) And the story of his indictment by his son, Iophon, for incompetence to manage his affairs—to which Cicero has given some weight by quoting it in the *De senectute*—appears to be really traceable to Satyrus (*fl. c.* 200 B.C.), the same author who gave publicity to the most ridiculous of the various absurd accounts of the poet's death—that his breath failed him for want of a pause in reading some passage of the *Antigone.* Satyrus is at least the sole authority for the defence of the aged poet, who, after reciting passages from the *Oed. Col.,* is supposed to have said to his accusers, "If I am Sophocles I am no dotard, and if I dote I am not Sophocles."

There is a tradition that Sophocles, because of the weakness of his voice, was the first poet who desisted from acting in his own plays. Various minor improvements in decoration and stage carpentry are attributed to him. It is more interesting, if true, that he wrote his plays having certain actors in his eye; that he formed an association for the promotion of liberal culture; and that he was the first to introduce three actors on the stage. It is asserted on the authority of Aristoxenus that Sophocles was also the first to employ Phrygian melodies. Ancient critics had also noted his familiarity with Homer, especially with the *Odyssey,* his power of selection and of extracting an exquisite grace from all he touched (whence he was named the "Attic Bee"), his mingled felicity and boldness, and, above all, his subtle delineation of human nature

and feeling.

His minor poems, elegies, paeans, etc., have all perished; and of his 100 and odd dramas only seven remain. These all belong to the period of his maturity (he had no decline); and not only the titles but some scanty fragments of more than 90 others have been preserved. Suïdas says that "Sophocles began the practice of pitting play against play, instead of the tetralogy." If it were meant that Sophocles did not exhibit tetralogies, this statement would have simply to be rejected. For the word of Suïdas (A.D. 950) has no weight against quotations from the lists of tragic victories (διδασκαλίαι), which there is no other reason for discrediting. But it seems probable that the trilogy had ceased to be the continuous development of one legend or cycle of legends—if, indeed, it ever was so exclusively; and if a Sophoclean tetralogy was still linked together by some subtle bond of tragic thought or feeling, this would not affect the criticism of each play considered as an artistic whole. And these changes, or something like them, may have given rise to the statement of Suïdas.

If the diction of Sophocles sometimes reminds his readers of the *Odyssey*, the subjects of his plays were more frequently chosen from those later epics which subsequently came to be embodied in the epic cycle, including probably, though there is no mention of such a thing, some early version of the Argonautic story. In one or other of these heroic poems the legends of all the great cities of Hellas were by this time embodied, and Sophocles drew from these the materials for his more concentrated art, much as Shakespeare made use of Hollingshed or Plutarch, or as the subjects of Tennyson's *Idylls of the King* were taken from Sir Thomas Malory.

The principle of selection seems to have been simply his perception of the tragic possibilities of a particular fable. But to say that subsidiary or collateral motives were never present to Sophocles in the selection of a subject would be beyond the mark. His first drama, the *Triptolemus*, must have been full of local colouring; the *Ajax* appealed powerfully to the national pride; and in the *Oedipus Coloneus* some faint echoes even of oligarchical partisanship may be possibly discerned (*see* below). But even where they existed, such motives *were* collateral and subsidiary; they were never primary. All else was subordinated to the dramatic, or, in other words, the purely human, interest of the fable. This central interest is even more dominant and pervading in Sophocles than the otherwise supreme influence of religious and ethical ideas. The idea of destiny, for example, was of course inseparable from Greek tragedy. Its prevalence was one of the conditions which presided over the art from its birth, and, unlike Aeschylus, who wrestles with gods, Sophocles simply accepts it, both as a *datum* of tradition and a fact of life. But in the free handling of Sophocles even fate and providence are adminicular to tragic art. They are instruments through which sympathetic emotion is awakened, deepened, intensified. And, while the vision of the eternal and unwritten laws was holier yet, for it was not the creation of any former age, but rose and culminated with the Sophoclean drama, still to the poet and his Periclean audience this was no abstract notion, but was inseparable from their impassioned contemplation of the life of man—so great and yet so helpless, aiming so high and falling down so far, a plaything of the gods and yet essentially divine.

Sophocles is often praised for skilful construction. But the secret of his skill depends in large measure on the profound way in which the central situation in each of his fables has been conceived and felt. Concentration is the distinguishing note of tragedy, and it is by greater concentration that Sophocles is distinguished from other tragic poets. In the *Septem contra Thebas* or the *Prometheus* of Aeschylus there is still somewhat of epic enlargement and breadth; in the *Hecuba* and other dramas of Euripides separate scenes have an idyllic beauty and tenderness which affect us more than the progress of the action as a whole. But in following a Sophoclean tragedy we are carried steadily and swiftly onward, looking neither to the right nor to the left; the more elaborately any scene or single speech is wrought the more does it contribute to enhance the main emotion, and if there is a deliberate pause it is felt either as a welcome breathing space or as the calm of brooding expectancy.

The seven extant tragedies probably owe their preservation to some selection made for educational purposes in Alexandrian times. A yet smaller "syllogè" of three plays (*Ajax, Electra, Oedipus Tyrannus*) continued current amongst Byzantine students and many more copies of these exist than is the case with the other four. Of these four the *Antigone* seems to have been the most popular, while an inner circle of readers were specially attracted by the *Oedipus Coloneus.*

No example of the poet's earliest manner has come down to us. The *Antigone* certainly belongs to the Periclean epoch. Modern readers have thought it strange that Creon, when convinced, goes to bury Polynices before attempting to release Antigone. It is obvious how this was necessary to the catastrophe, but it is also true to character, for Creon is not moved by compunction for the maiden nor by anxiety on Haemon's account, but by the fear of retribution coming on himself and the State, because of the sacred law of sepulture which he has defied. Antigone is the martyr of natural affection and of the religion of the family. But, as Kaibel pointed out, she is also the high-born Cadmean maiden, whose defiance of the oppressor is accentuated by the pride of race. She despises Creon as an upstart, who has done outrage not only to eternal ordinance, but to the rights of the royal house.

The *Ajax,* that tragedy of wounded honour, still bears some traces of Aeschylean influence, and may be even earlier than the *Antigone.* The construction of the *Ajax* has been adversely criticized, but without sufficient reason. If it has not the concentration of the *Antigone*, or of the *Oedipus Tyrannus,* it has a continuous movement which culminates in the hero's suicide, and develops a fine depth of sympathetic emotion in the sequel.

In the *King Oedipus* the poet attains to the supreme height of dramatic concentration and tragic intensity. The drama seems to have been produced soon after the outbreak of the Peloponnesian War. The worship of the Delphic Apollo is associated with a profound sense of the value and sacredness of domestic purity, and in the command to drive out pollution there is possibly an implied reference to the expulsion of the Alcmaeonidae.

The *Electra*, a less powerful drama, is shown by the metrical indications to be somewhat later than the *Oedipus Rex.* Electra's heroic impulse, the offspring of filial love, through long endurance hardened into a "fixed idea," is irrepressible, and Orestes, supported by Pylades, goes directly to his aim in obedience to Apollo. But nothing can exceed the tenderness of the recognition scene—lines 1098–1321, and the description of the falsely reported chariot race (681–763) is full of spirit.

In the *Trachinian Maidens* there is a transition towards that milder pathos which Sophocles is said to have finally approved (ἠθικώτατον καὶ ἄριστον). The fate of Deianira is tragic indeed. But in her treatment of her rival, Iole, there are modern touches reminding one of Shakespeare. The play may have been produced at a time not far removed from the peace of Nicias. The "modern" note is even more conspicuous in the *Philoctetes,* where the inward conflict in the mind of Neoptolemus, between ambition and friendship, is delineated with equal subtlety and force, and the contrast of the ingenuous youth with the aged solitary, in whom just resentment has become a dominant idea, shows great depth of psychological insight. The contending interests are reconciled by the intervention of the deified Heracles. The *Philoctetes* is known to have been produced in the year 408 B.C., when Sophocles was 87 years old. The *Oedipus Coloneus* is said to have been brought out after the death of Sophocles by his grandson in the archonship of Micon, 402 B.C. Theseus in Euripides (*Supplices*) is the first citizen of a republic. In this drama he is the king whose word is law, and he is warned by Oedipus to avoid the madness of revolutionary change (lines 15,361–538). The tragic story of Oedipus is resumed, but in a later and deeper strain of thoughtful emotion. Once more the noble spirit, rejected by man, is accepted by the gods. The eternal laws have been vindicated. Their decrees are irreversible, but the involuntary unconscious criminal is not finally condemned. He has no more hope in this world, but is in mysterious communion with unseen powers. The sufferer is now a holy person and an author of blessing.

The spectator of a Sophoclean tragedy was invited to witness the supreme crisis of an individual destiny, and was possessed at the outset with the circumstances of the decisive moment. Except in the *Trachiniae,* where the retrospective soliloquy of Deianira is intended to emphasize her lonely position, this exposition is effected through a brief dialogue, in which the protagonist may or may not take part. In the *Oedipus Tyrannus* the king's entrance and his colloquy with the aged priest introduce the audience at once to the action and to the chief person. In the *Ajax* and *Philoctetes* the entrance or discovery of the hero is made more impressive by being delayed. Immediately after the prologos the chorus enter, numbering 15, either chanting in procession as in the *Antigone* and *Oedipus Tyrannus,* or dispersedly as in the *Oedipus Coloneus* and *Philoctetes,* or, thirdly, as in the *Electra,* where, after entering silently during the monody of the heroine, and taking up their position in the orchestra, they address her one by one. With one exception, the chorus, having once entered, remain to the end. They always stand in some carefully adjusted relation to the principal figure. The elders of Thebes, whose age and coldness throw into relief the fervour and the desolation of Antigone, are the very men to realize the calamity of Oedipus, and, while horror-stricken, to lament his fall. The rude Salaminian mariners are loyal to Ajax, but cannot enter into his grief. The Trachinian maidens would gladly support Deianira, who has won their hearts, but they are too young and inexperienced for the task. The noble Argive women can sympathize with the sorrows of Electra, but no sympathy can soothe her distress.

The parodos of the chorus is followed by the first scene or epeisodion, with which the action may be said to begin. For in the course of this the spectator's interest is strongly roused by some new circumstance involving an unforeseen complication—the awakening of Ajax (*Aj.*), the burial of Polynices (*Ant.*), the dream of Clytaemnestra (*El.*), the dark utterance of Teiresias (*Oed. Tyr.*), the arrival of Lichas with Iole (*Trach.*), the report of Ismene announcing Creon's coming (*Oed. Col.*), the sudden entreaty of Philoctetes crossed by the entrance of the pretended mariner (*Phil.*). The action from this point onwards is like a steadily flowing stream into which a swift and turbulent tributary has suddenly fallen, and the interest advances with rapid and continuous climax until the culmination is reached and the catastrophe is certain. The manner in which this is done, through the interweaving of dialogue and narration with the various lyrical portions, is very different in different dramas, one of the principal charms of Sophocles being his power of ingenious variation in the employment of his resources. Not less admirable is the strength with which he sustains the interest after the *peripeteia,* whether, as in the *Antigone,* by heaping sorrow upon sorrow, or, as in the first *Oedipus,* by passing from horror to tenderness and unlocking the fountain of tears. (A tragic action has five stages, whence the five acts of the modern drama: the start, the rise, the height, the change, the close.) The extreme point of boldness in arrangement is reached in the *Ajax,* where the chorus of Tecmessa, having been warned of the impending danger, depart severally in quest of the vanished hero, and thus leave not only the stage but the orchestra vacant for the soliloquy that precedes his suicide.

The proportion of the lyrics to the level dialogue is considerably less on the average in Sophocles than in Aeschylus, as might be expected from the development of the purely dramatic element, and the consequent subordination of the chorus to the protagonist. In the seven extant plays the lyrical portion ranges from one-fifth to nearly one-third, being highest in the *Antigone* and lowest in the *Oedipus Tyrannus.*

The union of strict symmetry with freedom and variety, which is throughout characteristic of the work of Sophocles, is especially noticeable in his handling of the tragic metres. In the iambics of his dialogue, as compared with those of Aeschylus, there is an advance which may be compared with the transition from "Marlowe's mighty line" to the subtler harmonies of Shakespeare. Felicitous pauses, the linking on of line to line, trisyllabic feet introduced for special effects, alliteration both hard and soft, length of speeches artfully suited to character and situation, adaptation of the caesura to the feeling expressed, are some of the points which occur most readily in thinking of his *senarii.* A minute speciality may be noted as illustrative of his manner in this respect. Where a line is broken by a pause towards the end and the latter phrase runs on into the following lines, elision sometimes takes place between the lines, e.g. (*Oed. Tyr.,* 332–333):—

Ἐγὼ οὔτ' ἐμαυτὸν οὔτε σ' ἀλγυνῶ. τί ταῦτ'
ἄλλως ἐλέγχεις

This is called *synaphea,* and is peculiar to Sophocles.

He differentiates more than Aeschylus does between the metres to be employed in the *κομμοί* (including the *κομματικά*) and in the choral odes. The dochmius, cretic, and free anapaest are employed chiefly in the *κομμοί.* In the stasima he has greatly developed the use of logaedic and particularly of glyconic rhythms, and far less frequently than his predecessor indulges in long continuous runs of dactyls or trochees. The light trochaic ⏑́ ⏑ — ⏑ ⏑́ ⏑ —, so frequent, in Aeschylus, is comparatively rare in Sophocles. If, from the very severity with which the choral element is subordinated to the purely dramatic, his lyrics have neither the magnificent sweep of Aeschylus nor the "linked sweetness" of Euripides, they have a concinnity and point, a directness of aim, and a truth of dramatic keeping, more perfect than is to be found in either. And even in grandeur it would be hard to find many passages to bear comparison with the second stasimon, or central ode, either of the *Antigone* (*εὐδαίμονες οἷσι κακῶν*) or the first *Oedipus* (*εἴ μοι ξυνείη φέροντι*). Nor does anything in Euripides equal in grace and sweetness the famous eulogy on Coloneus (the poet's birthplace) in the *Oedipus Coloneus.*

Bibliography.—Sophocles was edited (probably from the Venetian mss.) by Aldus Manutius, with the help of Musurus, in 1502. The Juntine editions, in which the text of Aldus was slightly modified with the help of Florentine mss., were published in 1522, 1547, respectively. An edition of the Scholia, very nearly corresponding to those on the margin of the Medicean or chief Laurentian ms. (La or L), previously appeared at Rome in 1518. The first great modification of the text was due to Turnebus, who had access to the Parisian mss.; but he was not fortunate in his selection. The earliest editors had been aware that the traditional arrangement of the metres was faulty, but little way had been made towards a readjustment. Now it so happens that the Parisian ms. T, which is a copy of the recension of Triclinius, an early 14th century scholar, contains also the metrical views of the same editor; and, having found (as he erroneously supposed) a sound authority, Turnebus (1552) blindly adopted it, and was followed in this by H. Stephanus (1568), and by Canter in Holland (1579), who was the first to recognize the arrangement of the odes in strophe and antistrophe. The error was to a large extent corrected by Brunck (1786), who rightly preferred Par. A (2712), a 13th century ms., belonging, as it happened, to the same family with Ven. 467, which Aldus had mainly followed. Thus after nearly three centuries the text returned (though with conjectural variations) into the former channel. Musgrave's edition was published posthumously in 1800, and Gilbert Wakefield had published a selection shortly before. Erfurdt in Germany then took up the succession, and his edition formed the basis of Hermann's, whose psychological method set the example of a new style of commentary which was adopted by Wunder. A new era commenced with Peter Elmsley's collation of the Laurentian ms. (made in 1818, but only published in full after his death). His transcription of the Scholia still exists in the Bodleian library. The most important German commentaries since Hermann's have been those of L. Campbell (1871–81); N. Wecklein, (1875–80); F. W. Schneidewin (7 vols., 1880–86); R. C. Jebb (7 vols., with Eng. trans., 1885–96). *See* also *Sophocles* (Greek and English trans. F. Star, Loeb ed., 2 vols., 1912–13); *Sophocles* (Greek and French, P. Masqueray, 1922, etc.). Editions of one or more dramas worth consulting are: P. Elmsley, *Oedipus Tyrannus* (1821) and *Oedipus Coloneus* (1823); C. A. Lobeck, *Ajax* (1835); A. Böckl, *Antigone* (1843); J. W. Donaldson, *Antigone* (1848); O. Jahn, *Electra* (1872); J. William White, *Oedipus Tyrannus* (1889); J. E. Sheppard, *Oedipus Tyrannus* (Greek and English, 1920). *See* G. Kaibel, *De Sophoclis Antigona* (1897). There are many translations into modern languages. *See* R. C. Jebb, *The Tragedies of Sophocles* (prose, reprinted in 1 vol., 1905). *See* also L. Campbell, *Tragic Drama in Aeschylus, Sophocles and Shakespeare* (1904); J. W. MacKail, *Lectures on Greek Poetry* (1911); and A. E. Haigh, *The Attic Theatre* (rev. A. W. Pickard, Cambridge, 1907).

SOPHRON, of Syracuse, writer of mimes, flourished about 430 B.C. He was the author of prose dialogues in the Doric dialect, containing both male and female characters, some serious, others humorous in style, and depicting scenes from the daily

life of the Sicilian Greeks. Plato is said to have been devoted to them. Some idea of their general character may be gathered from the 2nd and 15th idylls of Theocritus, which are said to have been imitated from Sophron.

Fragments edit. in H. L. Ahrens, *De graecae linguae dialectis* (1843), ii.; separately by C. J. Botzon (1867); and *see* his *De Sophrone et Xenarcho mimographis* (1856).

SOPRANO (a variant of Ital. *sovrano,* supreme, sovereign), in music, the highest class of human voice, the term being often restricted to that range in the female voice, "treble" being used of a boy's voice. Male *soprani,* either natural or artificially produced, as formerly in the *castrati* of the papal choirs (*see* EUNUCH), are also found.

SOPRON, a town in west Hungary commanding an important route from Transdanubia to Vienna through the so-called "Odenburg Gate" between the Leitha Mts. and Rosalien Mts. Through this gap German forms of culture have penetrated and Sopron has in part the appearance of a west European town. The critical site has been continuously occupied since pre-Roman times, a Roman colony, *Scarabantia,* having existed there, and has a wealth of old buildings, notably the 13th century Benedictine church, the 15th century church of St. Michael in Gothic style and the 17th century Dominican church. Pop. (1920), 35,248, about 50% German.

SOPWITH, THOMAS OCTAVE MURDOCH (1888–), British airman and inventor, was educated at Cottesmore and at Seafield Engineering college. Having won the Baron de Forest Prize of £4,000 for a flight from England to the Continent in 1910, in 1912 he founded the Sopwith Aviation Co., Ltd., at Kingston-on-Thames. During the World War this firm designed and produced large numbers of aeroplanes and seaplanes for the British Government. Sopwith also became joint managing director of the H. G. Hawker Engineering Co., Ltd., Kingston-on-Thames. In 1918 he was made a C.B.E. He married in 1914 Beatrix, daughter of the 8th Baron Ruthven.

SORA, a city of Campania, Italy, in the province of Frosinone 77 m. N. by W. of that town on the railway between Roccasecca and Avezzano, 920 ft. above sea-level. Pop. (1911), 9,781 (town); 17,612 (commune). It is built in a plain on the banks of the Liris. This part of the valley is the seat of some important paper-mills and other factories. On the precipitous rock above the town (1,768 ft.) which guards the Liris valley and the entrance to the Abruzzi are remains of polygonal walls of the citadel of the original Volscian town. There are also remains of mediaeval fortifications, and the Cathedral is a building of 1229.

Sora, an ancient Volscian town, was thrice captured by the Romans, in 345, 314 and 305 B.C., before they managed, in 303, by means of a colony 4,000 strong, to confirm its annexation. Under Augustus it was colonized by soldiers of the legio IV. Sorana, which had been mainly enrolled there. Sora was the birthplace of the Decii, Attilius Regulus, and Lucius Mummius.

See A. Lauri, Sora (Isola del Liri, 1913).

SORABJI, CORNELIA (1866–), Indian author and publicist, born at Nasik, was a daughter of the Rev. Sorabji Kharsedji, an agent of the Church Missionary Society at Poona, and of Francina Sorabji, a Hindu convert and educational pioneer. The first girl student of the Deccan college, Poona, Cornelia graduated in 1887, went to Somerville, Oxford, in 1888 as a scholar, and in 1893 received the B.C.L. of Oxford. In 1904 she was appointed a legal adviser to the court of wards, Bengal, and later held the same position in Behar and Orissa, and Assam. In these and other provinces she rendered very effective service to female landowners who suffered from the handicap of the *purdah* system. Miss Sorabji was awarded the Kaisar-i-Hind gold medal in 1909 and received the bar of the first class in 1922. She was enrolled in 1921 as a vakil of the Allahabad High Court. In 1923, soon after the removal of the sex disqualification she was called to the bar by Lincoln's Inn, and returned to India to practise.

Her best known books were *Love and Life Behind the Purdah* (1901) and *Sun-Babies* (1904), of which there was a second series in 1920. She also published *Between the Twilights* (1908), *Indian Tales of the Great Ones* (1916), the *Purdahnashin* (1917) and *Therefore* (1924).

SORACTE, a mountain in the province of Rome, Italy. It is a narrow, isolated limestone ridge, some 5 m. S.E. of Civita Castellana, and 3½ m. in length. The highest summit is 2,267 ft. above sea-level; just below is a monastery originally founded about 748 by Carloman, son of Charles Martel (the altar has fragments of sculptures of this period). Owing to the isolated position of the mountain the view is magnificent, and Soracte is a conspicuous object in the landscape, being visible from Rome.

SORANUS, Greek physician, born at Ephesus, lived during the reigns of Trajan and Hadrian (A.D. 98–138). According to Suïdas, he practised in Alexandria and subsequently in Rome. He was the chief representative of the school of physicians known as "methodists." Two treatises by him are extant: *On Fractures* (in J. L. Ideler, *Physici et medici minores,* i. 1841) and *On Midwifery and the Diseases of Women* (first printed in 1838, later by V. Rose, in 1882, with a 6th-century Latin translation by Moschio). The work of Soranus on midwifery was the source of many works on obstetrics; the book also contains a chapter on the care and feeding of infants. Of his most important work (*On Acute and Chronic Diseases*) only a few fragments in Greek remain, but we possess a complete Latin translation by Caelius Aurelianus (5th century). The *Life of Hippocrates* (in Ideler) probably formed one of the collection of medical biographies by Soranus referred to by Suïdas, and is valuable as the only authority for the life of the great physician, with the exception of articles in Suïdas and Stephanus of Byzantium (*s.v.* Κώς).

See article by J. Hahn, in Dechambre's *Dictionnaire encyclopédique des sciences médicales,* 3rd series, tom. 10; W. Christ, *Geschichte der griechischen Litteratur* (1808); J. Ilberg, *Die Überlieferung der Gynaekologie des Soranos von Ephesos* (Leipzig, 1910).

SORAU, a town in the Prussian province of Brandenburg, on the Sorebach, 54 m. S.E. of Frankfort-on-Oder by rail, and at the junction of lines to Kottbus and Görlitz. Pop. (1925) 18,363. Sorau is said to have existed in 840, and to have belonged to the abbey of Fulda till the 12th century. It received civic rights in 1260. The surrounding district formed the barony of Sorau, and in 1400 was united with the barony of Triebel. The last Count of Promnitz sold both baronies in 1765 to the elector of Saxony. In 1815 Saxony ceded them to Prussia. One of the oldest towns in Lower Lusatia, Sorau contains a number of churches (one dating from 1204), a town hall, built in 1260, and an old palace of 1207 (now a prison).

SORBONNE: *see* PARIS UNIVERSITY.

SORBS, the tribal name of the Slavonic people, whom the Germans call Wends in Lusatia (Lausitz); they call themselves Serbs or Lužičane. Their country includes the western extremity of Saxony and parts of Prussia; they are now surrounded by Germans. In the Middle Ages the protection of Nordic stock against Wendish blood was secured by monopolizing civil rights. The Sorbs are divided into High and Low along a line from Sagan to Muskau and Spremberg. Some Sorbs are Protestants, though the Saxon Sorbs are mostly Roman Catholics.

The two dialects stand between Polish and Czech. Sorb is usually printed in German blackletter variously adapted; the *Macica* publishes some books spelt after the Czech system.
